Preface

Format and Content of *Intravenous Medications*

Key to Abbreviations

Important IV Therapy Facts

Resources

Preparation and Administration of Injectable Drugs
IV Drugs

Generic drugs: A

A

- ABATACEPT
- ACETAMINOPHEN
- ACETAZOLAMIDE SODIUM
- ACETYLCYSTEINE INJECTION
- ACYCLOVIR
- ADENOSINE

ADO-TRASTUZUMAB EMTANSINE

ADUCANUMAB

AGALSIDASE BETA

ALBUMIN (HUMAN)

ALDESLEUKIN

ALEMTUZUMAB

ALFENTANIL HYDROCHLORIDE

ALGLUCERASE

ALGLUCOSIDASE ALFA

ALLOPURINOL SODIUM

ALPHA1-PROTEINASE INHIBITOR (HUMAN)

ALPROSTADIL

ALTEPLASE

AMIFOSTINE

AMIKACIN SULFATE

AMINOCAPROIC ACID

AMINOPHYLLINE

AMIODARONE HYDROCHLORIDE

AMISULPRIDE

AMMONIUM CHLORIDE

AMOBARBITAL SODIUM

AMPHOTERICIN B* ■ AMPHOTERICIN B LIPID-BASED PRODUCTS

AMPICILLIN SODIUM

AMPICILLIN SODIUM AND SULBACTAM SODIUM

ANGIOTENSIN II INJECTION

ANIDULAFUNGIN

ANTHRAX IMMUNE GLOBULIN INTRAVENOUS (HUMAN)

ANIFROLUMAB

ANTIHEMOPHILIC FACTOR (HUMAN ■ RECOMBINANT ■ RECOMBINANT [Fc FUSION PROTEIN] ■ RECOMBINANT [PEGYLATED] ■ RECOMBINANT [PEGYLATED-aucl] ■ RECOMBINANT [SINGLE CHAIN] ■ RECOMBINANT [PORCINE SEQUENCE])

ANTIHEMOPHILIC FACTOR ■ VON WILLEBRAND FACTOR COMPLEX (HUMAN)

ANTI-INHIBITOR COAGULANT COMPLEX

ANTITHROMBIN III (HUMAN)

ANTITHROMBIN RECOMBINANT

ANTI-THYMOCYTE GLOBULIN (RABBIT)

ANTIVENIN (LATRODECTUS MACTANS)

ANTIVENIN (MICRURUS FULVIUS)

ANTIVENIN CROTALIDAE POLYVALENT IMMUNE FAB (OVINE)

APREPITANT

ARGATROBAN

ARGININE HYDROCHLORIDE

ARSENIC TRIOXIDE

ASCORBIC ACID

ATEZOLIZUMAB

ATRACURIUM BESYLATE

ATROPINE SULFATE

AVALGLUCOSIDASE ALFA

AVELUMAB

AXICABTAGENE CILOLEUCEL SUSPENSION

- AZACITIDINE
- AZATHIOPRINE SODIUM
- AZITHROMYCIN
- AZTREONAM

Generic drugs: B

B

- BASILIXIMAB
- BELATACEPT
- BELIMUMAB
- BELINOSTAT
- BENDAMUSTINE HYDROCHLORIDE
- BENZTROPINE MESYLATE
- BEVACIZUMAB ▪ BEVACIZUMAB-awwb ▪ BEVACIZUMAB-bvzr
- BEZLOTOXUMAB
- BIVALIRUDIN
- BLEOMYCIN SULFATE
- BLINATUMOMAB
- BORTEZOMIB
- BOTULISM IMMUNE GLOBULIN (INTRAVENOUS HUMAN)
- BRENTUXIMAB VEDOTIN
- BREXANOLONE
- BRIVARACETAM
- BUMETANIDE
- BUPRENORPHINE HYDROCHLORIDE
- BUSULFAN

- BUTORPHANOL TARTRATE

Generic drugs: C

C

- C1 ESTERASE INHIBITOR (HUMAN OR RECOMBINANT)
- CABAZITAXEL
- CAFFEINE AND SODIUM BENZOATE
- CAFFEINE CITRATE
- CALASPARGASE PEGOL-mknl
- CALCITRIOL
- CALCIUM CHLORIDE
- CALCIUM GLUCONATE
- CANGRELOR
- CAPREOMYCIN
- CARBOPLATIN
- CARFILZOMIB
- CARMUSTINE (BCNU)
- CASIMERSEN
- CASPOFUNGIN ACETATE
- CEFAZOLIN SODIUM
- CEFEPIME HYDROCHLORIDE
- CEFIDEROCOL
- CEFOTAXIME SODIUM
- CEFOTETAN DISODIUM
- CEFOXITIN SODIUM
- CEFTAROLINE FOSAMIL

CEFTAZIDIME

CEFTAZIDIME/AVIBACTAM

CEFTOLOZANE/TAZOBACTAM

CEFTRIAXONE SODIUM

CEFUROXIME SODIUM

CEMIPLIMAB-rwlc

CENTRUROIDES (SCORPION) IMMUNE F(ab')$_2$ (EQUINE) INJECTION

CETIRIZINE HYDROCHLORIDE

CETUXIMAB

CHLORAMPHENICOL SODIUM SUCCINATE

CHLOROTHIAZIDE SODIUM

CHLORPROMAZINE HYDROCHLORIDE

CIDOFOVIR INJECTION

CIPROFLOXACIN

CISATRACURIUM BESYLATE

CISPLATIN

CLADRIBINE

CLEVIDIPINE BUTYRATE

CLINDAMYCIN PHOSPHATE

CLOFARABINE

COAGULATION FACTOR VIIa (RECOMBINANT) RTS

COAGULATION FACTOR X (HUMAN)

COAGULATION FACTOR Xa (RECOMBINANT), INACTIVATED-zhzo

COLISTIMETHATE SODIUM

CONIVAPTAN HYDROCHLORIDE

CONJUGATED ESTROGENS

COPANLISIB

CORTICORELIN OVINE TRIFLUTATE

COSYNTROPIN

CRIZANLIZUMAB-tmca INJECTION

CROTALIDAE IMMUNE $F(ab')_2$ (EQUINE)

CYCLOPHOSPHAMIDE

CYCLOSPORINE

CYSTEINE HYDROCHLORIDE

CYTARABINE

CYTOMEGALOVIRUS IMMUNE GLOBULIN INTRAVENOUS (HUMAN)*

Generic drugs: D

D

DACARBAZINE

DACTINOMYCIN

DALBAVANCIN

DANTROLENE SODIUM

DAPTOMYCIN

DARATUMUMAB

DARBEPOETIN ALFA

DAUNORUBICIN AND CYTARABINE LIPOSOME FOR INJECTION

DAUNORUBICIN HYDROCHLORIDE ■ DAUNORUBICIN CITRATE LIPOSOMAL INJECTION

DECITABINE FOR INJECTION

DEFEROXAMINE MESYLATE

DEFIBROTIDE

DELAFLOXACIN

DENILEUKIN DIFTITOX

DESMOPRESSIN ACETATE

DEXAMETHASONE SODIUM PHOSPHATE

DEXMEDETOMIDINE HYDROCHLORIDE

DEXRAZOXANE

DEXTRAN 1

DEXTRAN HIGH MOLECULAR WEIGHT

DEXTRAN LOW MOLECULAR WEIGHT

DEXTROSE

DIAZEPAM

DIAZOXIDE

Difelikefalin

DIGOXIN

DIGOXIN IMMUNE FAB (OVINE)

DIHYDROERGOTAMINE MESYLATE

DILTIAZEM HYDROCHLORIDE

DIMENHYDRINATE

DINUTUXIMAB

DIPHENHYDRAMINE HYDROCHLORIDE

DIPHTHERIA ANTITOXIN

DIPYRIDAMOLE

DOBUTAMINE HYDROCHLORIDE

DOCETAXEL

- DOLASETRON MESYLATE
- DOPAMINE HYDROCHLORIDE
- DOXAPRAM HYDROCHLORIDE
- DOXERCALCIFEROL
- DOXORUBICIN HYDROCHLORIDE ■ DOXORUBICIN HYDROCHLORIDE LIPOSOMAL INJECTION
- DOXYCYCLINE HYCLATE
- DROPERIDOL
- DURVALUMAB

Generic drugs: E

E

- ECULIZUMAB
- EDARAVONE
- EDETATE CALCIUM DISODIUM
- EDETATE DISODIUM
- EFGARTIGIMOD ALFA
- ELOSULFASE ALFA
- ELOTUZUMAB
- EMAPALUMAB-lzsg
- ENALAPRILAT
- ENFORTUMAB VEDOTIN-ejfv
- EPHEDRINE SULFATE
- EPINEPHRINE HYDROCHLORIDE
- EPIRUBICIN HYDROCHLORIDE
- EPOETIN ALFA ■ EPOETIN ALFA-epbx
- EPOPROSTENOL SODIUM

- EPTIFIBATIDE
- EPTINEZUMAB-jjmr
- ERAVACYCLINE
- ERIBULIN MESYLATE
- ERTAPENEM
- ERYTHROMYCIN LACTOBIONATE
- ESMOLOL HYDROCHLORIDE
- ESOMEPRAZOLE SODIUM
- ETELCALCETIDE
- ETEPLIRSEN
- ETHACRYNIC ACID
- ETOMIDATE
- ETOPOSIDE

Generic drugs: F

F

- FACTOR IX (HUMAN) ■ FACTOR IX COMPLEX (HUMAN)
- FACTOR IX (RECOMBINANT)
- FACTOR XIII CONCENTRATE (HUMAN)
- FAMOTIDINE
- FAM-TRASTUZUMAB DERUXTECAN-nxki
- FAT EMULSION, INTRAVENOUS
- FENOLDOPAM MESYLATE
- FENTANYL CITRATE
- FERRIC CARBOXYMALTOSE INJECTION
- FERUMOXYTOL

- FIBRINOGEN CONCENTRATE (HUMAN)
- FILGRASTIM ■ FILGRASTIM-aafi ■ FILGRASTIM-sndz
- FISH OIL TRIGLYCERIDES INJECTABLE EMULSION
- FLUCONAZOLE
- FLUDARABINE PHOSPHATE
- FLUMAZENIL
- FLUOROURACIL
- FOLIC ACID
- FOMEPIZOLE INJECTION
- FOSAPREPITANT DIMEGLUMINE
- FOSCARNET SODIUM
- FOSNETUPITANT AND PALONOSETRON
- FOSPHENYTOIN SODIUM
- FOSPROPOFOL DISODIUM
- FUROSEMIDE

Generic drugs: G

G

- GANCICLOVIR SODIUM
- GALLIUM NITRATE
- GALSULFASE
- GEMCITABINE HYDROCHLORIDE
- GENTAMICIN SULFATE
- GLUCAGON
- GLUCARPIDASE
- GLYCOPYRROLATE

- GOLIMUMAB
- GOLODIRSEN INJECTION
- GRANISETRON HYDROCHLORIDE

Generic drugs: H

H

- HEMIN
- HEPARIN SODIUM
- HEPATITIS B IMMUNE GLOBULIN INTRAVENOUS (HUMAN)
- HETASTARCH
- HYDRALAZINE HYDROCHLORIDE
- HYDROCORTISONE SODIUM SUCCINATE
- HYDROMORPHONE HYDROCHLORIDE
- HYDROXOCOBALAMIN
- 6% HYDROXYETHYL STARCH 130/0.4 IN 0.9% SODIUM CHLORIDE INJECTION

Generic drugs: I

I

- IBALIZUMAB-uiyk
- IBANDRONATE SODIUM
- IBUPROFEN
- IBUPROFEN LYSINE
- IBUTILIDE FUMARATE
- IDARUBICIN HYDROCHLORIDE
- IDARUCIZUMAB
- IDURSULFASE
- IFOSFAMIDE

IMIGLUCERASE ■ VELAGLUCERASE ALFA

IMIPENEM-CILASTATIN

IMIPENEM, CILASTATIN, AND RELEBACTAM

IMMUNE GLOBULIN INTRAVENOUS

INAMRINONE LACTATE

INDOMETHACIN SODIUM

INFLIXIMAB ■ INFLIXIMAB-dyyb ■ INFLIXIMAB-abda ■ INFLIXIMAB-axxq ■ INFLIXIMAB-qbtx

INOTUZUMAB OZOGAMICIN

INSULIN HUMAN INJECTION (REGULAR)

INTERFERON ALFA-2b, RECOMBINANT

IPILIMUMAB

IRINOTECAN HYDROCHLORIDE ■ IRINOTECAN LIPOSOME INJECTION

IRON DEXTRAN INJECTION

IRON SUCROSE

ISATUXIMAB

ISAVUCONAZONIUM SULFATE

ISOPROTERENOL HYDROCHLORIDE

IXABEPILONE

Generic drugs: K

K

KETOROLAC TROMETHAMINE

KANAMYCIN SULFATE

Generic drugs: L

L

LABETALOL HYDROCHLORIDE

- LACOSAMIDE
- LARONIDASE
- LEFAMULIN
- LETERMOVIR
- LEUCOVORIN CALCIUM
- LEVETIRACETAM INJECTION
- LEVOCARNITINE
- LEVOFLOXACIN
- LEVOLEUCOVORIN
- LEVOTHYROXINE SODIUM
- LIDOCAINE HYDROCHLORIDE
- LINCOMYCIN HYDROCHLORIDE
- LINEZOLID
- LIOTHYRONINE SODIUM
- LORAZEPAM
- LURBINECTEDIN
- LYMPHOCYTE IMMUNE GLOBULIN

Generic drugs: M

M

- MAGNESIUM SULFATE
- MANNITOL
- MECHLORETHAMINE HYDROCHLORIDE
- MELOXICAM INJECTION
- MEPERIDINE HYDROCHLORIDE
- MEROPENEM

MEROPENEM AND VABORBACTAM FOR INJECTION

MESNA

METHADONE HYDROCHLORIDE

METHOCARBAMOL

METHOTREXATE SODIUM

METHOXY POLYETHYLENE GLYCOL-EPOETIN BETA

METHYLENE BLUE

METHYLERGONOVINE MALEATE

METHYLPREDNISOLONE SODIUM SUCCINATE

METOCLOPRAMIDE HYDROCHLORIDE

METOPROLOL TARTRATE

METRONIDAZOLE HYDROCHLORIDE

MICAFUNGIN SODIUM

MIDAZOLAM HYDROCHLORIDE

MILRINONE LACTATE

MINOCYCLINE HYDROCHLORIDE

MITOMYCIN

MITOXANTRONE HYDROCHLORIDE

MOGAMULIZUMAB-kpkc

MORPHINE SULFATE

MOXIFLOXACIN HYDROCHLORIDE

MULTIVITAMIN INFUSION

MYCOPHENOLATE MOFETIL HYDROCHLORIDE

Generic drugs: N

N

- NAFCILLIN SODIUM
- NALBUPHINE HYDROCHLORIDE
- NALOXONE HYDROCHLORIDE
- NATALIZUMAB
- NECITUMUMAB
- NELARABINE
- NEOSTIGMINE METHYLSULFATE
- NICARDIPINE HYDROCHLORIDE
- NITROGLYCERIN IV
- NITROPRUSSIDE SODIUM
- NIVOLUMAB
- NIVOLUMAB AND RELATLIMAB
- NOREPINEPHRINE BITARTRATE

Generic drugs: O

O

- OBINUTUZUMAB
- OBILTOXAXIMAB
- OCRELIZUMAB
- OCTREOTIDE ACETATE
- OFATUMUMAB
- OLARATUMAB
- OMADACYCLINE
- ONASEMNOGENE ABEPARVOVEC-xioi
- ONDANSETRON HYDROCHLORIDE
- ORITAVANCIN

ORPHENADRINE CITRATE

OXACILLIN SODIUM

OXALIPLATIN

OXYTOCIN INJECTION

Generic drugs: P

P

PACLITAXEL ■ PACLITAXEL PROTEIN-BOUND PARTICLES FOR INJECTABLE SUSPENSION (ALBUMIN-BOUND)

PALIFERMIN

PALONOSETRON

PAMIDRONATE DISODIUM

PANCURONIUM BROMIDE

PANITUMUMAB

PANTOPRAZOLE SODIUM

PAPAVERINE HYDROCHLORIDE

PARICALCITOL

PATISIRAN

PEGASPARGASE ■ ASPARAGINASE *Erwinia chrysanthemi*

PEGLOTICASE

PEMBROLIZUMAB

PEMETREXED

PENICILLIN G AQUEOUS

PENTAMIDINE ISETHIONATE

PENTETATE CALCIUM TRISODIUM INJECTION ■ PENTETATE ZINC TRISODIUM INJECTION

PENTOBARBITAL SODIUM

PENTOSTATIN

PERAMIVIR

PERTUZUMAB

PHENOBARBITAL SODIUM

PHENTOLAMINE MESYLATE

PHENYLEPHRINE HYDROCHLORIDE

PHENYTOIN SODIUM

PHOSPHATE

PHYSOSTIGMINE SALICYLATE

PHYTONADIONE

PIPERACILLIN SODIUM

PIPERACILLIN SODIUM AND TAZOBACTAM SODIUM

PLASMA PROTEIN FRACTION

PLAZOMICIN

POLATUZUMAB VEDOTIN-piiq

POOLED PLASMA (HUMAN)

PORFIMER SODIUM

POSACONAZOLE

POTASSIUM ACETATE AND POTASSIUM CHLORIDE

PRALATREXATE

PRALIDOXIME CHLORIDE

PROCAINAMIDE HYDROCHLORIDE

PROCHLORPERAZINE EDISYLATE

PROMETHAZINE HYDROCHLORIDE

PROPOFOL INJECTION

- PROPRANOLOL HYDROCHLORIDE
- PROTAMINE SULFATE
- PROTEIN AMINO ACIDS, DEXTROSE, FAT EMULSION, AND ELECTROLYTES
- PROTEIN (AMINO ACID) PRODUCTS
- PROTEIN C CONCENTRATE (HUMAN)
- PROTHROMBIN COMPLEX CONCENTRATE (HUMAN)
- PYRIDOSTIGMINE BROMIDE
- PYRIDOXINE HYDROCHLORIDE

Generic drugs: R

R

- RASBURICASE
- RAVULIZUMAB-cwvz
- RAXIBACUMAB
- REGADENOSON
- REMDESIVIR
- REMIFENTANIL HYDROCHLORIDE
- RESLIZUMAB
- RETEPLASE RECOMBINANT
- Rho(D) IMMUNE GLOBULIN INTRAVENOUS (HUMAN)
- RIFAMPIN
- RITUXIMAB ■ RITUXIMAB-abbs ■ RITUXIMAB-pvvr ■ RITUXIMAB-arrx
- ROCURONIUM BROMIDE
- ROMIDEPSIN

Generic drugs: S

S

SACITUZUMAB GOVITECAN

SARGRAMOSTIM

SEBELIPASE ALFA

SECRETIN (HUMAN) ■ SECRETIN (PORCINE)

SERMORELIN ACETATE

SILDENAFIL*

SILTUXIMAB

SINCALIDE

SIPULEUCEL-T

SODIUM ACETATE

SODIUM BICARBONATE

SODIUM CHLORIDE

SODIUM FERRIC GLUCONATE COMPLEX

SODIUM THIOSULFATE

SODIUM LACTATE

SODIUM NITRITE AND SODIUM THIOSULFATE

SODIUM PHENYLACETATE AND SODIUM BENZOATE

SOTALOL HYDROCHLORIDE

SPESOLIMAB

STREPTOKINASE

STREPTOMYCIN SULFATE

STREPTOZOCIN

SUCCINYLCHOLINE CHLORIDE

SUGAMMADEX

SULFAMETHOXAZOLE AND TRIMETHOPRIM

Generic drugs: T

T

- TACROLIMUS
- TAGRAXOFUSP-erzs
- TALIGLUCERASE ALFA
- TEDIZOLID PHOSPHATE
- TELAVANCIN
- TEMOZOLOMIDE
- TEMSIROLIMUS
- TENECTEPLASE
- TENIPOSIDE
- TEPROTUMUMAB-trbw
- THEOPHYLLINE IN D5W
- TERLIPRESSIN
- THIAMINE HYDROCHLORIDE
- THIOTEPA
- TICARCILLIN DISODIUM AND CLAVULANATE POTASSIUM
- TIGECYCLINE FOR INJECTION
- TIROFIBAN HYDROCHLORIDE
- TISAGENLECLEUCEL
- TOBRAMYCIN SULFATE
- TOCILIZUMAB
- TOPOTECAN HYDROCHLORIDE
- TRABECTEDIN
- TRACE METALS

TRANEXAMIC ACID

TRASTUZUMAB ■ TRASTUZUMAB-dkst ■ TRASTUZUMAB-dttb ■ TRASTUZUMAB-pkrb ■ TRASTUZUMAB-anns ■ TRASTUZUMAB-qyyp

TREPROSTINIL

TRILACICLIB

Generic drugs: V

V

VALPROATE SODIUM

VACCINIA IMMUNE GLOBULIN INTRAVENOUS (HUMAN)

VANCOMYCIN HYDROCHLORIDE

VASOPRESSIN INJECTION

VECURONIUM BROMIDE

VEDOLIZUMAB

VERAPAMIL HYDROCHLORIDE

VERTEPORFIN

VESTRONIDASE ALFA-vjbk INJECTION

VINBLASTINE SULFATE

VINCRISTINE SULFATE ■ VINCRISTINE SULFATE LIPOSOME INJECTION

VINORELBINE

VON WILLEBRAND FACTOR/COAGULATION FACTOR VIII COMPLEX (HUMAN)

VON WILLEBRAND FACTOR (RECOMBINANT)

VORICONAZOLE

Generic drugs: Z

Z

ZIDOVUDINE

ZIV-AFLIBERCEPT

ZOLEDRONIC ACID

Appendix A: Recommendations for the Safe Use and Handling of Cytotoxic Drugs

Appendix B: FDA Pregnancy Categories

Appendix C: U.S. Department of Health and Human Services, National Institutes of Health, National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE)

Appendix D: Information for Patients Receiving Immunosuppressive Agents

Appendix E: Recently Approved Drugs

INDEX

Solution compatibility chart

Selected Agents Not Included in the Book, *Evolve website*

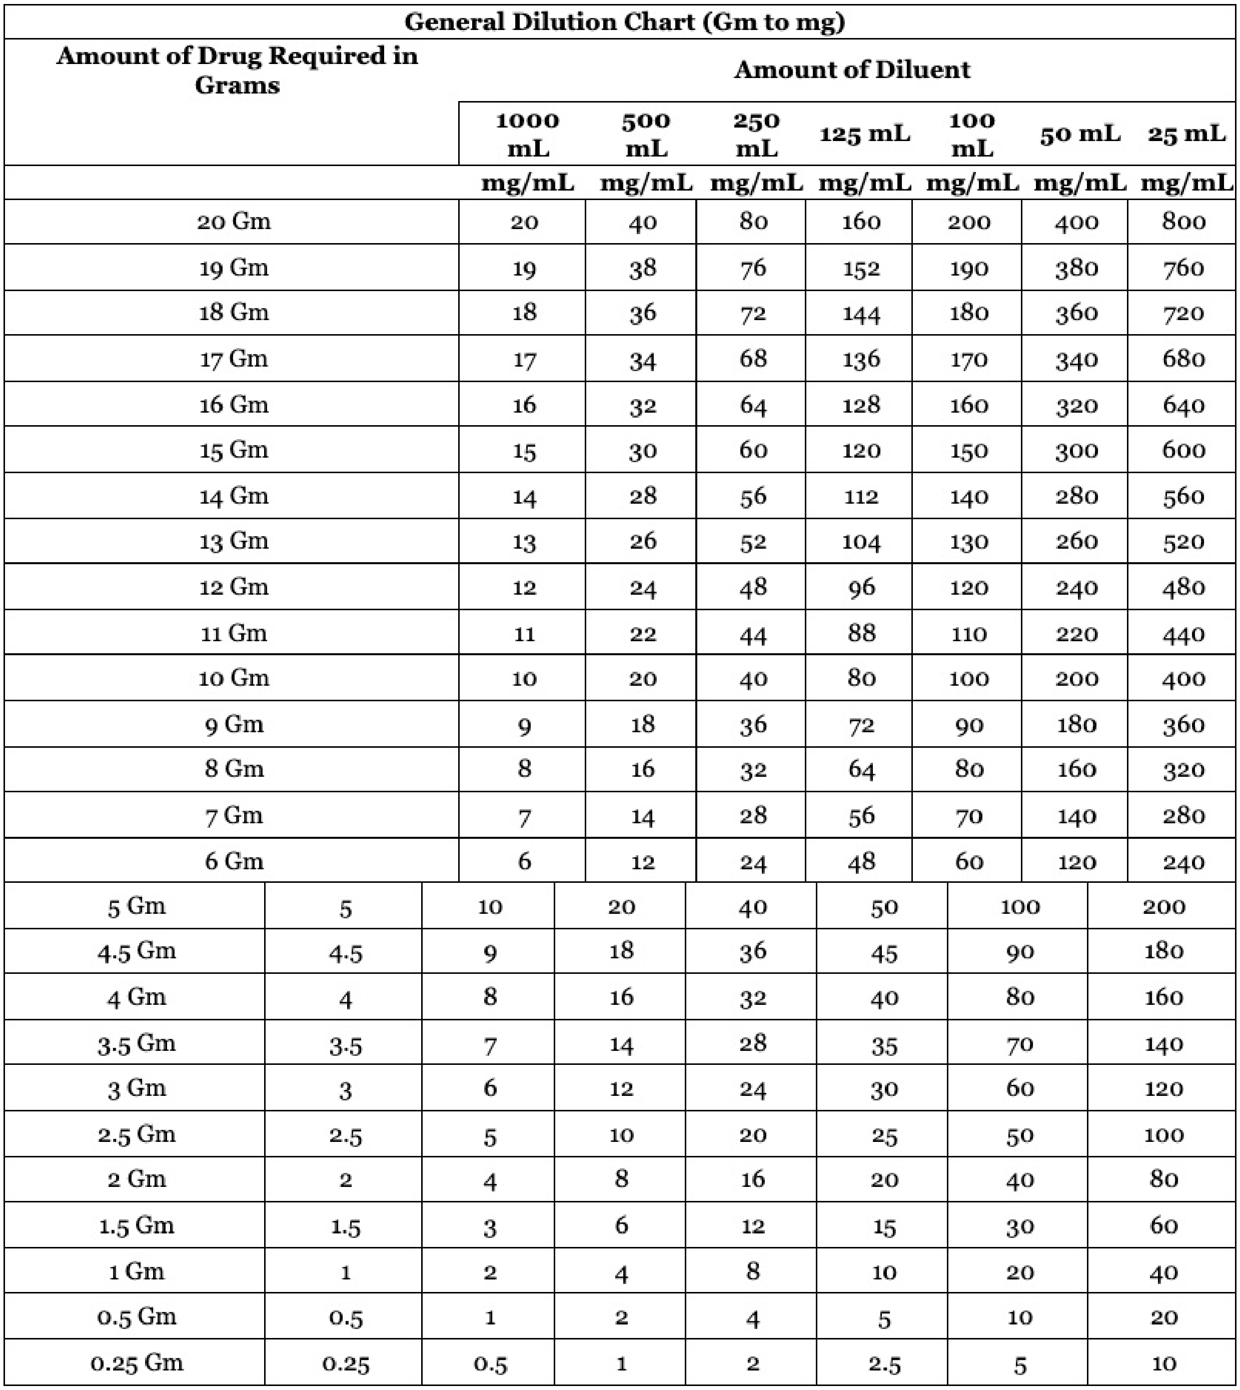
Ado-Trastuzumab
Agalsidase Beta
Alfentanil Hydrochloride
Alglucerase
Alglucosidase Alfa
Alpha$_1$-Proteinase Inhibitor (Human)
Amifostine
Ammonium Chloride
Amobarbital Sodium
Anthrax Immune Globulin Intravenous (Human)
Antivenin (*Latrodectus mactans*)
Antivenin (*Micrurus fulvius*)
Antivenin Crotalidae Polyvalent Immune Fab (Ovine)
Arginine Hydrochloride
Ascorbic Acid
Asparaginase *Erwinia chrysanthemi*
Atracurium Besylate
Axicabtagene Ciloleucel
Azathioprine Sodium
Blinatumomab
Botulism Immune Globulin (Intravenous Human)
Brentuximab
Busulfan
Caffeine and Sodium Benzoate
Capreomycin
Carfilzomib

Centruroides (Scorpion) Immune $F(ab')_2$ (Equine) Injection
Chloramphenicol Sodium Succinate
Conjugated Estrogens
Copanlisib
Corticorelin Ovine Triflutate
Crizanlizumab-tmca
Crotalidae Immune $F(ab')_2$ (Equine)
Dactinomycin
Daratumumab
Deferoxamine Mesylate
Defibrotide
Denileukin Diftitox
Dextran
Diazoxide
Dimenhydrinate
Diphtheria Antitoxin
Dolasetron Mesylate
Doxapram Hydrochloride
Droperidol
Edetate Calcium Disodium
Edetate Disodium
Elosulfase Alfa
Elotuzumab
Enfortumab Vedotin-ejfv
Ethacrynic Acid
Fam-Trastuzumab Deruxtecan-nxki
Fospropofol Disodium
Gallium Nitrate
Galsulfase
6% Hydroxyethyl Starch 130/0.4 in NS
Idursulfase
Imiglucerase/Velaglucerase Alfa
Inamrinone Lactate
Inotuzumab Ozogamicin
Interferon Alfa-2b, Recombinant
Ipilimumab
Kanamycin Sulfate
Laronidase
Levocarnitine
Lincomycin Hydrochloride
Liothyronine Sodium
Mechlorethamine Hydrochloride
Melphalan
Meperidine Hydrochloride
Methadone
Methoxy Polyethylene Glycol-Epoetin Beta

Methylene Blue
Minocycline Hydrochloride
Mogamulizumab-kpkc
Moxetumomab
Mylotarg
Obiltoxaximab
Orphenadrine Citrate
Oxacillin Sodium
Pancuronium Bromide
Pegaspargase
Pentazocine (Lactate)
Pentetate Calcium Trisodium/Pentetate Zinc Trisodium
Phentolamine Mesylate
Piperacillin Sodium
Plasma Protein Fraction
Pooled Plasma (Human)
Pralidoxime Chloride
Protein (Amino Acid) Products
Protein C Concentrate (Human)
Pyridostigmine Bromide
Pyridoxine (Vitamin B_6)
Quinidine Gluconate Injection
Raxibacumab
Regadenoson
Remifentanil Hydrochloride
Rocuronium Bromide
Ramucirumab
Sebelipase Alfa
Secretin
Sermorelin Acetate
Siltuximab
Sincalide
Sipuleucel-T
Sodium Lactate
Sodium Nitrite and Sodium Thiosulfate
Sodium Phenylacetate and Sodium Benzoate
Streptokinase
Streptomycin Sulfate
Streptozocin
Succinylcholine Chloride
Taliglucerase Alfa
Theophylline in D5W
Ticarcillin Disodium and Clavulanate Potassium
Tisagenlecleucel
Trabectedin
Trace Metals

Tretten
Treprostinil
Vaccinia Immune Globulin Intravenous (Human)
Verteporfin
Vestronidase Alfa-vjbk Injection
Ziv-Aflibercept

General Dilution Chart



General Dilution Chart (Gm to mg)							
Amount of Drug Required in Grams	**Amount of Diluent**						
	1000 mL	**500 mL**	**250 mL**	**125 mL**	**100 mL**	**50 mL**	**25 mL**
	mg/mL	**mg/mL**	**mg/mL**	**mg/mL**	**mg/mL**	**mg/mL**	**mg/mL**
20 Gm	20	40	80	160	200	400	800
19 Gm	19	38	76	152	190	380	760
18 Gm	18	36	72	144	180	360	720
17 Gm	17	34	68	136	170	340	680
16 Gm	16	32	64	128	160	320	640
15 Gm	15	30	60	120	150	300	600
14 Gm	14	28	56	112	140	280	560
13 Gm	13	26	52	104	130	260	520
12 Gm	12	24	48	96	120	240	480
11 Gm	11	22	44	88	110	220	440
10 Gm	10	20	40	80	100	200	400
9 Gm	9	18	36	72	90	180	360
8 Gm	8	16	32	64	80	160	320
7 Gm	7	14	28	56	70	140	280
6 Gm	6	12	24	48	60	120	240
5 Gm	5	10	20	40	50	100	200
4.5 Gm	4.5	9	18	36	45	90	180
4 Gm	4	8	16	32	40	80	160
3.5 Gm	3.5	7	14	28	35	70	140
3 Gm	3	6	12	24	30	60	120
2.5 Gm	2.5	5	10	20	25	50	100
2 Gm	2	4	8	16	20	40	80
1.5 Gm	1.5	3	6	12	15	30	60
1 Gm	1	2	4	8	10	20	40
0.5 Gm	0.5	1	2	4	5	10	20
0.25 Gm	0.25	0.5	1	2	2.5	5	10

To use chart:

1. Find mg/mL desired, and track to the amount of diluent desired and amount of drug in Gm required.
2. Find the amount of drug in Gm required, and track to the diluent desired and/or mg/mL desired.
3. Find the amount of diluent required, and track to the amount of drug in Gm and/or mg/mL desired.

Formula: Substitute any number for *x*

x Gm diluted in 1000 mL = x mg/mL (1 Gm in 1000 mL = 1 mg/mL)
x Gm diluted in 500 mL = $2x$ mg/mL (1 Gm in 500 mL = 2 mg/mL)
x Gm diluted in 250 mL = $4x$ mg/mL (1 Gm in 250 mL = 4 mg/mL)
x Gm diluted in 125 mL = $8x$ mg/mL (1 Gm in 125 mL = 8 mg/mL)
x Gm diluted in 100 mL = $10x$ mg/mL (1 Gm in 100 mL = 10 mg/mL)
x Gm diluted in 50 mL = $20x$ mg/mL (1 Gm in 50 mL = 20 mg/mL)
x Gm diluted in 25 mL = $40x$ mg/mL (1 Gm in 25 mL = 40 mg/mL)

Some variation occurs from the manufacturer’s overfill or if the drug is in liquid form. If absolute accuracy is required, these variations can be avoided by withdrawing an amount in mL from the diluent equal to the manufacturer’s overfill and/or an amount equal to the amount in mL of the drug. Consult the pharmacist for specific information on the manufacturer’s overfill of infusion fluids used in your facility.

General Dilution Chart (mg to mcg)							
Amount of Drug Required in Milligrams	Amount of Diluent						
	1000 mL	500 mL	250 mL	125 mL	100 mL	50 mL	25 mL
	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL	mcg/mL
20 mg	20	40	80	160	200	400	800
19 mg	19	38	76	152	190	380	760

8 mg	8	16	32	64	80	160	320
7 mg	7	14	28	56	70	140	280
6 mg	6	12	24	48	60	120	240
5 mg	5	10	20	40	50	100	200
4.5 mg	4.5	9	18	36	45	90	180
4 mg	4	8	16	32	40	80	160
3.5 mg	3.5	7	14	28	35	70	140
3 mg	3	6	12	24	30	60	120
2.5 mg	2.5	5	10	20	25	50	100
2 mg	2	4	8	16	20	40	80
1.5 mg	1.5	3	6	12	15	30	60
1 mg	1	2	4	8	10	20	40
0.5 mg	0.5	1	2	4	5	10	20
0.25 mg	0.25	0.5	1	2	2.5	5	10

To use chart:

1. Find the mcg/mL desired, and track to the amount of diluent desired and the amount of drug in mg required.
2. Find the amount of drug in mg required, and track to diluent desired and/or mcg/mL desired.
3. Find the amount of diluent required, and track to the amount of drug in mg and/or mcg/mL desired.

Formula: Substitute any number for x

x mg diluted in 1000 mL = x mcg/mL (1 mg in 1000 mL = 1 mcg/mL)
x mg diluted in 500 mL = $2x$ mcg/mL (1 mg in 500 mL = 2 mcg/mL)
x mg diluted in 250 mL = $4x$ mcg/mL (1 mg in 250 mL = 4 mcg/mL)
x mg diluted in 125 mL = $8x$ mcg/mL (1 mg in 125 mL = 8 mcg/mL)
x mg diluted in 100 mL = $10x$ mcg/mL (1 mg in 100 mL = 10 mcg/mL)
x mg diluted in 50 mL = $20x$ mcg/mL (1 mg in 50 mL = 20 mcg/mL)
x mg diluted in 25 mL = $40x$ mcg/mL (1 mg in 25 mL = 40 mcg/mL)

Some variation occurs from the manufacturer’s overfill or if the drug is in liquid form. If absolute accuracy is required, these variations can be avoided by withdrawing an amount in mL from the diluent equal to manufacturer’s overfill and/or an amount equal to the amount in mL of the drug. Consult the pharmacist for specific information on the manufacturer’s overfill of infusion fluids used in your facility.

How to Use This Book

STEP 1

Refer to the index at the back of the book. You can find any drug by any name in less than 5 seconds. All drugs are cross-indexed by generic and all known trade names. The index is easily distinguished by a printed blue bar at the edge of the pages. Drugs are also indexed by pharmacologic action. With one turn of the page, all drugs included in the text with similar pharmacologic actions and their page numbers are available to you. Everything is strictly alphabetized; you will never be required to refer to additional pages to locate a drug.

STEP 2

Turn to the single page number given after the name of the drug. All information about the drug is included as continuous reading. You will rarely be required to turn to another section of the book to be completely informed. Specific breakdowns of each drug (Usual Dose, Pediatric Dose, Dose Adjustments, Dilution, Compatibility, Rate of Administration, Actions, Indications and Uses, Precautions, Contraindications, Drug/Lab Interactions, Side Effects, and Antidote) are consistent in format and printed in boldface type. Subheadings under these categories are in boldface. Scan quickly for Usual Dose, Dose Adjustments, Drug/Lab Interactions, Side Effects, or Antidote or carefully read all included information. The choice is yours. A quick scan will take 5 to 10 seconds. Even the most complicated drugs will take less than 2 minutes to read completely. Read each monograph carefully and completely before administering a drug to a specific patient for the first time, and review it any time a new drug is added to the patient's drug profile.

That's it!

This is a fast, complete, and accurate reference for anyone administering intravenous medications. The spiral binding is specifically designed to lie flat, leaving your hands free to secure needed supplies, prepare your medication, or even ventilate a patient while you read the needed information.

Develop the "look it up" habit.

Clear, concise language and simplicity of form contribute to quick, easy use of this handbook. Before your first use, read the Preface, as it contains lots of helpful information. Check out the *Intravenous Medications* website for monographs no longer included in this text and for other useful IV medication information: **http://evolve.elsevier.com/IVMeds**

Dedication

To my daughter,
Kristin Collins,
thank you for being such a joy.
I am so proud of the woman you have become.

To my father,
Charles Rainforth,
thank you for being the best dad
a girl could ever ask for.

Preface

This Year 2024 edition marks the 51st year of publication of *Intravenous Medications*. All previous editions are considered out of date. We would like to welcome the expert contributions from the National Coalition for IV Push Safety in this new edition.

Intravenous Medications is designed for use anywhere intravenous medications are prepared and administered, such as in critical care areas, at the nursing station, in the office, in public health and home care settings, and by students and members of the armed services. Pertinent information can be found in a few seconds. Take advantage of its availability and quickly review every intravenous medication before administration.

When a medication is prescribed, the nurse must evaluate it for appropriateness and may need to prepare it, administer it, and observe the effects. If, after reviewing the information in *Intravenous Medications*, you have any questions about any order you are given, clarify it with the physician, consult the pharmacist, or consult your supervisor. The circumstances will determine whom you will approach first. If the physician thinks it is imperative to carry out an order even though you have unanswered questions, never hesitate to request that the physician administer the medication instead of you. In this era of constant change, the physician should be willing to provide you, your supervisor, and/or the pharmacist with current studies documenting the validity and appropriateness of orders.

All information presented in this handbook pertains only to the intravenous use of the drug and not necessarily to intramuscular, subcutaneous, oral, or other means of administration.

In this 40th edition, a total of ten new drugs approved by the FDA for intravenous use have been incorporated.

The new drugs include **isatuximab** for multiple myeloma; **lurbinectedin** for metastatic small-cell lung cancer; **sacituzumab govitecan** for breast or urothelial cancer; **trilaciclib** for chemotherapy-induced myelosuppression; **etesevimab** for COVID-19 treatment under emergency use authorization (with bamlanivimab); **efgartigimod alfa** for myasthenia gravis; **casimersen** for Duchenne muscular dystrophy; **aducanumab** for Alzheimer’s disease; **avalglucosidase alfa** for Pompe disease; and **anifrolumab** for systemic lupus erythematosus.

In addition, ado-trastuzumab, busulfan, carfilzomib, crizanlizumab-tmca, daratumumab, droperidol, elotuzumab, and ipilimumab have been moved from the text to the Evolve website.

Several of the drugs in this text and on the Evolve website are biosimilars. Biosimilars are biological products that are licensed (approved) by the FDA because they are highly similar to an already FDA-approved biological product (known as the reference product (known as the reference product, such as trastuzumab [Herceptin]) but have allowable differences because they are made from living organisms. Biosimilars also have no clinically meaningful differences in terms of safety, purity, and potency from the reference product.

Many new uses have been approved for established drugs, and numerous safety issues have been identified by the FDA. All of these changes are incorporated so that our readers have the most current information available.

We continually strive to make the information in this handbook informative and easy to access. **We continue to identify drugs with a Black Box Warning BBW in the main heading of the monograph.** In addition, **Black Box Warning statements are shaded** in light gray, **and a different typeface is used** for instant identification wherever they appear in the text. ***Blue-screened text*** emphasizes a special circumstance not covered by a Black Box Warning. The FDA is now identifying **Limitations of Use** of drugs under Indications. Previously this information had been placed in Precautions. Common Toxicity Criteria (CTC) are available at https://ctep.cancer.gov/protocoldevelopment/electronic_applications/ctc.htm.

The Joint Commission and the **Institute for Safe Medication Practices (ISMP)** have strongly emphasized various ways to reduce errors in drug ordering and administration. ***Intravenous Medications*** uses both generic and trade names and spells out all symbols (except in charts where space is limited). The symbols are included in the Key to Abbreviations (p. xvii) if you need a refresher.

The Joint Commission, the ISMP, the American Pharmaceutical Association, and several other organizations have identified "High-Alert Medications" (a list of medications with the highest risk of injury when misused). The websites of these organizations contain considerable information and identify common risk factors and suggested strategies to reduce the risk of errors. All IV medications are considered high risk because they have an immediate effect, are irretrievable, and can cause life-threatening side effects with incorrect usage. We advise the readers to consider several important sources for intravenous medication safety such the National Coalition for IV Push Safety, the Infusion Nurses Society, and the Institute for Safe Medication Practices.

Elsevier offers electronic versions of *Intravenous Medications* for handheld devices, tablets, laptops, and desktop computers. These electronic versions are convenient and portable alternatives or supplements to the printed book. In addition, all drugs currently on the Evolve IV Meds website **(http://evolve.elsevier.com/IVMeds)** for *Intravenous Medications* (because of space limitations for the print version) are **now all** incorporated in these electronic versions in alphabetical order to give you a complete package. Although the electronic versions are accessible wherever you have an electronic device, keep in mind that on some devices the entire monograph may not be visible at the same time. It is the user's responsibility to be familiar with the complete monograph and ***all*** aspects of each drug before administration.

Health care today is an intense environment. The speed of change is overwhelming, but the authors and publisher of *Intravenous Medications* have a commitment to provide all healthcare professionals who have the responsibility to administer IV medications with annual editions that incorporate complete, accurate, and current information in a clear, concise, accessible, and reliable tool. FDA websites are monitored throughout the year and provide many important updates, such as dose changes, new pediatric doses, additional disease-specific doses, refinements in dosing applications, new indications, new drug interactions, additional precautions, updates on post-marketing side effects, and new information on antidotes. Most drugs currently approved for intravenous use are included in the print version or are on the Evolve website: **http://evolve.elsevier.com/IVMeds/**. (See pp. xiv and xv for a listing.) Helpful charts for dilution and/or rate of administration are incorporated in selected monographs. A General Dilution Chart to simplify calculations is found on the inside front cover. Front matter material provides a Key to Abbreviations and Important IV Therapy Facts.

Appreciation is extended to Sonya Seigafuse, Danielle M. Frazier, and Jodi M. Willard at Elsevier and to Joe Rekart at Graphic World.

And a thank you to the users of this reference. By seeking out this information, you serve your patients' needs and contribute to the safe administration of intravenous medications.

Format and Content of *Intravenous Medications*

Designed to facilitate quick reference, each entry begins with the generic name of the drug in boldface type. **Medications with a Black Box Warning are identified with a symbol BBW in the main heading**. Phonetic pronunciations appear just below the generic name. Drug categories follow. The primary category may be followed by additional ones representing the multiple uses of a medication. Associated trade names are under the generic name. Boldface type and alphabetical order enable the reader to verify correct drug names easily. The use of a Canadian maple leaf symbol (🍁) after a trade name indicates availability in Canada only.

Headings within drug monographs are as follows.

USUAL ADULT DOSE:

Doses recommended are the usual range for adults unless specifically stated otherwise. This information is presented first to enable the nurse to verify that the medication order is within acceptable parameters while checking the order and before preparation.

Pretreatment:

This subheading section alerts you to situations that must or should be completed before administering the medication. Many of the newer medications can cause fetal harm, so you will find the statement "Verify pregnancy status" here. You will also be alerted to premedication, baseline studies, pretesting, immunization, pre-hydration, and other requirements indicated before treatment and will be referred to the place in the monograph containing needed additional information.

PEDIATRIC DOSE:

Pediatric doses are specifically stated when different from the adult dose. Not all medications are labeled for use in pediatric patients, and off-label use is common. See Maternal/Child for information on safety and effectiveness for use in pediatric patients. A ready-to-administer product should be used with caution if only administering a partial dose to prevent unintentional overdose.

INFANT AND/OR NEONATAL DOSE:

This information is included if available and distinct from Pediatric Dose. See Maternal/Child for information on safety and effectiveness for use in pediatric patients, including infants and neonates. Medications for pediatric patients would likely be supplied by the pharmacy in a syringe or syringe pump administration or retrograde injection.

ALL AGE DOSE ADJUSTMENTS:

Any situation that requires increasing or decreasing a dose is mentioned here. The range covers adjustments needed for elderly, debilitated, or hepatic or renal impairment patients; adjustments required by race or gender; or adjustments required in the presence of other medications or as physical conditions are monitored.

DILUTION:

Medications given IV push may be available in ampules, vials, manufactured prefilled syringes, compounded prefilled syringes, and ready-to-assemble products such as Carpuject™. It is important to note that routine dilution of IV push medications is contraindicated unless required by the manufacturer, hospital policy, or other evidence-based guidelines. It is not appropriate to use prefilled saline flush syringes to dilute or reconstitute IV medications unless approved for this use by the U.S. Food and Drug Administration (FDA; see the label of the product you use).

Secondary Infusion Bags:

Certain medications may be available in more than one form (e.g., Mini-Bag Plus, ADD-Vantage™, Duplex®); follow the manufacturer's directions for reconstitution and stability. Appropriate diluents are listed, but refer to local protocols and standards. Standardization of concentrations is advised and guided by organizations such as the American Society of Health-System Pharmacists' Standardize 4 Safety initiative. Links to selected standards are listed here: National Adult Continuous Infusion Standards are available at https://www.ashp.org/-/media/assets/pharmacy-practice/s4s/docs/Adult-Infusion-Standards.pdf and pediatric standards are available at https://www.ashp.org/-/media/assets/pharmacy-practice/s4s/docs/Pediatric-Infusion-Standards.pdf.

The Solution Compatibility Chart on the inside back cover has been expanded and updated. For pediatric patients, most come diluted from the pharmacy, and standard concentrations for pediatric medications should be established locally. For any medication that must be diluted by the nurse prior to administering, please refer to the front pages entitled Preparation and Administration of Injectable Medications. Generic dilution charts for grams to milligrams and milligrams to micrograms are featured on the inside front cover and facing page.

Filters:

A medication in a glass ampule should be filtered when drawn up to eliminate the possibility of glass shards being injected. A filter needle or filter straw is used to draw the solution from the ampule, and that device is replaced with a standard needle to inject into a bag or contents administered to a patient through a needleless port. Use of an in-line filter device for medications should be done according to local protocol or manufacturer guidance. Multiple in-line filters are available, and pore size should be matched to the product being administered. Consult your pharmacist if more information is needed than is provided in this book.

Storage:

Medications prepared at the site of administration should be administered within 4 hours unless specifically noted on the label or in medication information sources and should be used only for a single patient. The product should be labeled completely (patient name, medication, concentration, date and time prepared, and initials of person doing the preparation) unless administered immediately. Aseptic intravenous compounding will generally be done in special clean rooms and the final product delivered to the location of the patient. Sterile compounded solutions should be properly labeled for an individual patient and stored under optimal conditions—generally refrigerated, although some medications should stay at room temperature. This detail should be on the product along with a label suggesting either "do not use" beyond a specific date (beyond use date, or BUD) and time or "do not hang" after a specific date and time (although these can generally hang for up to 24 additional hours). Consult local policies for specific terminology and standards.

COMPATIBILITIES

The focus of this section is **compatibility** between two medications. **Any medication not listed as compatible should be considered incompatible**. Only the manufacturer's recommendations for **compatibility** or **incompatibility** are listed and may be specific to the concentration and/or solution. No third-party compatibilities or incompatibilities are listed. Multiple medications are sometimes administered through the same site, but that compatibility is often not studied or defined.

A manufacturer's listing may include detailed information on potential interaction with specific plastic tubing/containers or other medications or devices. If the manufacturer provides no information, that will be stated.

If there are other sources that list specific compatibilities dependent on concentration or manufacturer, a statement to this effect follows so you know other compatibilities may exist. An updated digital database (e.g., Lexicomp, Trissels, Micromedex, King Guide, Clinical Pharmacology) may be available in your location. Wall charts are not ideal for this purpose due to their rapidly becoming outdated. Always consult a pharmacist for clarification of compatibilities, specific concentrations, or doses.

Administration of IV Infusion:

What steps should you consider before administering any medication? Please refer to the new section at the front of the book entitled Preparation and Administration of Injectable Medications. If the medication you wish to administer is not listed in the **Compatibility** section, ***consider it to be incompatible***. If you are unable to discontinue the infusion of an incompatible drug, you must have another IV access.

RATE OF ADMINISTRATION:

Accepted rates of administration are listed. Potential adverse effects from too rapid or slow injection rates are also listed but may not be complete. Suggested rates for infants, children, or the elderly are listed when available and are often administered with the aid of a controlled infusion device. Although the speed that a medication is given via IV push may be important, for small-volume doses it is the rate of flush following the medication that dictates delivery into the vasculature. The residual volume from the administration site (Y-site or needleless connector) and the vascular device fill volume must be factored into the rate of administration. Do not use running IV fluid to control the rate of administration. Charts are available in selected monographs.

MEDICATION ACTIONS:

Clear, concise statements outline the origin of each medication, how it affects body systems, its length of action, and methods of excretion. If a medication crosses the placental barrier or is secreted in breast milk, it will be mentioned here if that information is available.

INDICATIONS AND USES:

When a medication is reviewed by the FDA, it is labeled for specific indications. Once a medication is marketed, prescribers are allowed to use it for other indications, ideally with adequate supporting literature (known as "off-label" use) or under a specific protocol for the facility. However, specific contraindications, warnings, and precautions should be evaluated prior to use, including consideration of pregnancy, breastfeeding, extremes of age or weight, medication interactions, and potential adverse effects, and care setting. **Limitations of Use** are now being identified by the manufacturer in FDA-approved labeling to describe situations where the risk-to-benefit profile of a medication is uncertain and has implications for the safe and effective use of the medication.

CONTRAINDICATIONS:

Contraindications are situations where the medication should not be used, and this book includes those specifically listed by the manufacturer in the approved label. Consult with the prescriber if an ordered medication is contraindicated for the patient.

PRECAUTIONS:

The section on precautions covers many areas of information needed before injecting any medication, including Black Box Warnings from the prescribing information as previously defined. **Black Box Warning statements are shaded** in light gray, **and a different typeface is used** for instant identification wherever they appear in the text. The range of information in this category covers all facets not covered under specific headings. Additional subdivisions may be included.

Monitor:

This subheading includes information such as required prerequisites for medication administration, parameters for evaluation, and patient assessments.

Patient Education:

This subheading addresses only specific, important issues required for short-term IV use. It is expected that the health professional will review the major points in the medication profile with the patient, including name of medication, purpose, effects and side effects, special instructions, and duration of treatment. There are certain medications that require a Risk Evaluation and Mitigation Strategy (REMS), which is a medication safety program that the FDA can require for certain medications with serious safety concerns to help ensure that the benefits of the medication outweigh its risk. Medications with a REMS are noted in the patient education section.

Maternal/Child:

This subheading addresses use in pregnancy, childbirth, and lactation; safety for use in pediatric patients; and any special impact on infants and neonates.

Elderly:

This subheading is included whenever specific information impacting this patient group is available. The Beers Criteria for Potentially Inappropriate Medication Use in Older Adults recommendations are incorporated into the guidance regarding medications that should be avoided in most older patients or in certain situations. For more information on Beers criteria, see https://dcri.org/beers-criteria-medication-list. Always consider age-related organ impairment (e.g., cardiac, hepatic, renal, insufficient bone marrow reserve), history of previous or concomitant disease or medication therapy, and route of excretion when determining dose and evaluating side effects.

DRUG/LAB INTERACTIONS:

Drug/drug or drug/lab interactions are listed here. To help identify these interactions more easily, **single medications, medication categories when there are multiple medications, and specific tests are in boldface type**. If a potential interaction within the patient's medication profile is noted, consult a pharmacist immediately. Interactions may increase or decrease medication effectiveness or alter the likelihood of an adverse effect. Check with the lab first on drug/lab interactions; acceptable monitoring alternatives may be available. After this consultation, notify the prescriber if appropriate. To facilitate recognition, common trade names accompany generic names or examples are presented.

SIDE EFFECTS:

In some monographs, the most common side effects may be listed first, followed by the most serious side effects. In all monographs, they are listed in alphabetical order. Specific symptoms of overdose are listed where available or distinct from usual doses.

ANTIDOTE:

Specific antidotes are listed in this section if available. In addition, specific nursing actions to reverse undesirable side effects are listed.

Within a heading, there may be references to other sections within an individual monograph (e.g., see Precautions, see Monitor, see Dose Adjustments, see Maternal/Child). These references indicate additional requirements and should be consulted before administering the medication.

Key to Abbreviations

<	less than
>	more than
¼NS	one-fourth normal saline (0.2%)
⅓NS	one-third normal saline (0.33%)
½NS	one-half normal saline (0.45%)
ABGs	arterial blood gases
ACE	angiotensin-converting enzyme
ACT	activated coagulation time
ACTH	adrenocorticotropic hormone
AF	atrial fibrillation
A/G	albumin-to-globulin ratio
AIDS	acquired immunodeficiency syndrome
ALT	alanine aminotransferase (SGPT)
AMI	acute myocardial infarction
ANC	absolute neutrophil count
aPTT	activated partial thromboplastin time
ARDS	adult respiratory distress syndrome/acute respiratory distress syndrome
AST	aspartate aminotransferase (SGOT)
AUC	area under the curve
AV	atrioventricular
BMD	bone mass density
BP	blood pressure
BSA	body surface area
BUN	blood urea nitrogen

BWFI	bacteriostatic water for injection
C	Celsius
Ca	calcium
CABG	coronary artery bypass graft
CAD	coronary artery disease
CAPD	continuous ambulatory peritoneal dialysis
CBC	complete blood cell count
CDAD	*Clostridium difficile*–associated diarrhea
CHF	congestive heart failure
Cl	chloride
CMV	cytomegalovirus
CNS	central nervous system
CO_2	carbon dioxide
COPD	chronic obstructive pulmonary disease
CPK	creatine kinase
CrCl	creatinine clearance
CRF	chronic renal failure
CRT	controlled room temperature (20°C to 25°C; 68°F to 77°F)
CSF	cerebrospinal fluid
C/S	culture and sensitivity
CTCAE	Common Terminology Criteria for Adverse Events
CVA	cerebrovascular accident
CVP	central venous pressure
D10NS	10% dextrose in normal saline
D10W	10% dextrose in water
D5/¼NS	5% dextrose in one-quarter normal saline (0.2%)
D5/⅓NS	5% dextrose in one-third normal saline (0.33%)
D5/½NS	5% dextrose in one-half normal saline (0.45%)
D5LR	5% dextrose in lactated Ringer’s solution
D5NS	5% dextrose in normal saline
D5R	5% dextrose in Ringer’s solution

D5W	5% dextrose in water
DC	discontinued
DEHP	diethylhexylphthalate
DIC	disseminated intravascular coagulation
dL	deciliter(s) (100 mL)
dMMR	deficient mismatch repair
DNA	deoxyribonucleic acid
ECG	electrocardiogram
EEG	electroencephalogram
eGFR	estimated glomerular filtration rate
ESRD	end-stage renal disease
F	Fahrenheit
FSH	follicle-stimulating hormone
GI	gastrointestinal
GFR	glomerular filtration rate
GGT	gamma-glutamyl transferase
Gm	gram(s)
gr	grain(s)
gtt	drop(s)
GU	genitourinary
Hb	hemoglobin
Hct	hematocrit
HCV	hepatitis C virus
Hg	mercury
HIV	human immunodeficiency virus
hr	hour
HR	heart rate
HSCT	hematopoietic stem cell transplant
IBW	ideal body weight
ICU	intensive care unit

IgA	immune globulin A
IGIV	immune globulin intravenous
ÍL	microliters, µL, mm^3
IM	intramuscular
INR	international normalized ratio
IP	intrapleural
IU	international unit(s)
IV	intravenous
IVIG	intravenous immunoglobulin
K	potassium
KCl	potassium chloride
kg	kilogram(s)
L	liter(s)
lb	pound(s)
LDH	lactic dehydrogenase
LFT	liver function test
LH	luteinizing hormone
LR	lactated Ringer’s injection or solution
M	molar
m^2	meter squared
MAO	monoamine oxidase
MAP	mean arterial pressure
mcg	microgram(s)
mCi	millicurie(s)
mEq	milliequivalent
Mg	magnesium
mg	milligram(s)
MI	myocardial infarction
min	minute
mL	milliliter

mmol	millimole(s)
mm^3	cubic millimeters, μL, ÍL
MDRSP	multidrug-resistant *Streptococcus pneumoniae*
MRI	magnetic resonance imaging
MSI-H	microsatellite instability-high
Na	sodium
NaCl	sodium chloride
NCI	National Cancer Institute; see CTCAE
ng	nanogram (millimicrogram)
NS	normal saline (0.9%)
NSAID	nonsteroidal anti-inflammatory drug
NSCLC	non–small-cell lung cancer
NSR	normal sinus rhythm
N/V	nausea and vomiting
OTC	over-the-counter
PAC	premature atrial contraction
PaO_2	arterial oxygen pressure
PCA	patient-controlled analgesia
PCP	*Pneumocystis jiroveci* pneumonia
pg	picogram
pH	hydrogen ion concentration
PML	progressive multifocal leukoencephalopathy
PO	by mouth/orally
PRCA	pure red cell aplasia
PRES	posterior reversible encephalopathy syndrome
PSVT	paroxysmal supraventricular tachycardia
PT	prothrombin time
PTT	partial thromboplastin time
PVC	polyvinyl chloride; premature ventricular contraction
R	Ringer's injection or solution
RBC	red blood cell

refrigerate	temperature at 2°C to 8°C (36°F to 46°F)
RNA	ribonucleic acid
RPLS	reversible posterior leukoencephalopathy syndrome
RT	room temperature
RTS	room-temperature stable
SA	sinoatrial
SC	subcutaneous
SIADH	syndrome of inappropriate antidiuretic hormone
SOB	shortness of breath
SCr	serum creatinine
S/S	signs and symptoms
SW or SWI	sterile water for injection
TEN	toxic epidermal necrolysis
TIA	transient ischemic attacks
TLS	tumor lysis syndrome
TNA	3-in-1 combination of amino acids, glucose, and fat emulsion
TPN	2-in-1 combination of amino acids and glucose; total parenteral nutrition
TRALI	transfusion-related acute lung injury
TSH	thyroid-stimulating hormone
TT	thrombin time
μL	microliters, mm^3 , ÍL
ULN	upper limits of normal
URI	upper respiratory infection
UTI	urinary tract infection
VEGF	vascular endothelial growth factor
VF	ventricular fibrillation
VS	vital signs
VT	ventricular tachycardia
v/v	volume-to-volume ratio

WBC	white blood cell
WBCT	whole blood clotting time
w/v	weight-to-volume ratio
w/w	weight-to-weight ratio

Important IV Therapy Facts

- Read the Preface and the Format and Content of *Intravenous Medications* sections at least once. They'll answer many of your questions and save you time.

USUAL DOSE

- Doses calculated on body weight are usually based on pretreatment weight and not on edematous weight.
- Normal renal or hepatic function is usually required for drugs metabolized by these routes.
- Formula to calculate creatinine clearance (CrCl) from serum creatinine value (Cockcroft–Gault equation):
  Males: $\frac{\text{Weight in kg} \times (140 - \text{Age in years})}{72 \times \text{Serum creatinine (mg/dL)}} = \text{CrCl}$
  Females: 0.85 × Male CrCl value calculated from above formula.
- Children: $K \times \frac{\text{Linear length or height (cm)}}{\text{SCr (mg/100 mL)}}$
  K for children >1 year of age = 0.55
  K for infants = 0.45
- Lean Body Weight (LBW)
  Males: 50 kg + 2.3 kg for each inch over 5 feet
  Females: 45.5 kg + 2.3 kg for each inch over 5 feet
  Children weighing 15 kg or less: Use actual body weight in kg
- Formula to calculate body surface area (BSA):

$$\text{BSA } (\text{M}^2) = \sqrt{\frac{\text{Height (cm)} \times \text{Weight (kg)}}{3600}}$$

- To prevent unintentional overdose, a premixed solution such as DUPLEX or Galaxy containers available in a specific dose (e.g., 1 Gm, 2 Gm) should be used in pediatric patients *only when the individual dose is the entire contents of the container and not any fraction thereof.*

DILUTION

- Check all labels (drugs, diluents, and solutions) to confirm appropriateness for IV use.
- Sterile technique is imperative in all phases of preparation.
- Use a filter needle when withdrawing IV meds from ampules to eliminate

possible pieces of glass.

- Pearls:
  1 Gm in 1 Liter yields 1 mg/mL.
  1 mg in 1 Liter yields 1 mcg/mL.
  % of a solution equals the number of grams/100 mL (5% = 5 Gm/100 mL).
- Pediatric dilution:
  If you dilute 6.0 mg/kg in 100 mL, 1 mL/hr equals 1.0 mcg/kg/min.
  If you dilute 0.6 mg/kg in 100 mL, 1 mL/hr equals 0.1 mcg/kg/min.
- To prevent unintentional overdose, a premixed solution such as DUPLEX or Galaxy containers available in a specific dose (e.g., 1 Gm, 2 Gm) should be used in pediatric patients *only when the individual dose is the entire contents of the container and not any fraction thereof.*
- See charts on inside front cover.
- Do not use bacteriostatic diluents containing benzyl alcohol for neonates, as doing so may cause a fatal toxic syndrome. Signs and symptoms (S/S) include CNS depression, hypotension, intracranial hemorrhage, metabolic acidosis, renal failure, respiratory problems, and seizures.
- Ensure adequate mixing of all drugs added to a solution.
- When combining drugs in a solution (additives), always consider the required rate adjustment of each drug.
- Examine solutions for clarity and any possible leakage.
- Frozen infusion solutions should be thawed at room temperature (25°C; 77°F) or under refrigeration. Do not force by immersion in water baths or in the microwave. All ice crystals must be melted before administration. Do not refreeze.
- Syringe prepackaging for use in specific pumps is now available for many drugs. Concentrations are often the strongest permissible, but length of delivery is accurate.
- Controlled room temperature (CRT) is considered to be 25°C (77°F). Most medications tolerate variations in temperature from 15°C to 30°C (59°F to 86°F).

INCOMPATIBILITIES

- Some manufacturers routinely suggest discontinuing the primary IV for intermittent infusion, which is usually done to avoid any possibility of incompatibility. Flushing the line before and after administration may be indicated and/or appropriate for some drugs.
- The brand of intravenous fluids or additives, concentrations, containers, rate and order of mixing, pH, and temperature all affect solubility and compatibility. Consult your pharmacist with any questions, and document appropriate instructions on the care plan.

TECHNIQUES

- **Do not hang** IV infusions in flexible plastic containers **in series connection,**

do not pressurize IV infusions in flexible plastic containers **to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets** with IV infusions in flexible plastic containers. **All may result in air embolism.**

- Confirm the patency of peripheral and/or central sites. Avoid extravasation.
- Avoid accidental arterial injection, as it can cause gangrene.

RATE OF ADMINISTRATION

- Life-threatening reactions (time-related overdose or allergy) are frequently precipitated by a too-rapid rate of injection.
- If a common IV line is used to administer other drugs through the same IV line, flush the IV line before and after each infusion with a compatible solution (e.g., NS, D5W). When flushing before administration, be sure to flush with an amount adequate to clear the previous drug (e.g., mL of drug or mL of lumen of catheter). When flushing after administration, be sure to flush with an amount at least equal to that of the drug administered (e.g., mL of drug or mL of lumen of catheter).

PATIENT EDUCATION

- A well-informed patient is a great asset; review all appropriate drug information with every conscious patient.

SIDE EFFECTS

- Reactions may be caused by a side effect of the drug itself, allergic response, overdose, or the underlying disease process.

Resources

PUBLICATIONS

The following publications have been used as a resource to assemble the information found in *Intravenous Medications*. Additional and more detailed information on drugs may be found in these publications:

American Hospital Formulary Service Drug Information, 2020, Bethesda, MD, American Society of Health-System Pharmacists (updated via website).

Preparation and Administration of Injectable Drugs

Follow these steps after order verification and the appropriate steps for safe medication use.

GENERAL CONSIDERATIONS

Medications are prepared at the bedside when they are not provided in ready-to-administer form by the pharmacy or if the product stability requires preparation immediately before administration. Here is a simple list of **Do's and Don'ts**.

DO	DON'T
• Gather materials (drug, diluent, disinfecting swabs/devices, syringes, needles, label) onto a clean surface (general aseptic field) in a location without interruptions, away from sinks or other sources of contamination.	• Prepare hazardous drugs outside of approved areas (follow safe handling procedures).
• Perform hand hygiene.	• Re-use a single-use vial.
• Inspect materials for integrity (packaging clean, dry, and intact/undamaged) and expiration date.	• Use a multi-use vial on more than one patient unless local policies describe specific exceptions.
• Disinfect surfaces such as the vial, ampule neck, and injection site on a bag and let the product dry.	• Withdraw drug from a commercially available ready-to-use cartridge syringe.
• Keep key parts and key sites sterile.	• Dilute unless directed by the manufacturer.
• Add a tip cap to a syringe if not immediately administered.	• Use a saline flush solution from a prefilled syringe to dilute or reconstitute a drug unless the flush syringe is labeled for that use.
• Label the product with the patient name, drug name, strength/dose, and time if not	• Recap used needles.

immediately administered.	
• Dispose of extra drug, used needles, and syringes in an approved device/location.	• Reuse a sterile saline flush syringe, even on the same patient.
• Obtain an independent double-check for high-alert medications according to local policies.	• Use the product more than 4 hours after preparation.
• Disinfect the injection port on IV tubing according to the device directions prior to administration.	

PROCEDURES

Preparing a Medication from an Ampule

1. Disinfect the neck of the ampule prior to entry and allow the disinfectant to dry.
2. Flick the ampule to ensure that all drug is in the body of the container.
3. Using a paper towel or gauze square, snap the neck of the ampule away from your body.
4. Use a syringe that is the appropriate size for the volume to be given to draw up the dose.
5. Take the cap off of the filter needle/straw, place your sterile needle/straw into the ampule, and draw up the needed amount of liquid.
6. Dispose of the ampule glass in a sharps container.
7. Remove the filter needle (do not inject through a filter needle); use a new sterile needle if injecting into a bag.
8. Refer to general considerations above.

Preparing a Medication from a Vial

1. Disinfect vial septum (the plastic cap on a vial is not a sterile barrier) and allow the disinfectant to dry.
2. Use a blunt needle to remove the contents of the vial.
3. To draw up the dose, use a syringe that is the appropriate size for the volume to be given.
4. Insert the needle into the vial, invert the vial, and withdraw the vial contents into the syringe.
5. Adjust the volume in the syringe according to the prescribed dose; some vials contain overfill, or the prescribed dose is less than the vial contents.
6. Dispose of the used syringe/needle safely after use.
7. Refer to general considerations above.

Reconstituting a Drug

Reconstitution is the process of adding a liquid diluent to a dry drug to make a specific concentration of liquid drug.

1. Disinfect the septum of the diluent and drug vials (the plastic cap on a vial is not a sterile barrier).
2. Attach a blunt needle to a syringe.
3. Pull the plunger back on the syringe to the volume of diluent you plan to withdraw (this will prevent a vacuum from forming) and inject air into the diluent vial.
4. Keeping the same needle and syringe in the vial, withdraw the amount of diluent needed.
5. Remove the syringe/needle from the diluent vial.
6. Inject the diluent into the powdered medication vial. Direct the solution toward the wall of the vial to minimize foaming.
7. Remove the syringe and needle from the vial.
    a. Swirl the vial to dissolve the drug.
    b. Inspect to ensure that the drug is dissolved and that no visible particles remain.
8. Withdraw the ordered dose of drug into a new sterile syringe of an appropriate size for the dose, using a new needle, and dispose of the used needle safely in a sharps container.
9. Refer to general considerations above.

Diluting a Drug

Dilution is the process of adding a liquid diluent to a liquid drug to make a specific concentration of the liquid drug.

1. Only dilute a liquid drug when recommended by manufacturer or local policy.
2. Using the steps above, draw the drug into the appropriately sized syringe.
3. Using the same needle and syringe, insert the needle into the diluent vial and withdraw the appropriate amount of diluent. **Do not inject the drug into the diluent vial**.
4. Remove the needle and syringe from the vial. Swirl gently to mix.
5. Remove the needle prior to attaching to needleless injection port or replace with tip cap.
    a. Do not use a saline flush solution from a prefilled syringe to dilute a medication.
    b. Do not inject a medication into another syringe through the syringe tip.

Preparing an Infusion Bag

1. Obtain or draw up the exact amount of drug to be added to the bag using the procedures described above.
    a. No more than two drugs may be added to an infusion bag when prepared outside the pharmacy.
2. Remove bag overwrap.
3. Disinfect the injection port on the bag and inject the drug.
4. Mix gently to ensure the drug is completely distributed.
5. Label and use within 4 hours as directed above.

IV Push Administration

1. Use barcode scanning if not already done or repeat the “rights” for safe medication use.
    a. Obtain an independent double check as appropriate for local policies.
2. Confirm vascular access patency with a flush/aspiration prior to each use and ensure appropriateness of that site for the drug and concentration to be administered.
    a. Use a 10-mL-diameter syringe to assess patency and give initial flush for central lines.
    b. Always use two sterile saline flush syringes, one before and one after medication administration. Do not reuse saline flush syringes.
3. Disinfect the needleless injection port of tubing, nearest the patient.
4. Stop the infusion.
5. Flush tubing with the first sterile saline flush syringe to clear IV fluids and injection port.
6. Attach medication syringe to the injection port and inject at the prescribed rate of administration.
7. Remove drug syringe.
8. Disinfect injection port.
9. Flush tubing with a second sterile saline flush syringe. Inject flush at the same rate as the medication rate of administration. (This is how the drug is administered completely at the desired rate).
    a. Never leave a syringe attached to an injection port.
10. Lock the vascular access device according to the device and local practice protocols or resume primary infusion.
11. Document drug administration if not already completed.

IVPB Administration

1. Use barcode scanning if not already done or repeat the “rights” for safe medication use.
    a. Obtain an independent double check as appropriate for local policies.
2. Confirm vascular access patency with a flush/aspiration prior to each use, and ensure appropriateness of that site for the drug and concentration to be administered.
    a. Use a 10-mL-diameter syringe to assess patency and give initial flush for central lines.
3. Disinfect the needleless injection port of tubing (per device directions) containing a compatible solution.
    a. Choose a port above the infusion device where it will control the IVPB rate.
    b. Do not interrupt a continuous therapeutic infusion for an IVPB drug.
4. If the drug and primary fluid are **not compatible**, stop the infusion and flush tubing with saline or dextrose as appropriate for the drug per the drug manufacturer’s directions prior to drug administration.
    a. After the drug injection or infusion, repeat flush with saline/dextrose as compatible.

5. If the drug and primary fluid are **compatible**, you may continue the primary infusion or use the infusion pump/device to control which fluid infuses per local protocols.
6. Disinfect the port prior to each insertion including saline flush.
7. Lock the vascular access device according to the device and local practice protocols or resume primary infusion.
8. Document drug administration if not already completed.

Note that some drugs will be supplied with specific materials to facilitate preparation. Follow the manufacturer's guidelines for the use of those products.
Consult the Infusion Nurses Society Infusion Therapy Standards of Practice for detailed information, and always know the local practice policies and procedures.

ABATACEPT

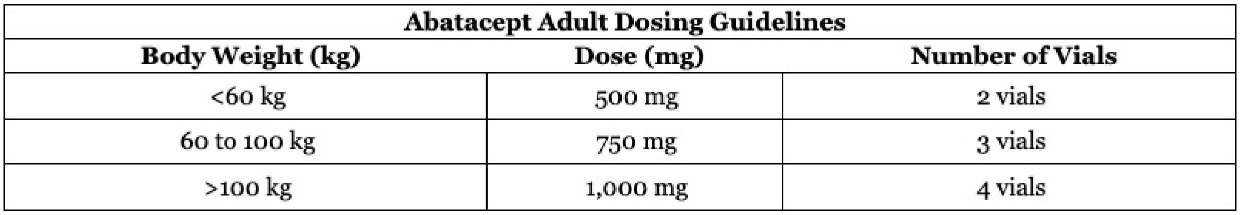
(a-**BAY**-ta-sept)
Orencia
Antirheumatic
Disease-modifying agent
Selective T-cell costimulation blocker
pH 7.2 to 7.8

USUAL DOSE

Pretreatment:

Pretesting required; see Monitor. See Maternal/Child.

Dose is based on body weight in kilograms as shown in the following chart. After the initial dose, repeat administration at 2 and 4 weeks. Administer every 4 weeks thereafter. May be used as monotherapy or concomitantly with disease-modifying antirheumatic drugs (DMARDs) other than TNF antagonists; see Contraindications and Drug Interactions. May be given by SC injection or as an IV infusion; formulation and dose are different; see Indications and prescribing information.



Abatacept Adult Dosing Guidelines		
Body Weight (kg)	**Dose (mg)**	**Number of Vials**
<60 kg	500 mg	2 vials
60 to 100 kg	750 mg	3 vials
>100 kg	1,000 mg	4 vials

Patients transitioning from IV therapy to subcutaneous administration should administer the first subcutaneous dose instead of the next scheduled IV dose. Abatacept is dosed weekly in the subcutaneous regimen. When administered for treatment of rheumatoid arthritis, it may be initiated with or without an IV loading dose. If the subcutaneous regimen is initiated with an IV loading dose, determine loading dose as outlined in the previous chart. The first subcutaneous injection should be administered within a day of the IV loading dose. A loading dose **is not** used when administered for treatment of psoriatic arthritis.

PEDIATRIC DOSE

May be given by SC injection (2 years of age and older) or as an IV infusion (6 years of age and older) in pediatric patients. Formulation and dose are different; see Indications and prescribing information. When administered subcutaneously, **do not** administer an IV loading dose. May be used as monotherapy or concomitantly with methotrexate.

Pediatric patients 6 to 17 years of age who weigh less than 75 kg:

10 mg/kg/dose based on patient's body weight at each administration. After the initial dose, repeat administration at 2 and 4 weeks. Administer every 4 weeks thereafter.

Pediatric patients 6 to 17 years of age who weigh more than 75 kg:

See Usual Dose and the Abatacept Adult Dosing Guidelines chart. Do not exceed a maximum dose of 1,000 mg.

DOSE ADJUSTMENTS

There is a trend toward a higher clearance with increasing body weight; see Usual Dose. No specific dose adjustments are required based on age or gender when corrected for body weight. ■ The effects of renal or hepatic impairment have not been studied.

DILUTION

Using ***ONLY the silicone-free disposable syringe provided*** with each vial and an 18- to 21-gauge needle, reconstitute each 250-mg vial with 10 mL SWFI; final concentration is 25 mg/mL. (If reconstituted with a siliconized syringe, the solution must be discarded.) Direct stream of SWFI toward side of vial. Do not use vial if vacuum is not present. Rotate or swirl vial gently until contents have dissolved. Do not shake. After dissolution, vent vial with a needle to dissipate any foam that may be present. Solution should be clear and colorless to pale yellow. Reconstituted solution must be further diluted to 100 mL as follows: From a 100-mL infusion bag or bottle, withdraw a volume of NS equal to the volume of reconstituted abatacept solution required for the patient's dose (for 2 vials, remove 20 mL; for 3 vials, remove 30 mL; for 4 vials, remove 40 mL). Using the ***same silicone-free disposable syringe provided,*** slowly add the reconstituted abatacept into the infusion bag or bottle. Mix gently.

Orencia prefilled syringes and Orencia ClickJet autoinjectors are intended for subcutaneous use only and are not intended for IV infusion.

Filter:

Administration through a 0.2- to 1.2-micron, nonpyrogenic, low–protein binding filter is required.

Storage:

Refrigerate unopened vials at 2° to 8°C (36° to 46°F). Do not use beyond expiration date. Protect from light by storing in original packaging. Before administration, the diluted solution may be stored at RT or refrigerated; however, infusion of the diluted solution should be completed within 24 hours of reconstitution. Discard diluted solution if not administered within 24 hours. Any unused portion in a vial must be discarded.

COMPATIBILITY

Manufacturer states, “Should not be infused concomitantly in the same intravenous line with other agents.” **Compatibility** studies have not been performed.

RATE OF ADMINISTRATION

Administration through a 0.2- to 1.2-micron, nonpyrogenic, low–protein binding filter is required.

A single dose equally distributed over 30 minutes.

ACTIONS

A selective T-cell costimulation modulator. Acts as a selective biologic response modulator by inhibiting T-lymphocyte activation. Activated T-lymphocytes are implicated in the pathogenesis of rheumatoid arthritis and psoriatic arthritis. Abatacept reduces pain and joint inflammation and slows the progression of structural damage to bone and cartilage. Mean half-life is 13.1 days (range 8 to 25 days).

INDICATIONS AND USES

Reduce the S/S, induce a major clinical response, inhibit the progression of structural damage, and improve the physical function in adult patients with moderately to severely active rheumatoid arthritis. May be used as monotherapy or concomitantly with DMARDs other than TNF antagonists. May be given IV or SC. Adult infusion patients may transition to SC injection; see prescribing information. ■ Reduce the S/S in pediatric patients 2 years of age and older with moderately to severely active polyarticular juvenile idiopathic arthritis. May be used as monotherapy or concomitantly with methotrexate. SC injection may be used in pediatric patients 2 years of age and older. IV dosing has not been studied in patients younger than 6 years of age; see prescribing information. ■ Treatment of adult patients with active psoriatic arthritis. May be used with or without nonbiologic DMARDs.

Limitation of use:

Should not be administered concomitantly with TNF antagonists (e.g., adalimumab [Humira], etanercept [Enbrel]) or other biologic rheumatoid arthritis therapy, such as anakinra (Kineret).

CONTRAINDICATIONS

Manufacturer states, “None.” Consider known hypersensitivity to abatacept or any of its components (maltose, monobasic sodium phosphate). See Limitation of Use and Drug/Lab Interactions.

PRECAUTIONS

Concurrent use with a TNF antagonist (e.g., adalimumab [Humira], etanercept [Enbrel]) is associated with an increased risk of infections with no associated increased efficacy when compared with use of the TNF antagonist alone. Concurrent use is not recommended; see Limitation of Use, Contraindications, and Drug/Lab Interactions. ■

Hypersensitivity reactions, including anaphylaxis, have been reported and can occur after the first infusion. Emergency medical equipment and medications for treating these reactions must be readily available. ■ Serious infections, including sepsis and pneumonia, have been reported; some have been fatal. Patients receiving concomitant immunosuppressive therapy may be at increased risk. ■ Use caution in patients with a history of recurrent infections, underlying conditions that may predispose them to infections, or chronic, latent, or localized infections; see Monitor. ■ Antirheumatic therapies have been associated with hepatitis B reactivation. ■ Use with caution in patients with COPD. May be at increased risk for developing respiratory adverse events (e.g., COPD exacerbation, cough, dyspnea, rhonchi). ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ T-cells mediate cellular immune responses. Drugs that inhibit T-cell activation, including abatacept, may affect patient defenses against infection and malignancies. The impact of abatacept on the development and course of malignancies is not fully understood. ■ See Maternal/Child.

Monitor:

Evaluate patients for latent tuberculosis (TB) with a TB skin test. Patients testing positive in TB screening should be treated with a standard TB regimen before initiating therapy with abatacept. ■ Screening for viral hepatitis should be performed before initiating therapy with abatacept. ■ Monitor for S/S of infection, especially if transitioning patient from TNF antagonist therapy to therapy with abatacept. Discontinue therapy if a serious infection develops. ■ Monitor COPD patients for worsening of respiratory status. ■ Monitor for S/S of hypersensitivity or infusion-related reactions; see Side Effects. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Read manufacturer’s patient information sheet before each infusion. ■ Review disease states, medication list, and vaccination status with physician; see Precautions. ■ Report S/S of allergic reaction (e.g., rash, itching, wheezing), infusion reaction (e.g., dizziness, headache), or infection promptly. Discuss previous infections, current infections, or exposure to TB. Educate patient of increased risk of infections and to consider wearing mask in indoor crowded situations.

Maternal/Child:

Safety for use in pregnancy has not been established. Use caution. ■ There is no information regarding the presence of abatacept in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ A pregnancy registry has been established; contact manufacturer. ■ Safety and effectiveness for use in pediatric patients under 2 years of age not established. IV dosing has not been studied in patients younger than 6 years of age. ■ Safety and effectiveness for uses other than juvenile idiopathic arthritis in pediatric patients have not been established. ■ Patients with juvenile idiopathic arthritis should be brought up-to-date with all immunizations before initiating therapy with abatacept. ■ Because it is unknown whether abatacept can cross the placenta and because it is an immunomodulatory agent, the safety of administering live vaccines to infants exposed to abatacept in utero is unknown. Consider risk versus benefit.

Elderly:

Specific differences in safety and efficacy not noted. The frequency of serious infection and malignancy in patients over 65 years of age was greater than for those under age 65. However, there is a higher incidence of infection and malignancy in the elderly population in general. Use caution; see Precautions.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Methotrexate, NSAIDs, corticosteroids, and TNF antagonists do not appear to influence abatacept clearance. ■ Concurrent use with a **TNF antagonist** (e.g., adalimumab, etanercept, infliximab) is associated with an increased risk of serious infections and no significant additional efficacy over use of the TNF antagonist alone. Concurrent use is not recommended. ■ With the IV formulation, falsely elevated blood glucose readings may occur on the day of the infusion with **specific blood glucose monitoring systems** that react to drug products containing maltose. IV formulation contains maltose; SC formulation does not contain maltose; see prescribing information. ■ Safety and efficacy of concurrent use with **anakinra** has not been established. Concurrent use is not recommended. ■ **Live virus vaccines** should not be given concurrently with or within 3 months of abatacept. ■ May blunt the effectiveness of some **vaccinations.**

SIDE EFFECTS

In adult and pediatric patients, side effects are similar in type and frequency. The most commonly reported side effects are headache, nasopharyngitis, nausea, and upper respiratory tract infections. The most serious adverse effects are infections and malignancies. Infections are the most likely adverse event to cause interruption or discontinuation of therapy. Acute infusion-related reactions (cough, dizziness, dyspnea, flushing, headache, hypertension, hypotension, nausea, pruritus, rash, urticaria, wheezing) have been reported and usually occur within 1 hour of the infusion. Hypersensitivity reactions (anaphylaxis [rare], dyspnea, hypotension, urticaria) have been reported, usually within 24 hours of infusion. Other reactions include back or extremity pain, COPD exacerbation, dyspepsia, immunogenicity (antibody formation), and rhonchi.

Post-Marketing:

New or worsening psoriasis and vasculitis (including cutaneous vasculitis and leukocytoclastic vasculitis).

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. During clinical studies, most infusion-related reactions were mild to moderate, and therapy was discontinued in very few patients. Discontinue abatacept for any serious reaction or infection. Therapy may need to be interrupted in patients who develop infections. Treat infusion and hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary.

ACETAMINOPHEN BBW

(ah-**SEAT**-ah-**MIN**-oh-fen)
Ofirmev
Antipyretic
Analgesic
pH 5.5

USUAL DOSE

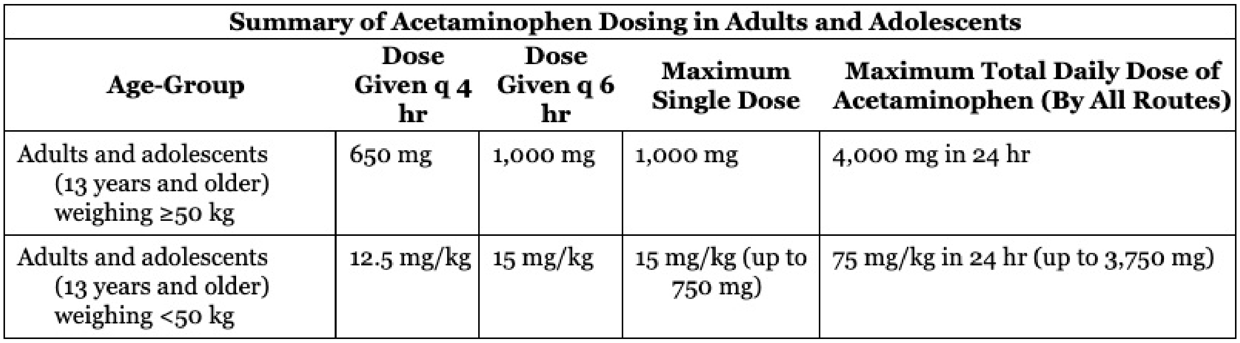
Pretreatment:

Baseline studies may be indicated; see Monitor.

May be given as a single or repeated dose. Minimum dosing interval is 4 hours. No dose adjustment is necessary when converting from oral to IV dosing.

Care must be taken to avoid dosing errors, which could result in accidental overdose and death. In particular, be careful to ensure that:

- Dose in milligrams and milliliters is not confused
- Dosing is based on weight (using kg, not pounds) for patients under 50 kg
- Infusion pump is programmed properly
- Total daily dose of acetaminophen from all sources (i.e., all routes [IV, oral, and rectal]) and all acetaminophen-containing products does not exceed maximum daily limits.



Summary of Acetaminophen Dosing in Adults and Adolescents

Age-Group	Dose Given q 4 hr	Dose Given q 6 hr	Maximum Single Dose	Maximum Total Daily Dose of Acetaminophen (By All Routes)
Adults and adolescents (13 years and older) weighing ≥50 kg	650 mg	1,000 mg	1,000 mg	4,000 mg in 24 hr
Adults and adolescents (13 years and older) weighing <50 kg	12.5 mg/kg	15 mg/kg	15 mg/kg (up to 750 mg)	75 mg/kg in 24 hr (up to 3,750 mg)

PEDIATRIC DOSE

See comments under Usual Dose.

Management of pain and reduction of fever in pediatric patients 2 to 12 years of age:

15 mg/kg every 6 hours or 12.5 mg/kg every 4 hours. Do not exceed a maximum single dose of 15 mg/kg or a maximum daily dose of 75 mg/kg/day. Minimum dosing interval is 4 hours.

Reduction of fever in infants 29 days to 2 years of age:

15 mg/kg every 6 hours to a maximum daily dose of acetaminophen 60 mg/kg/day, with a minimum dosing interval of 6 hours.

Reduction of fever in neonates, including premature neonates born at 32 weeks or more gestational age, up to 28 days chronologic age:

12.5 mg/kg every 6 hours, to a maximum daily dose of acetaminophen of 50 mg/kg/day, with a minimum dosing interval of 6 hours.

DOSE ADJUSTMENTS

A reduced total daily dose of acetaminophen may be appropriate in patients with hepatic impairment or active liver disease. ■ A reduced total daily dose and longer dosing intervals may be appropriate in patients with a CrCl less than or equal to 30 mL/min.

DILUTION

Available in a single-use vial or bag containing 1,000 mg/100 mL (10 mg/mL) of acetaminophen. For adults and adolescent patients weighing 50 kg or more requiring a 1,000-mg dose, administer the dose by inserting a vented IV set through the septum of the 100-mL vial or a nonvented IV set through the administration spike port of the 100-mL bag. Doses less than 1,000 mg should be withdrawn from the container and placed into a separate empty container before administration to avoid inadvertent administration of an overdose. Withdraw appropriate dose (650 mg or weight-based) from 100-mL vial or bag and place in an empty container (e.g., syringe, glass bottle, plastic IV container) for IV infusion.

Filter:

Information not available.

Storage:

Store unopened vial or bag at CRT. Do not refrigerate or freeze. Do not remove bag from overwrap until ready to use. After removing the outer wrap, check the container for minute leaks by squeezing the solution bag firmly. Discard 6 hours after entry into the container or transfer into an empty container. Single-use product. Discard any unused solution.

COMPATIBILITY

Manufacturer states, “Do not add other medications to solution. **Incompatible** with diazepam and chlorpromazine. Do not administer simultaneously.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as an infusion, equally distributed over 15 minutes. Pediatric doses up to 600 mg may be drawn up into a syringe and delivered via a syringe pump.

ACTIONS

A nonsalicylate antipyretic and a nonopioid analgesic agent. Exact mechanism of action is unknown but is thought to act through central actions. Widely distributed into most tissues except fat. Low protein binding (10% to 25%). Half-life is approximately 2 to 3 hours. Metabolized in the liver via three different pathways. Metabolites excreted in the urine.

INDICATIONS AND USES

Management of mild to moderate pain in adults and pediatric patients 2 years of age and older. ■ Management of moderate to severe pain with adjunctive opioid analgesics in adults and pediatric patients 2 years of age and older. ■ Reduction of fever in adults and pediatric patients.

CONTRAINDICATIONS

Known hypersensitivity to acetaminophen or to any components of the IV formulation. ■ Patients with severe hepatic impairment or severe active liver disease.

PRECAUTIONS

Acetaminophen has been associated with cases of acute liver failure, at times resulting in liver transplant and death. Most cases of liver injury are associated with the use of acetaminophen at doses that exceed the maximum daily limits and often involve more than one acetaminophen-containing product. Do not exceed the maximum recommended daily dose. ■ Use with caution in patients with hepatic impairment or active hepatic disease, alcoholism, chronic malnutrition, severe hypovolemia (e.g., due to dehydration or blood loss), or severe renal impairment (CrCl less than or equal to 30 mL/min). ■ Serious, sometimes fatal, skin reactions such as acute generalized exanthematous pustulosis, Stevens-Johnson syndrome, and toxic epidermal necrolysis have been reported rarely. ■ Hypersensitivity and anaphylactic reactions have been reported. ■ Care must be taken when prescribing, preparing, or administering acetaminophen to avoid dosing errors, which could result in accidental overdose and death; see Usual Dose. ■ Antipyretic effects may mask fever in patients treated for postsurgical pain.

Monitor:

Baseline SCr and liver function tests may be indicated. ■ Monitor for S/S of hypersensitivity reaction (e.g., pruritus; rash; respiratory distress; swelling of the face, mouth, and throat; urticaria). ■ Monitor for S/S of serious skin reactions.

Maternal/Child:

Epidemiologic studies on oral acetaminophen use in pregnant women have not reported a clear association between acetaminophen use and birth defects, miscarriage, or adverse maternal or fetal outcomes. Safety of IV formulation for use in pregnancy not established. Use only if clearly needed. ■ Safety for use in breast-feeding not established. Acetaminophen is secreted in human milk in small quantities after oral administration. Use caution. ■ The effectiveness for treatment of acute pain has not been established in pediatric patients less than 2 years of age. ■ The safety and effectiveness for treatment of fever in pediatric patients, including premature neonates born at 32 weeks or more gestational age, is supported by adequate and well-controlled studies.

Elderly:

No overall differences in safety and efficacy were observed between older and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Substances that induce or regulate hepatic cytochrome enzyme CYP2E1 (e.g., ethanol, isoniazid) may alter the metabolism of acetaminophen and increase its hepatotoxic potential. Effects have not been studied. ■ Chronic acetaminophen doses of 4,000 mg/day may cause an increase in INR in patients stabilized on **warfarin.** Effect of short-term use on INR has not been studied. Monitoring of INR recommended. ■ **Many available analgesics contain acetaminophen in combination with another analgesic** (e.g., hydrocodone/acetaminophen [Vicodin, Norco], oxycodone/acetaminophen [Percocet]). **Over-the-counter cold and allergy preparations and sleep aids** may also contain acetaminophen in combination with other active ingredients. Monitor total daily dose of acetaminophen coming from all possible sources.

SIDE EFFECTS

Adult patients:

The most common adverse reactions were headache, insomnia, nausea, and vomiting. Less frequently reported side effects included anemia, anxiety, dyspnea, fatigue, fever, hypersensitivity reactions including anaphylaxis, hypertension, hypokalemia, hypotension, increased aspartate aminotransferase, infusion site pain, muscle spasms, peripheral edema, and trismus.

Pediatric patients:

The most common adverse reactions were constipation, nausea, pruritus, and vomiting. Less commonly reported side effects included abdominal pain, agitation, anemia, atelectasis, diarrhea, fever, headache, hypersensitivity reaction, hypertension, hypervolemia, hypoalbuminemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, injection site pain, muscle spasm, oliguria, pleural effusion, pulmonary edema, stridor, and wheezing.

Overdose:

Early symptoms may include diaphoresis, general malaise, nausea, and vomiting. More serious adverse effects include hepatic necrosis, renal tubular necrosis, hypoglycemic coma, and thrombocytopenia.

ANTIDOTE

Notify the physician of significant side effects. Discontinue immediately at the first appearance of skin rash or any other sign of hypersensitivity. Treat as indicated (e.g., diphenhydramine, epinephrine, albuterol). Resuscitate as necessary. If an acetaminophen overdose is suspected, obtain a serum acetaminophen level and baseline liver function studies. *N*-acetylcysteine antidote may be indicated. See acetylcysteine monograph. Contact a regional poison control center for additional information.

ACETAZOLAMIDE SODIUM

(ah-set-ah-**ZOE**-la-myd **SO**-dee-um)
Diamox
Antiglaucoma
Anticonvulsant
Diuretic
Urinary alkalinizer
pH 9.2

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Antiglaucoma agent:

250 mg to 1 Gm/24 hr. May be given as 250-mg doses at 4- to 6-hour intervals. In the treatment of secondary glaucoma and in the preoperative treatment of some cases of acute congestive (closed-angle) glaucoma, the preferred dose is 250 mg every 4 hours. In acute cases, to rapidly lower intraocular pressure, an initial single dose of 500 mg followed by 125 to 250 mg at 4-hour intervals may be given.

Edema of congestive heart failure or drug therapy:

250 to 375 mg or 5 mg/kg of body weight as a single dose daily; when loss of edematous fluid stops, reduce to every other day or give for 2 days followed by a day of rest.

Anticonvulsant:

Adults and pediatric patients:

Dose in epilepsy may range from 8 to 30 mg/kg/24 hr in divided doses every 6 to 12 hours (2 to 7.5 mg/kg every 6 hours or 4 to 15 mg/kg every 12 hours). Reduce initial daily dose when given with other anticonvulsants.

Urinary alkalinization:

Adults and pediatric patients:

5 mg/kg/dose every 8 to 12 hours.

PEDIATRIC DOSE

See Maternal/Child.

Acute antiglaucoma agent:

5 to 10 mg/kg every 6 hours. Do not exceed 1,000 mg/24 hr.

Edema of congestive heart failure or drug therapy:

5 mg/kg as a single dose daily or every other day; see comment under Usual Dose. Do not exceed 1,000 mg/24 hr.

Slowly progressive hydrocephalus in infants 2 weeks to 10 months (unlabeled):

20 mg/kg/24 hr in equally divided doses every 8 hours (8.3 mg/kg every 8 hours). Up to 100 mg/kg/24 hr or a maximum dose of 2 Gm/24 hr has been used.

DOSE ADJUSTMENTS

Reduced dose required when introducing acetazolamide into a treatment regimen with other anticonvulsants. ■ Administer every 12 hours in patients with a CrCl from 10 to 50 mL/min. Avoid use in patients with a CrCl less than 10 mL/min (ineffective).

DILUTION

Each 500 mg should be diluted in 5 mL SWFI. May then be given by IV injection or added to standard IV fluids. IM administration not recommended.

Storage:

Reconstituted solution stable for 12 hours at RT or 3 days refrigerated.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

500 mg or fraction thereof over at least 1 minute or added to IV fluids to be given over 4 to 8 hours.

ACTIONS

A potent carbonic anhydrase inhibitor and nonbacteriostatic sulfonamide, acetazolamide depresses the tubular reabsorption of sodium, potassium, and bicarbonate. Excreted unchanged in the urine, producing diuresis, alkalinization of the urine, and a mild degree of metabolic acidosis.

INDICATIONS AND USES

Adjunctive treatment of edema due to congestive heart failure, drug-induced edema, centrencephalic epilepsies (petit mal, unlocalized seizures), chronic simple (open-angle) glaucoma, and secondary glaucoma, and preoperatively in acute angle-closure glaucoma when delay of surgery is desired to lower intraocular pressure. ■ Used orally for acute mountain sickness.

Unlabeled uses:

Metabolic alkalosis, urine alkalinization, respiratory stimulant in COPD.

CONTRAINDICATIONS

Depressed sodium and potassium levels, hyperchloremic acidosis, marked kidney or liver disease, adrenocortical insufficiency, hypersensitivity to acetazolamide or any of its components. Long-term use contraindicated in some glaucomas.

PRECAUTIONS

Chemically related to sulfonamides; may cause serious reactions in sensitive patients. ■ May be alternated with other diuretics to achieve maximum effect. ■ Greater diuretic action is achieved by skipping a day of treatment rather than increasing dose; failure in therapy may be due to overdose or too-frequent dosage. ■ IM administration not recommended. Administration by IV injection is preferred. ■ Use with caution in impaired respiratory function (e.g., pulmonary disease, edema, infection, obstruction); may cause severe respiratory acidosis. ■ Potassium excretion is proportional to diuresis. Hypokalemia may result from diuresis or with severe cirrhosis. ■ Introduce or withdraw gradually when used as an anticonvulsant.

Monitor:

Obtain baseline CBC and platelet count before use and monitor during therapy. ■ Periodic monitoring of electrolytes is recommended.

Patient Education:

Consider birth control options.

Maternal/Child:

Category C: has been shown to be teratogenic in animal studies. Use during pregnancy only if potential benefit justifies potential risks to the fetus. ■ Discontinue breast-feeding or discontinue acetazolamide. ■ Safety for use in pediatric patients not established, but no problems are documented.

Elderly:

Use caution; no documented problems, but age-related renal impairment may be a factor.

DRUG/LAB INTERACTIONS

May cause hypokalemia with concurrent use of **steroids.** ■ Hypokalemia may cause toxicity and fatal cardiac arrhythmias with **digoxin** or interfere with **insulin or oral antidiabetic agent** response, thus causing hyperglycemia. ■ Alkalinization of urine by acetazolamide potentiates **amphetamines, ephedrine, flecainide,**

methenamine, procainamide, pseudoephedrine, quinidine, and tricyclic antidepressants by decreasing rate of excretion. ■ May decrease response to **lithium, methotrexate, some antidepressants, phenobarbital, salicylates, and urinary anti-infectives** by increasing rate of excretion. ■ Metabolic acidosis induced by acetazolamide may potentiate **salicylate** toxicity (anorexia, tachypnea, lethargy, coma, and death can occur with high-dose aspirin). ■ Alkalinity may cause **false-positive urinary protein** and possibly **urinary steroid tests.** ■ May depress **iodine uptake** by the thyroid.

SIDE EFFECTS

Minimal with short-term therapy. Respond to symptomatic treatment or withdrawal of drug: acidosis, anorexia, bone marrow suppression, confusion, crystalluria, drowsiness, fever, hemolytic anemia, hypokalemia (ECG changes, fatigue, muscle weakness, vomiting), paresthesias, photosensitivity, polyuria, rash, renal calculus, thrombocytopenic purpura.

ANTIDOTE

Notify physician of any adverse effects and discontinue drug if necessary. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines. Moderately dialyzable (20% to 40%).

ACETYLCYSTEINE INJECTION

(ah-see-till-**SIS**-tay-een in-**JEK**-shun)
Acetadote
Antidote
pH 6 to 7.5

USUAL DOSE (ADULT AND PEDIATRIC)

Pretreatment assessment and testing after acute acetaminophen ingestion:

- Assess the history and timing of acetaminophen ingestion as an overdose. (The reported history of the quantity ingested is often inaccurate and is not a reliable guide to therapy.)
- Obtain baseline AST, ALT, bilirubin, INR, SCr, BUN, blood glucose, and electrolytes to monitor hepatic and renal function and fluid and electrolyte balance.
- Obtain a plasma or serum sample to assay for acetaminophen concentration at least 4 hours after ingestion. (Levels obtained earlier than 4 hours postingestion may not represent maximum acetaminophen concentration.)
- If the time of the acute acetaminophen ingestion is unknown, administer the loading dose of acetylcysteine immediately and obtain an acetaminophen concentration to determine the need for continued treatment.
- If the acetaminophen concentration cannot be obtained (or is unavailable or

uninterpretable) within the 8-hour time interval after acetaminophen ingestion or if there is clinical evidence of acetaminophen toxicity, administer a loading dose of acetylcysteine immediately and continue treatment for a total of 3 doses over 21 hours.
- If the patient presents more than 8 hours after ingestion and the time of acute acetaminophen ingestion is known, administer a loading dose of acetylcysteine immediately and obtain an acetaminophen concentration to determine the need for continued treatment.
- If the patient presents less than 8 hours after ingestion and both the time of acute acetaminophen ingestion and the acetaminophen concentration are known, use the Rumack-Matthew nomogram to determine whether to initiate treatment with acetylcysteine. Initiation depends on acetaminophen concentration and on the clinical presentation of the patient.

Nomogram for estimating the potential for hepatotoxicity from acute acetaminophen ingestion and the need for acetylcysteine treatment (see prescribing information for nomogram):

Administer a **loading dose** to the following patients:

- Patients whose acetaminophen concentrations are at or above the “possible” toxicity line (dotted line in the nomogram)
- Patients with an acute overdose from an extended-release acetaminophen preparation whose second acetaminophen concentrations (8 to 10 hours postingestion) are at or above the “possible” toxicity line
- Patients whose values are below the “possible” toxicity line, but time of ingestion is unknown or sample was obtained less than 4 hours after ingestion

Continue acetylcysteine treatment (with a **maintenance dose** [total of 3 separate doses over 21 hours]) in the following patients:

- Patients whose acetaminophen concentrations are above the “possible” toxicity line in the nomogram.
- Patients in whom an acetaminophen concentration could not be obtained.
- Patients whose values are below the “possible” toxicity line, but time of ingestion is unknown or sample was obtained less than 4 hours after ingestion. Obtain a second concentration and consider clinical status. If there is any uncertainty regarding patient’s risk of developing hepatotoxicity, it is recommended to administer a complete treatment course.

Recommended dosage in adults and pediatric patients with acute acetaminophen ingestion:

Total dose equals 300 mg/kg given as 3 separate, sequential doses (i.e., 3-bag method to administer the loading, second, and third doses). The total recommended infusion time for the 3 doses is 21 hours. Total volume administered for patients less than 40 kg and for those requiring fluid restriction can be adjusted as clinically needed; see the following dosage charts for patients who weigh from 5 to 20 kg, from 21 to 40 kg, and for patients weighing 41 kg or greater. Consider osmolarity; see Dilution and

Precautions.

Distribute doses as indicated in the following guidelines:

Dosage for patients who weigh 5 to 20 kg:

Loading dose:

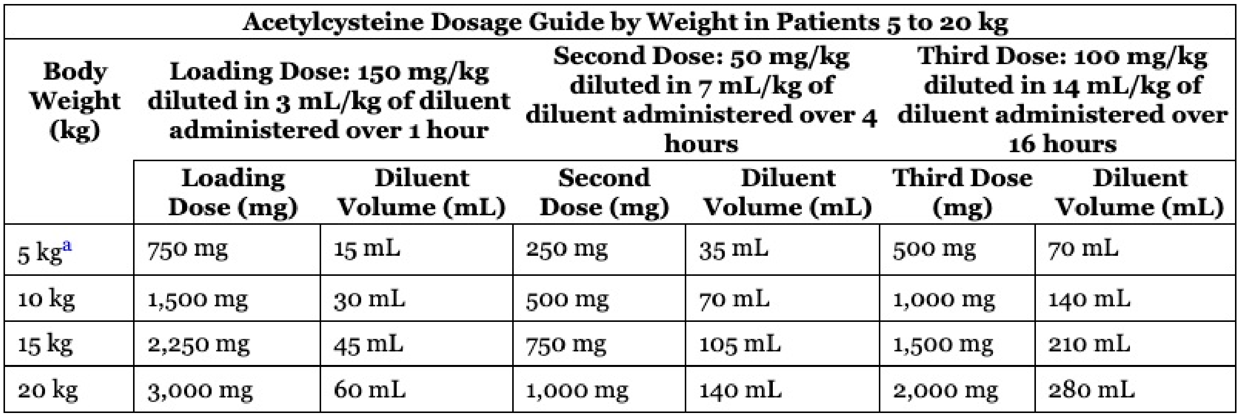
150 mg/kg diluted in 3 mL/kg of diluent administered over 1 hour.

Second dose:

50 mg/kg diluted in 7 mL/kg of diluent administered over 4 hours.

Third dose:

100 mg/kg diluted in 14 mL/kg of diluent administered over 16 hours.



Acetylcysteine Dosage Guide by Weight in Patients 5 to 20 kg

Body Weight (kg)	Loading Dose: 150 mg/kg diluted in 3 mL/kg of diluent administered over 1 hour		Second Dose: 50 mg/kg diluted in 7 mL/kg of diluent administered over 4 hours		Third Dose: 100 mg/kg diluted in 14 mL/kg of diluent administered over 16 hours	
	Loading Dose (mg)	Diluent Volume (mL)	Second Dose (mg)	Diluent Volume (mL)	Third Dose (mg)	Diluent Volume (mL)
5 kg[a]	750 mg	15 mL	250 mg	35 mL	500 mg	70 mL
10 kg	1,500 mg	30 mL	500 mg	70 mL	1,000 mg	140 mL
15 kg	2,250 mg	45 mL	750 mg	105 mL	1,500 mg	210 mL
20 kg	3,000 mg	60 mL	1,000 mg	140 mL	2,000 mg	280 mL

[a] Recommended dosage for patients less than 5 kg has not been studied.

Dosage for patients who weigh 21 to 40 kg:

Loading dose:

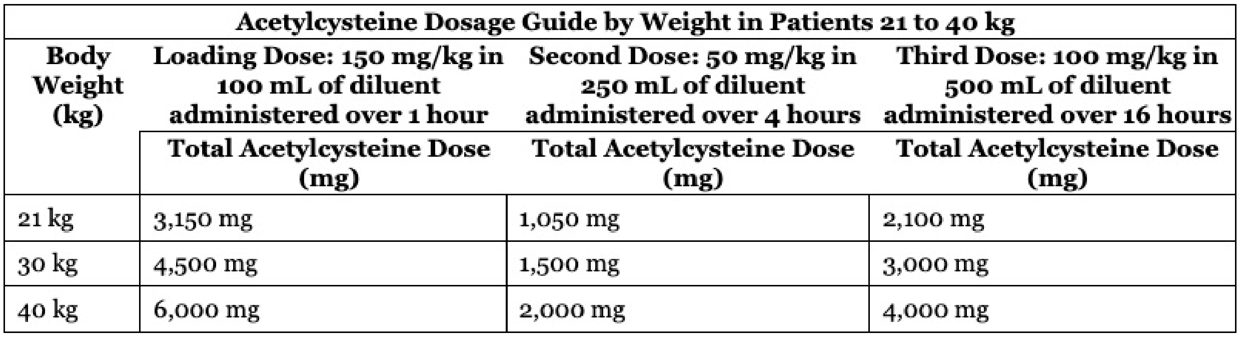
150 mg/kg diluted in 100 mL of diluent administered over 1 hour.

Second dose:

50 mg/kg diluted in 250 mL of diluent administered over 4 hours.

Third dose:

100 mg/kg diluted in 500 mL of diluent administered over 16 hours.



Acetylcysteine Dosage Guide by Weight in Patients 21 to 40 kg

Body Weight (kg)	Loading Dose: 150 mg/kg in 100 mL of diluent administered over 1 hour	Second Dose: 50 mg/kg in 250 mL of diluent administered over 4 hours	Third Dose: 100 mg/kg in 500 mL of diluent administered over 16 hours
	Total Acetylcysteine Dose (mg)	Total Acetylcysteine Dose (mg)	Total Acetylcysteine Dose (mg)
21 kg	3,150 mg	1,050 mg	2,100 mg
30 kg	4,500 mg	1,500 mg	3,000 mg
40 kg	6,000 mg	2,000 mg	4,000 mg

Dosage for patients who weigh 41 kg or greater:

Loading dose:

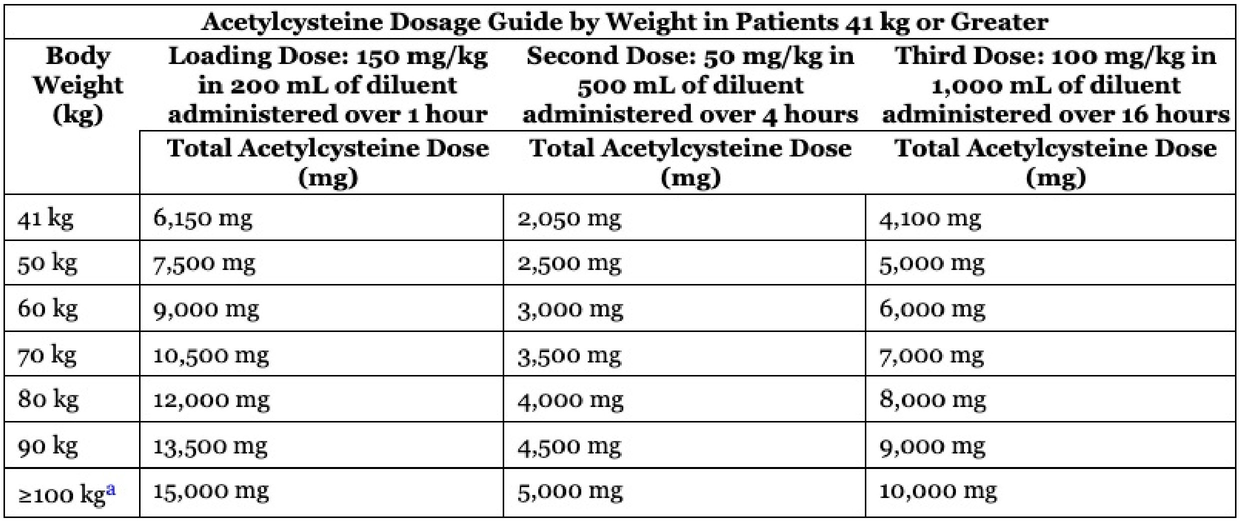
150 mg/kg diluted in 200 mL of diluent administered over 1 hour.

Second dose:

50 mg/kg diluted in 500 mL of diluent administered over 4 hours.

Third dose:

100 mg/kg diluted in 1,000 mL of diluent administered over 16 hours.



Acetylcysteine Dosage Guide by Weight in Patients 41 kg or Greater

Body Weight (kg)	Loading Dose: 150 mg/kg in 200 mL of diluent administered over 1 hour	Second Dose: 50 mg/kg in 500 mL of diluent administered over 4 hours	Third Dose: 100 mg/kg in 1,000 mL of diluent administered over 16 hours
	Total Acetylcysteine Dose (mg)	Total Acetylcysteine Dose (mg)	Total Acetylcysteine Dose (mg)
41 kg	6,150 mg	2,050 mg	4,100 mg
50 kg	7,500 mg	2,500 mg	5,000 mg
60 kg	9,000 mg	3,000 mg	6,000 mg
70 kg	10,500 mg	3,500 mg	7,000 mg
80 kg	12,000 mg	4,000 mg	8,000 mg
90 kg	13,500 mg	4,500 mg	9,000 mg
≥100 kg[a]	15,000 mg	5,000 mg	10,000 mg

[a] No specific studies have been done to evaluate the necessity of dose adjustments in patients weighing over 100 kg. Limited information is available regarding the dosage requirements of patients who weigh more than 100 kg.

DOSE ADJUSTMENTS

Therapy extending beyond 21 hours may be considered in rare cases such as suspected massive overdose, concomitant ingestion of other substances, or in patients with pre-existing liver disease. In these cases, absorption and/or half-life of acetaminophen may be prolonged. Obtain acetaminophen levels and ALT/AST and INR before the end of the 21-hour infusion. If acetaminophen levels are still detectable, or in cases in which ALT/AST is still increasing or INR remains elevated, continue the infusion and contact a regional poison control center. ■ Specific information and/or recommendations are not available for patients with impaired hepatic or renal function.

DILUTION

Available in single-dose vials containing 6 Gm/30 mL. May be diluted in D5W, $^{1}/_{2}$NS, or SWFI. See Usual Dose for dilution guidelines based on weight. Total volume administered should be adjusted for patients less than 40 kg or for those requiring fluid restriction. Hyponatremia and seizures may result from large volumes in small pediatric patients. ■ A hyperosmolar solution. Caution is advised when the diluent volume is decreased; hyperosmolarity of the solution is increased as shown in the following chart.

Acetylcysteine Concentration and Osmolarity			
Acetylcysteine Concentration (mg/mL)	**Osmolarity in ½NS (mOsmol/L)**	**Osmolarity in D5W (mOsmol/L)**	**Osmolarity in SWFI (mOsmol/L)**
7 mg/mL	245 mOsmol/L	343 mOsmol/L	91 mOsmol/L[a]
24 mg/mL	466 mOsmol/L	564 mOsmol/L	312 mOsmol/L

[a] Osmolarity should be adjusted to a physiologically safe level (generally not less than 150 mOsmol/L in pediatric patients).

Color of acetylcysteine may change from colorless to a slight pink or purple once the stopper is punctured; quality is not affected.

Filters:

Data not available and use is not required by manufacturer.

Storage:

Store unopened vials at CRT. Diluted solution is stable for 24 hours at CRT. Do not use previously opened vials for IV administration. Discard unused portions.

COMPATIBILITY

Manufacturer states, “**Compatible** with D5W, ½NS, and SWFI.”

RATE OF ADMINISTRATION

Usual total infusion time of all 3 doses is 21 hours. Rate reduction may be required to manage S/S of infusion reactions; see Monitor and Antidote.

Loading dose:

An infusion evenly distributed over 60 minutes.

Second dose:

An infusion evenly distributed over 4 hours.

Third dose:

An infusion evenly distributed over 16 hours.

ACTIONS

Acetaminophen doses of 150 mg/kg or greater have been associated with hepatotoxicity. Acetylcysteine is an antidote for acetaminophen overdose that protects the liver by maintaining or restoring the glutathione levels (metabolites formed after an overdose of acetaminophen may deplete the hepatic stores of glutathione and cause binding of the metabolite to protein molecules within the hepatocyte, resulting in cellular necrosis). It may also act by forming an alternate substrate and detoxifying the reactive metabolite of acetaminophen. Acetylcysteine is postulated to form cysteine and disulfides. Cysteine is further metabolized to form glutathione and other metabolites. Half-life is approximately 5.6 hours. Crosses the placental barrier. Some excretion in urine.

INDICATIONS AND USES

To prevent or lessen hepatic injury after ingestion of a potentially hepatotoxic quantity of acetaminophen in patients with acute ingestion or repeated supratherapeutic ingestion (RSI).

CONTRAINDICATIONS

Known hypersensitivity to acetylcysteine or any of its components.

PRECAUTIONS

For IV administration only. ■ Should be administered in a facility equipped to monitor the patient and respond to any medical emergency. ■ Most effective against severe hepatic injury when administered within 8 hours of ingestion. Administration before 4 hours does not allow enough time to determine an actual need for treatment with acetylcysteine; serum levels drawn before 4 hours have passed may be misleading. Effectiveness diminishes gradually after 8 hours. Should be administered if 24 hours or less has passed since ingestion, because the reported time of ingestion may not be correct and it does not appear to worsen the patient's condition. ■ Total volume administered should be adjusted for patients less than 40 kg and for patients requiring fluid restriction. If volume is not adjusted, fluid overload can occur, potentially resulting in hyponatremia, seizure, and death; see Usual Dose. ■ Hypersensitivity reactions have been reported and usually occur soon after initiation of the infusion. Use caution in patients with asthma or a history of bronchospasm. Death occurred in a patient with asthma. ■ Acute flushing and erythema of the skin may occur. These reactions usually occur within 30 to 60 minutes of beginning the infusion and often resolve spontaneously despite continued infusion. ■ Clearance decreased and half-life prolonged in patients with various stages of liver damage. ■ The Rumack-Matthew nomogram does not apply to patients with repeated supratherapeutic ingestion (RSI), which is defined as ingestion of acetaminophen at doses higher than those recommended for extended periods of time. For treatment information, see prescribing information for a professional assistance line for acetaminophen overdose, or contact a regional poison control center. ■ The Rumack-Matthew nomogram may underestimate the risk for hepatotoxicity in patients with chronic alcoholism, malnutrition, or CYP2E1 enzyme-inducing drugs (e.g., isoniazid). Consideration should be given to treating these patients even if the acetaminophen concentrations are in the nontoxic range. ■ Vial stopper does not contain natural rubber latex. ■ See Monitor and Antidote.

Monitor:

Obtain baseline AST, ALT, bilirubin, INR, SCr, BUN, blood glucose, and electrolytes to monitor hepatic and renal function and electrolyte and fluid balance. Continue monitoring as indicated.

Preferred method of treatment:

Estimate time of acetaminophen ingestion. If less than 24 hours since overdose, draw an acetaminophen level at 4 hours postingestion or as soon as possible thereafter to clarify the need for intervention with acetylcysteine. The serum acetaminophen level should be evaluated on the Rumack-Matthew nomogram to determine the probability of toxicity (see package insert for copy of nomogram). ■ If serum acetaminophen level is below the treatment line on the nomogram, discontinue the acetylcysteine if initiated as a precaution. If the plasma level is above the treatment line on the nomogram, initiate or continue treatment.

Secondary options for treatment:

If serum acetaminophen levels are not available within 8 hours, initiate treatment. Do not delay treatment more than 8 hours postingestion. ■ If time of ingestion is unknown or if the patient is unreliable, consider empiric initiation of acetylcysteine treatment. ■ If a serum acetaminophen level is not available or cannot be interpreted and less than 24 hours has elapsed since ingestion, administer acetylcysteine regardless of the quantity reported to have been ingested.

All treatment options:

Monitor vital signs before, during, and after the infusion. ■ Evaluate serum acetaminophen level on the Rumack-Matthew nomogram. ■ Infusion reactions may begin with acute flushing and erythema of the skin. May resolve spontaneously despite continued infusion of acetylcysteine or may progress to an acute hypersensitivity reaction and/or anaphylaxis. Observe continuously for initial S/S of a hypersensitivity reaction (e.g., hypotension, rash, shortness of breath, wheezing). ■ In suspected toxicity resulting from the extended-release acetaminophen preparation, an acetaminophen level drawn fewer than 8 hours postingestion may be misleading. Draw a second level at 8 to 10 hours after the acute ingestion. If either acetaminophen level falls above the toxicity line, acetylcysteine treatment should be initiated. ■ See Precautions and Antidote.

Patient Education:

Report S/S of hypersensitivity promptly (e.g., bronchospasm, hypotension, shortness of breath, wheezing).

Maternal/Child:

Use during pregnancy only if clearly needed. Delaying treatment of acetaminophen overdose may increase the risk of maternal or fetal morbidity and mortality. ■ Use caution; safety for use during breast-feeding not established; effects unknown. After 30 hours, acetylcysteine should be cleared from maternal blood, and breast-feeding can be resumed. ■ No adequate or well-controlled studies in pediatric patients; use is based on clinical practice. Efficacy appears to be similar to that seen in adults; see Side Effects.

Elderly:

Differences in response compared with younger adults not known.

DRUG/LAB INTERACTIONS

Drug-drug interaction studies have not been done.

SIDE EFFECTS

Adult and pediatric patients:

Facial flushing, pruritus, rash, and urticaria have been reported most frequently and most commonly occur during the initial loading dose. Other reported side effects include edema, hypersensitivity reactions (including anaphylaxis), hypotension, nausea and vomiting, pharyngitis, respiratory symptoms (e.g., bronchospasm, chest tightness, cough, respiratory distress, shortness of breath, stridor, wheezing), rhinorrhea, rhonchi, tachycardia, and throat tightness.

Overdose:

S/S of acute toxicity in animals included ataxia, convulsions, cyanosis, hypoactivity, labored respiration, and loss of righting reflex.

ANTIDOTE

Keep physician informed of all side effects. Flushing and erythema of the skin may occur and often resolve spontaneously. If other symptoms of a hypersensitivity reaction occur (e.g., bronchospasm, dyspnea, hypotension, wheezing), discontinue acetylcysteine and treat with diphenhydramine or epinephrine as indicated. After symptoms subside, the infusion may be carefully resumed. If S/S of hypersensitivity recur, discontinue infusion permanently and consider alternate treatments. Contact a regional poison control center for possible treatment alternatives. Hemodialysis may remove some acetylcysteine.

ACYCLOVIR

(ay-**SYE**-kloh-veer)
Zovirax
Antiviral
pH 11

USUAL DOSE

Pretreatment:

See Precautions and Monitor.

In all situations for adults, adolescents, children, and neonates, do not exceed a maximum dose of 20 mg/kg every 8 hours.

Adults and adolescents (12 years of age and older):

Herpes simplex infections; mucosal and cutaneous HSV infections in immunocompromised patients:

5 mg/kg of body weight every 8 hours for 7 days.

Severe initial clinical episodes of herpes genitalis:

5 mg/kg every 8 hours for 5 days.

Herpes simplex encephalitis:

10 mg/kg every 8 hours for 10 days.

Herpes zoster infections (shingles) in immunocompromised patients:

10 mg/kg every 8 hours for 7 days.

PEDIATRIC DOSE

Herpes simplex infections; mucosal and cutaneous HSV infections in immunocompromised patients:

Pediatric patients 3 months to 12 years:

10 mg/kg every 8 hours for 7 days.

Herpes simplex encephalitis:

Pediatric patients 3 months to 12 years:

20 mg/kg every 8 hours for 10 days.

Herpes zoster infections (shingles) in immunocompromised patients:

Pediatric patients under 12 years:

20 mg/kg every 8 hours for 7 days.

NEONATAL DOSE

Neonatal herpes simplex virus infections:

PMA of at least 34 weeks:

20 mg/kg every 8 hours for 21 days.

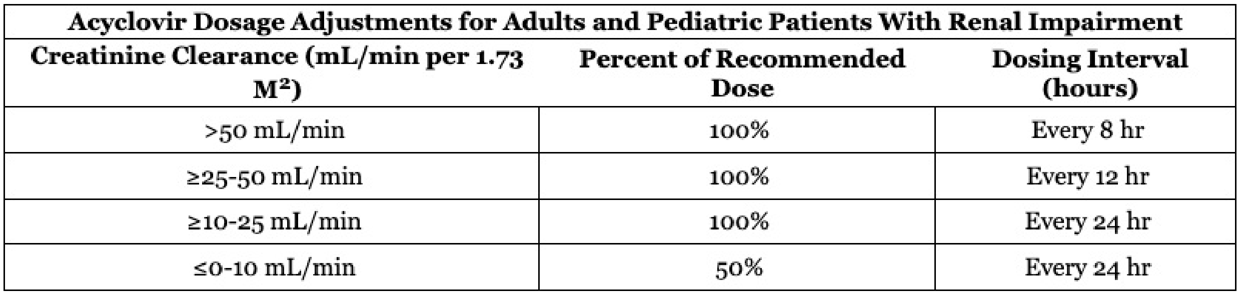
PMA of less than 34 weeks:

20 mg/kg every 12 hours for 21 days.

Doses recommended should be used with caution in neonates with ongoing medical conditions affecting their renal function beyond the effect of prematurity.

DOSE ADJUSTMENTS

Calculate dose by ideal body weight in obese individuals. ■ Reduced dose may be indicated in the elderly based on the potential for decreased renal function and concomitant disease or drug therapy. ■ In adults and pediatric patients (older than 3 months) with impaired renal function, reduce dose and/or adjust dosing interval based on CrCl as indicated in the following chart.



Acyclovir Dosage Adjustments for Adults and Pediatric Patients With Renal Impairment

Creatinine Clearance (mL/min per 1.73 M²)	Percent of Recommended Dose	Dosing Interval (hours)
>50 mL/min	100%	Every 8 hr
≥25-50 mL/min	100%	Every 12 hr
≥10-25 mL/min	100%	Every 24 hr
≤0-10 mL/min	50%	Every 24 hr

Plasma concentrations decrease with hemodialysis; adjustment of the dosing schedule is recommended so that an additional dose is administered after each dialysis. No supplemental dose is indicated in peritoneal dialysis after adjustment of the dosing interval.

DILUTION

Initially dissolve each 500 mg with 10 mL SWFI (1,000 mg with 20 mL). Concentration equals 50 mg/mL. Do not use bacteriostatic water for injection (BWFI); will cause precipitation. Shake well to dissolve completely. Also available in liquid vials. Withdraw the desired dose and further dilute in an amount of solution to provide a concentration less than 7 mg/mL (70-kg adult at 5 mg/kg equals 350 mg dissolved in a total of 100 mL of solution equals 3.5 mg/mL). **Compatible** with most standard electrolyte and glucose infusion solutions.

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at CRT. Use reconstituted solution within 12 hours; high pH may result in etching of glass vial surface after 12 hours. Use solution fully diluted for administration within 24 hours. Manufacturer will supply data showing stability for longer periods under specific conditions.

COMPATIBILITY

Manufacturer lists bacteriostatic water for injection (BWFI) as **incompatible.** Dilution in biologic or colloidal fluids (e.g., blood products, protein solutions) is not recommended.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be administered at a constant rate over 1 hour as an infusion. Renal tubular damage will occur with too-rapid rate of injection. Acyclovir crystals will occlude renal tubules. Use of an infusion pump or microdrip (60 gtt/mL) recommended.

ACTIONS

An antiviral agent with activity against herpes simplex virus types 1 (HSV-1) and 2 (HSV-2) and varicella-zoster virus (VZV). Inhibits replication of viral DNA. Widely distributed in tissues and body fluids. Metabolized to a small extent in the liver. Half-life is approximately 2.5 hours. Excreted mainly as unchanged drug in the urine. Crosses the placental and blood-brain barriers. Secreted in breast milk.

INDICATIONS AND USES

Treatment of initial and recurrent mucosal and cutaneous herpes simplex (HSV-1 and HSV-2) infections in immunosuppressed patients. ■ Severe initial clinical episodes of herpes genitalis in immunocompetent patients. ■ Herpes simplex encephalitis. ■ Neonatal and infant herpes simplex virus infections. ■ Herpes zoster infections (shingles) in immunocompromised patients. ■ Oral acyclovir is used to treat varicella zoster (chickenpox).

Unlabeled uses:

Prevention of HSV reactivation in HSCT, treatment of disseminated HSV or VZV, or empiric treatment of suspected encephalitis in immunocompromised patients with cancer.

CONTRAINDICATIONS

Hypersensitivity to acyclovir or valacyclovir (Valtrex). The ganciclovir monograph indicates a contraindication for ganciclovir with acyclovir.

PRECAUTIONS

Confirm diagnosis of herpes simplex virus (HSV-1 or HSV-2) through laboratory culture. Initiate therapy as quickly as possible after symptoms are identified. ■ For IV use only; avoid IM or SC injection. ■ Use caution in patients with underlying neurologic abnormalities, those with serious renal, hepatic, or electrolyte abnormalities, or significant hypoxia. ■ Use caution in patients receiving interferon or intrathecal methotrexate, or with patients who have had previous neurologic reactions to cytotoxic drugs. ■ Incidence of CNS adverse events may be more common in the elderly or in patients with decreased renal function. ■ Isolates of herpes simplex viruses (HSV-1, HSV-2) and varicella-zoster virus (VZV) with reduced susceptibility to acyclovir have been identified. Consider the possibility of viral resistance to acyclovir in patients who show poor clinical response. ■ Thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS) has been reported in immunocompromised patients receiving acyclovir. Deaths have occurred. ■ See Contraindications.

Monitor:

Maintain adequate hydration and urine flow before and during infusion. Encourage fluid intake of 2 to 3 L/day. ■ Monitor CBC, liver function tests, and renal function; abnormal renal function (decreased CrCl can occur), concomitant use of other nephrotoxic drugs, pre-existing renal disease, and dehydration make further renal impairment with acyclovir more likely. ■ Confirm patency of vein; will cause thrombophlebitis. Rotate site of infusion.

Patient Education:

Maintain adequate hydration. Virus remains dormant and can still spread to others. ■ Avoid sexual intercourse when visible herpes lesions are present. Use condoms routinely.

Maternal/Child:

Use during pregnancy only if benefits outweigh risk to fetus. ■ Breast milk concentrations can be higher than maternal serum concentrations. Discontinue breast-feeding or evaluate very carefully. ■ 10 mg/kg and 20 mg/kg doses in pediatric patients from 3 months to 16 years achieved concentrations similar to those in adults receiving 5 mg/kg to 10 mg/kg. ■ Use with caution in neonates; they have an age-related decrease in clearance and an increase in half-life (3.8 hours).

Elderly:

Effectiveness is similar to younger adults. ■ Plasma concentrations are higher in the elderly compared to younger adults; may be due to age-related changes in renal function. ■ Duration of pain after healing was longer in patients 65 years or older. ■ Incidence of side effects (e.g., CNS adverse events [coma, confusion, hallucinations, somnolence], dizziness, nausea, renal adverse events, vomiting) was increased. ■ See Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

See Precautions. May cause neurotoxicity (e.g., severe drowsiness and lethargy) with **zidovudine.** ■ Concurrent use with other **nephrotoxic agents** (e.g., aminoglycosides [gentamicin, tobramycin], cisplatin) may increase risk of nephrotoxicity, especially in patients with pre-existing renal impairment. ■ Potentiated by **probenecid.** ■ Synergistic effects with **ketoconazole and interferon** have been noted. Clinical importance not established.

SIDE EFFECTS

Acute renal failure, aggressive behavior, agitation, alopecia, angioedema, ataxia, coma, confusion, delirium, diaphoresis, disseminated intravascular coagulation (DIC), dizziness, dysarthria (difficulty articulating words), elevated transaminase levels, encephalopathy, gastrointestinal distress, hallucinations, headache, hematuria, hemolysis, hives, hyperbilirubinemia, hypersensitivity reactions (e.g., anaphylaxis), hypotension, inflammation at injection site, lethargy, leukocytoclastic vasculitis, leukopenia, lymphadenopathy, nausea, obtundation, peripheral edema, phlebitis, photosensitive rash, pruritus, rash, seizures, tissue necrosis, transient increased BUN or SCr levels, tremors, urticaria, vomiting. Some patients (fewer than 1%) may have abdominal pain, anemia, anorexia, anuria, chest pain, diarrhea, edema, fatigue, fever, hemoglobinemia, hepatitis, hypokalemia, ischemia of digits, jaundice, leukocytosis, light-headedness, myalgia, neutropenia, neutrophilia, paresthesia, psychosis, pulmonary edema with cardiac tamponade, rigors, skin reactions (e.g., erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis), thirst, thrombocytosis, thrombocytopenia, visual abnormalities.

ANTIDOTE

Notify physician of all side effects. Discontinue drug with onset of CNS side effects. Treatment will be symptomatic and supportive. Adequate hydration is indicated to prevent precipitation of acyclovir in the renal tubules. A 6-hour session of hemodialysis will reduce plasma acyclovir concentration by approximately 60%. Hemodialysis may be indicated in patients with acute renal failure and anuria. Treat anaphylaxis and resuscitate as necessary.

ADENOSINE

(ah-**DEN**-oh-seen)
Adenocard, Adenoscan
Antiarrhythmic
Diagnostic agent
pH 4.5 to 7.5

USUAL DOSE

Adenocard: Conversion of acute paroxysmal supraventricular tachycardia (PSVT):

6 mg initially as a rapid bolus by the peripheral IV route. If supraventricular tachycardia not eliminated in 1 to 2 minutes, give 12 mg. May repeat 12-mg dose in 1 to 2 minutes if needed. Do not exceed 12 mg in any single dose. Give undiluted directly into a vein. If given into an IV line, use the port closest to the insertion site and follow with a rapid NS flush to be certain the solution reaches the systemic circulation.

Do not administer a repeat dose to patients who develop a high-level block on one dose of adenosine.

Adenoscan: Noninvasive diagnosis of coronary artery disease with thallium tomography:

140 mcg/kg/min (0.14 mg/kg/min) as a 6-minute continuous peripheral infusion (total

dose of 0.84 mg/kg). Injection should be as close to the venous access as possible. Inject thallium at 3 minutes. May be injected directly into adenosine infusion set. Dose should be based on total body weight. There are no data on the safety or efficacy of alternative Adenoscan infusion protocols. Safety and efficacy of Adenoscan administered by the intracoronary route have not been established. ■ See Drug/Lab Interactions.

PEDIATRIC DOSE

See Maternal/Child.

Adenocard: Conversion of acute paroxysmal supraventricular tachycardia (PSVT) in pediatric patients weighing less than 50 kg:

0.05 to 0.1 mg/kg. May increase dose by 0.05 to 0.1 mg/kg increments every 2 minutes until PSVT is terminated or maximum dose is reached (0.3 mg/kg or 12 mg). AHA guidelines recommend 0.1 mg/kg rapid IV push. Follow each dose with a 5- to 10-mL NS flush. Double to 0.2 mg/kg if a second dose is required. Maximum first dose 6 mg. Maximum second dose and maximum single dose is 12 mg. ■ See comments in Usual Dose.

Pediatric patients weighing more than 50 kg:

Same as Usual Dose.

DOSE ADJUSTMENTS

Metabolism of adenosine is independent of hepatic or renal function. No dose adjustment indicated. ■ See Drug/Lab Interactions; alternative therapy (e.g., calcium channel blockers) may be indicated.

DILUTION

Solution must be clear; do not use if discolored or particulate matter present. Give undiluted for both indications.

Storage:

Store at CRT 15° to 30° C (59° to 86° F); refrigeration will cause crystallization. If crystals do form, dissolve by warming to room temperature. Discard unused portion.

COMPATIBILITY

Manufacturer states that thallium-201 is **compatible** with Adenoscan and may be injected directly into the Adenoscan infusion set.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adenocard:

Conversion of acute PSVT:

Must be given as a rapid bolus IV injection over 1 to 2 seconds. Follow each dose with NS flush; see Usual Dose.

Adenoscan:

Pharmacologic stress testing:

See Usual Dose.

ACTIONS

A naturally occurring nucleoside present in all cells of the body. Has many functions. When given as a rapid IV bolus of 6 or 12 mg, adenosine usually has no systemic hemodynamic effects. As a rapid IV bolus, it has antiarrhythmic properties, slowing cardiac conduction (particularly at the AV node), interrupting re-entry pathways through the AV node, and restoring sinus rhythm in patients with PSVT, including PSVT associated with Wolff-Parkinson-White syndrome. When used as a diagnostic aid and given as a continuous infusion, adenosine acts as a vasodilator. Dilates normal coronary vessels, increasing blood flow. Has little effect on stenotic arteries. When administered with thallium-201, helps differentiate between areas of heart supplied by normal blood flow and areas supplied by stenotic coronary arteries. When larger doses are given by infusion, adenosine decreases BP and produces a reflexive increase in HR. Adenocard and Adenoscan have the same molecular structure, same solvent, diluent, and concentration. The difference in their actions is in the rate of administration; however, the FDA has approved Adenocard for converting PSVT and Adenoscan for pharmacologic stress testing. When used for treatment of PSVT, it is effective within 1 minute. When used for diagnostic purposes, maximum effect is reached within 2 to 3 minutes of starting the infusion. Coronary blood flow velocity returns to basal levels within 1 to 2 minutes after the infusion is discontinued. Half-life is estimated to be less than 10 seconds. Adenosine is salvaged immediately by erythrocytes and blood vessel endothelial cells and metabolized for natural uses throughout the body (regulation of coronary and systemic vascular tone, platelet function, lipolysis in fat cells, intracardiac conduction).

INDICATIONS AND USES

Adenocard:

To convert acute paroxysmal supraventricular tachycardia (PSVT) to normal sinus rhythm; a first-line agent according to AHA. Includes PSVT associated with accessory bypass tracts (Wolff-Parkinson-White syndrome). Does not convert atrial flutter, atrial fibrillation, or ventricular tachycardia to normal sinus rhythm (NSR).

Adenoscan:

Adjunct to thallium-201 myocardial perfusion scintigraphy in patients unable to exercise adequately. (Results are similar to exercise stress testing.)

CONTRAINDICATIONS

Known hypersensitivity to adenosine. ■ Sinus node disease, such as symptomatic bradycardia or sick sinus syndrome, and second- or third-degree AV block unless a functioning artificial pacemaker is in place. ■ Known or suspected bronchoconstrictive or bronchospastic lung disease (e.g., asthma).

PRECAUTIONS

Both preparations:

Emergency resuscitation drugs and equipment must always be available. ■ May produce short-lasting first-, second-, or third-degree heart block or sinus bradycardia. Usually self-limiting due to short half-life. Patients who develop high-level block should not be given additional doses of adenosine. ■ May cause dyspnea, bronchoconstriction, and respiratory compromise. Use with caution in patients with obstructive lung disease not associated with bronchoconstriction (e.g., emphysema, bronchitis). Avoid use in patients with bronchoconstrictive or bronchospastic disease (e.g., asthma); see Contraindications.

Adenocard:

Valsalva maneuver may be used before use of adenosine in PSVTs if clinically appropriate. ■ Transient or prolonged episodes of asystole and ventricular fibrillation have been reported. Deaths have occurred. In most instances, these cases were associated with the concomitant use of digoxin and, less frequently, with digoxin and verapamil. ■ Some slowing of ventricular response may occur if atrial flutter or fibrillation is also present.

Adenoscan:

Use with caution in patients with pre-existing first-degree AV block or bundle branch block. ■ Fatal and nonfatal cardiac arrest, sustained ventricular tachycardia (requiring resuscitation), and MI have been reported. Avoid use in patients with S/S of myocardial ischemia (e.g., unstable angina) or cardiovascular instability; may be at increased risk for adverse cardiac events. ■ Can cause significant hypotension. Use with caution in patients with autonomic dysfunction, stenotic valvular heart disease, pericarditis or pericardial effusion, stenotic carotid artery disease with cerebrovascular insufficiency, or uncorrected hypovolemia; may be at increased risk for hypotensive complications. ■ Hemorrhagic and ischemic cerebrovascular accidents have occurred. ■ New onset or recurrence of convulsive seizures has occurred following administration of Adenoscan. Some seizures are prolonged and require emergent anticonvulsive management. Aminophylline may increase the risk of seizures associated with Adenoscan; see Antidote. ■ Hypersensitivity reactions (e.g., chest discomfort, dyspnea, erythema, flushing, throat tightness, and rash) have occurred. ■ Hypertension has been reported; usually resolves spontaneously within several minutes but, in some cases, has lasted for several hours. ■ Atrial fibrillation has been reported. In reported cases, it began 1.5 to 3 minutes into the infusion, lasted for 15 seconds to 6 hours, and spontaneously converted to NSR.

Monitor:

Adenocard: Conversion of acute PSVT:

Must reach systemic circulation; see Usual Dose. ■ ECG monitoring during administration recommended. Monitor BP. At the time of conversion to normal sinus rhythm, PVCs, PACs, atrial fibrillation, sinus bradycardia, sinus tachycardia, skipped beats, and varying degrees of AV nodal block are seen on the ECG in many patients. Usually last only a few seconds and resolve without intervention. ■ Less likely to precipitate hypotension if arrhythmia does not terminate.

Adenoscan: Pharmacologic stress testing:

ECG monitoring during administration recommended. Monitor HR and BP at regular intervals during infusion. ■ Obtain images when infusion complete and redistribution images 3 to 4 hours later. ■ Monitor for S/S of hypersensitivity reactions.

Patient Education:

Avoid consumption of any products containing methylxanthines, including caffeinated coffee, tea, or other caffeinated beverages; caffeine-containing drug products; aminophylline; and theophylline before the myocardial perfusion imaging study. ■ Review medical history (e.g., history of seizures or respiratory compromise). ■ Promptly report any potential side effects.

Maternal/Child:

Category C: use in pregnancy only if clearly needed. Some references recommend avoiding early pregnancy. ■ Safety for use in pediatric patients not established, but has been used for conversion of PSVT in neonates, infants, children, and adolescents. Safety for use in pharmacologic stress testing in patients under 18 years not established. ■ Interrupt nursing after administration of Adenoscan.

Elderly:

Response similar to that seen in younger patients; however, greater sensitivity of some older patients cannot be ruled out. May have diminished cardiac function, nodal dysfunction, concomitant disease, or drug therapy that may alter hemodynamic function and produce severe bradycardia or AV block.

DRUG/LAB INTERACTIONS

Both preparations:

Effects antagonized by **methylxanthines** (e.g., caffeine, theophylline); larger doses may be required or adenosine may not be effective. ■ Potentiated by **dipyridamole**; smaller doses of adenosine may be indicated. Safety and efficacy of adenosine in the presence of dipyridamole have not been systematically evaluated. ■ Cardiovascular effects increased by **nicotine;** rapid injection may induce anginal pain. ■ May produce a higher degree of heart block with **carbamazepine**. ■ Concomitant use with **digoxin alone or digoxin in combination with verapamil** associated with rare cases of ventricular fibrillation; see Precautions. ■ See Usual Dose. ■ **Adenoscan:** Before using Adenoscan for pharmacologic stress testing, avoid (or withhold for at least 5 half-lives) **adenosine antagonists** (e.g., methylxanthines) **and/or potentiators** (e.g., dipyridamole). ■ Has been used with other cardioactive agents such as **beta-adrenergic blockers, angiotensin-converting enzyme inhibitors, and calcium channel blockers** without apparent adverse interactions, but its effectiveness with these agents has not been fully evaluated.

SIDE EFFECTS

Both preparations:

Generally predictable, short lived, and easily tolerated. Most will appear immediately and last less than 1 minute. Atrial fibrillation, bronchospasm, chest pressure or discomfort, dizziness, dyspnea and/or shortness of breath, facial flushing, GI discomfort, headache, hypertension, light-headedness, nausea, numbness, PACs, PVCs, sinus bradycardia, sinus tachycardia, skipped beats, varying degrees of AV nodal block. Less than 1% of patients complain of apprehension; blurred vision; burning; chest pain; head pressure; heavy arms; hyperventilation; hypotension; metallic taste; neck and back pain; palpitations; pressure in groin; seizures; sweating; throat, neck, or jaw discomfort; tight throat; and tingling in arms. Serious side effects may include arrhythmias (persistent), including VT, VF, atrial fibrillation, and torsades de pointes; bronchospasm (severe); myocardial infarction; pulmonary edema; third-degree AV block. Asystole with fatal outcome has been reported.

Post-Marketing:

Both preparations:

Seizure activity, including tonic-clonic (grand mal) seizures, and loss of consciousness. ***Adenoscan:*** Cardiac failure, cerebrovascular accident (including intracranial hemorrhage), fatal and nonfatal cardiac arrest, hypersensitivity reactions, injection site reactions, myocardial infarction, respiratory arrest, throat tightness, ventricular arrhythmia, vomiting. ***Adenocard:*** Atrial fibrillation, bradycardia, prolonged asystole, torsades de pointes, transient increase in blood pressure, VF, VT.

ANTIDOTE

Notify physician of any side effect that lasts more than 1 minute. If a side effect persists, decrease rate of infusion (Adenoscan [pharmacologic stress testing]). Discontinue in any patient who develops severe respiratory difficulties or in any patient who develops persistent or symptomatic high-grade AV block or hypotension. Treat side effects symptomatically if indicated. Bradycardia may be refractory to atropine. Short half-life generally precludes overdose problems, but aminophylline 50 to 125 mg as a slow infusion is a competitive antagonist. Methylxanthine use (e.g., aminophylline) is not recommended in patients who experience seizures in association with Adenoscan. Resuscitate as necessary.

ADO-TRASTUZUMAB EMTANSINE BBW

(a-do-tras-**TU**-zoo-mab em-**TAN**-seen)
Kadcyla

Monoclonal antibody
Antineoplastic
pH 5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting and baseline studies required; see Monitor.

Ado-trastuzumab:

3.6 mg/kg as an infusion every 3 weeks (21-day cycle). ***Do not administer doses greater than 3.6 mg/kg. Do not substitute ado-trastuzumab (Kadcyla) for or with trastuzumab.***

Metastatic breast cancer (MBC):

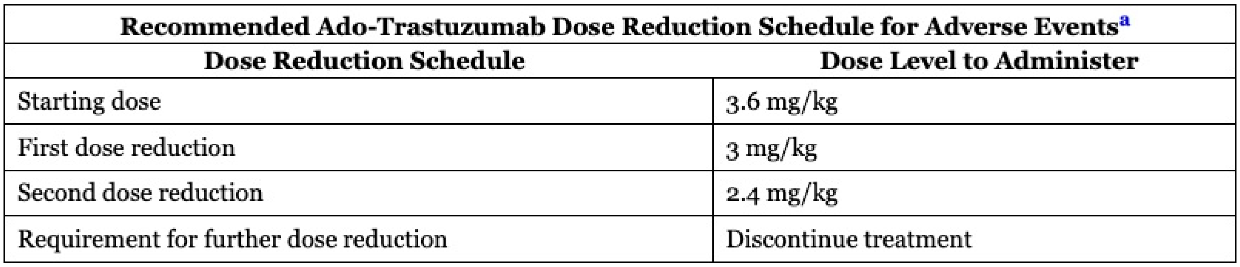
Patients with MBC should receive treatment until disease progression or unmanageable toxicity.

Early breast cancer (EBC):

Patients with EBC should receive treatment for a total of 14 cycles unless there is disease recurrence or unmanageable toxicity.

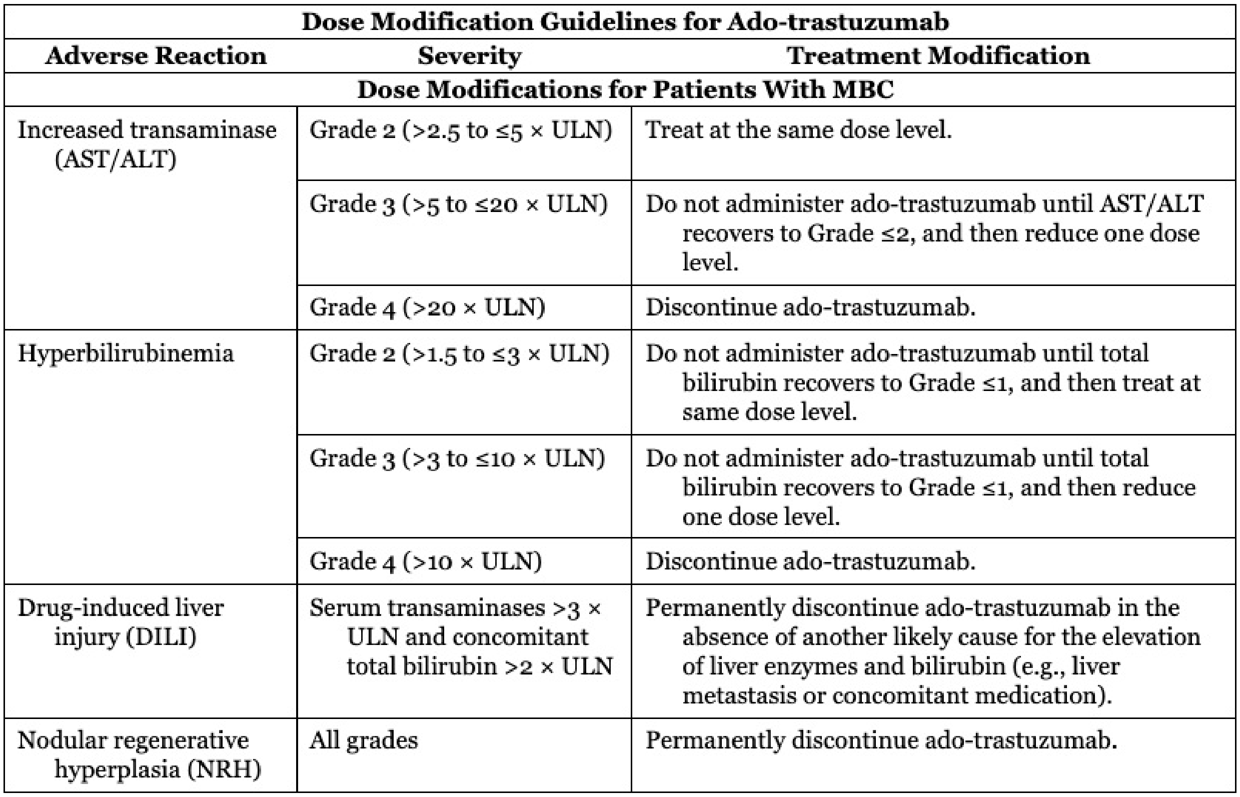
DOSE ADJUSTMENTS

No dose adjustment is indicated in patients with mild or moderate renal impairment. In patients with severe renal impairment (CrCl less than 30 mL/min), no dose adjustments can be recommended because of the limited data available. ■ No dose adjustment is indicated in patients with mild or moderate hepatic impairment. Ado-trastuzumab has not been studied in patients with severe hepatic impairment. ■ Reduce dose or discontinue ado-trastuzumab as outlined in the following charts in cases of increased serum transaminases or total bilirubin. ■ Withhold treatment for clinically significant decrease in left ventricular function as outlined in the following charts. ■ If a planned dose is delayed or missed, ***do not wait until the next planned cycle;*** administer as soon as possible, and adjust the schedule to maintain a 3-week interval between doses. Administer the infusion at the dose and rate the patient tolerated in the most recent infusion. ■ Slow or interrupt the infusion rate if the patient develops an infusion-related reaction; see Rate of Administration and Antidote. ■ The recommended dose reduction schedule for adverse events and dose modification guidelines for various adverse events are listed in the following charts.



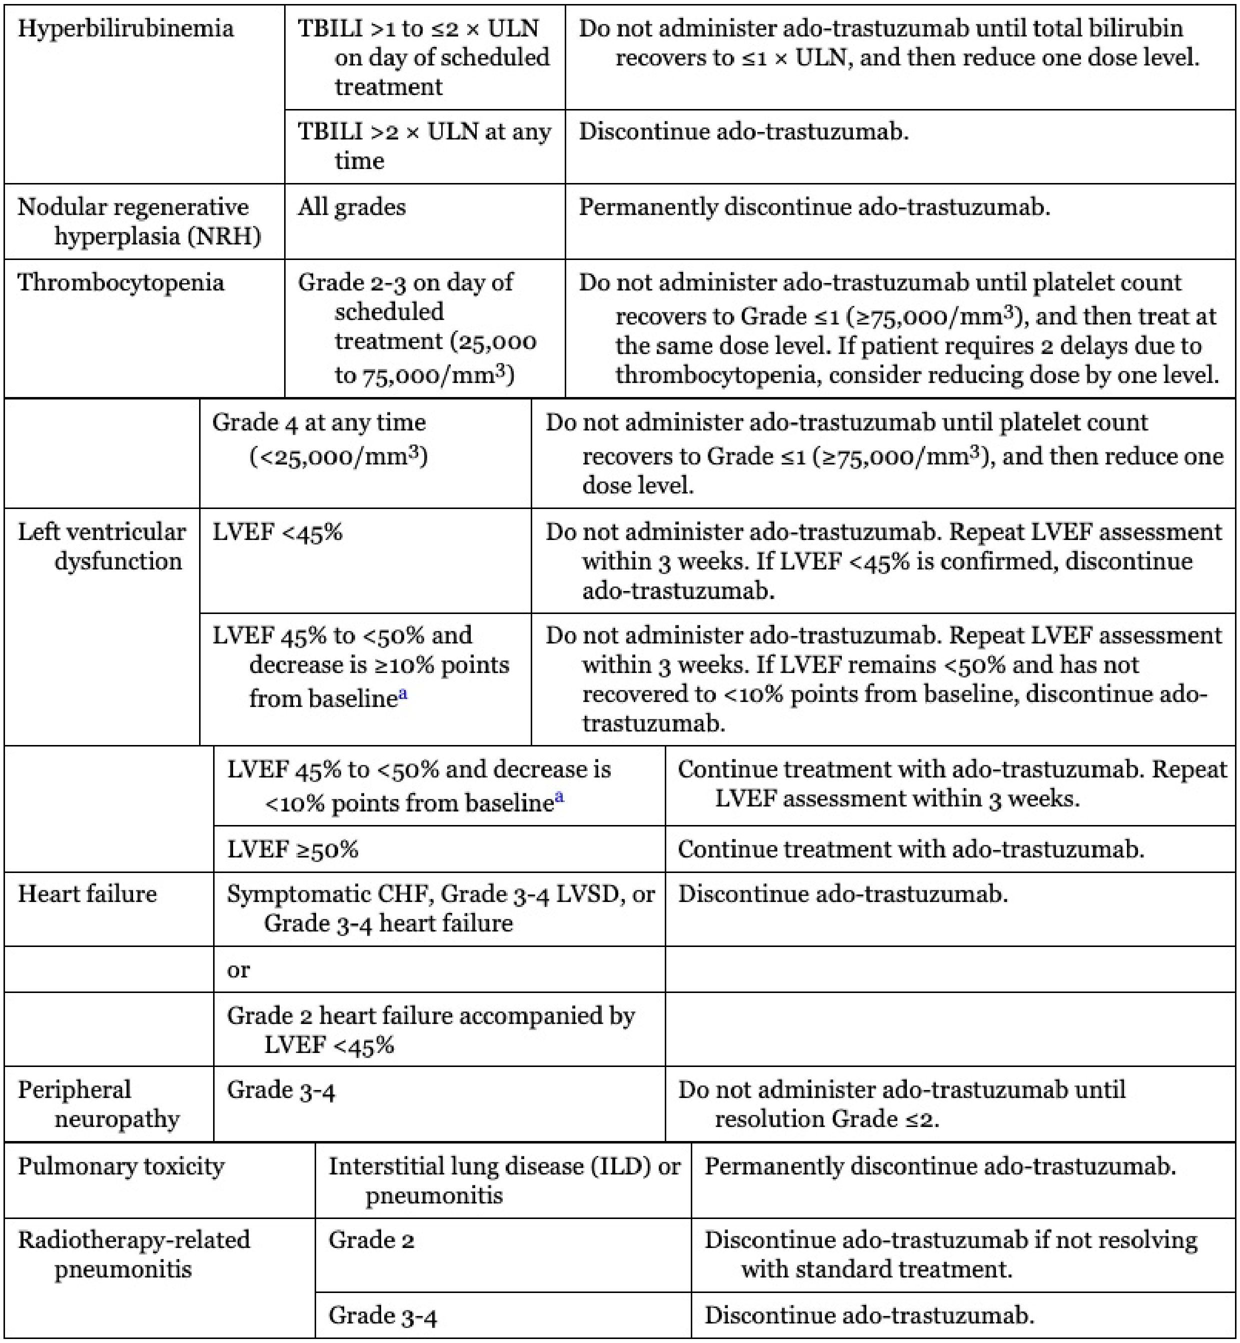
Recommended Ado-Trastuzumab Dose Reduction Schedule for Adverse Events[a]	
Dose Reduction Schedule	**Dose Level to Administer**
Starting dose	3.6 mg/kg
First dose reduction	3 mg/kg
Second dose reduction	2.4 mg/kg
Requirement for further dose reduction	Discontinue treatment

[a] Ado-trastuzumab dose should not be re-escalated after a dose reduction is made.



Dose Modification Guidelines for Ado-trastuzumab		
Adverse Reaction	**Severity**	**Treatment Modification**
Dose Modifications for Patients With MBC		
Increased transaminase (AST/ALT)	Grade 2 (>2.5 to ≤5 × ULN)	Treat at the same dose level.
	Grade 3 (>5 to ≤20 × ULN)	Do not administer ado-trastuzumab until AST/ALT recovers to Grade ≤2, and then reduce one dose level.
	Grade 4 (>20 × ULN)	Discontinue ado-trastuzumab.
Hyperbilirubinemia	Grade 2 (>1.5 to ≤3 × ULN)	Do not administer ado-trastuzumab until total bilirubin recovers to Grade ≤1, and then treat at same dose level.
	Grade 3 (>3 to ≤10 × ULN)	Do not administer ado-trastuzumab until total bilirubin recovers to Grade ≤1, and then reduce one dose level.
	Grade 4 (>10 × ULN)	Discontinue ado-trastuzumab.
Drug-induced liver injury (DILI)	Serum transaminases >3 × ULN and concomitant total bilirubin >2 × ULN	Permanently discontinue ado-trastuzumab in the absence of another likely cause for the elevation of liver enzymes and bilirubin (e.g., liver metastasis or concomitant medication).
Nodular regenerative hyperplasia (NRH)	All grades	Permanently discontinue ado-trastuzumab.

Thrombocytopenia	Grade 3 (25,000 to <50,000/mm^3)	Do not administer ado-trastuzumab until platelet count recovers to Grade ≤1 (≥75,000/mm^3), and then treat at the same dose level.
	Grade 4 (<25,000/mm^3)	Do not administer ado-trastuzumab until platelet count recovers to Grade ≤1 (≥75,000/mm^3), and then reduce one dose level.
Left ventricular dysfunction	Symptomatic CHF	Discontinue ado-trastuzumab.
	LVEF <40%	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF <40% is confirmed, discontinue ado-trastuzumab.
	LVEF 40% to ≤45% and decrease is ≥10% points from baseline	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If the LVEF has not recovered to within 10% points from baseline, discontinue ado-trastuzumab.
	LVEF 40% to ≤45% and decrease is <10% points from baseline	Continue treatment with ado-trastuzumab. Repeat LVEF assessment within 3 weeks.
	LVEF >45%	Continue treatment with ado-trastuzumab.
Pulmonary toxicity	Interstitial lung disease (ILD) or pneumonitis	Permanently discontinue ado-trastuzumab.
Peripheral neuropathy	Grade 3-4	Do not administer ado-trastuzumab until resolution to Grade ≤2.
Dose Modification Guidelines for EBC		
Increased alanine transaminase (ALT)	Grade 2-3 (>3 to ≤20 × ULN on day of scheduled treatment)	Do not administer ado-trastuzumab until ALT recovers to Grade ≤1, and then reduce one dose level.
	Grade 4 (>20 × ULN at any time)	Discontinue ado-trastuzumab.
Increased aspartate transaminase (AST)	Grade 2 (>3 to ≤5 × ULN on day of scheduled treatment)	Do not administer ado-trastuzumab until AST recovers to Grade ≤1, and then treat at the same dose level.
	Grade 3 (>5 to ≤20 × ULN on day of scheduled treatment)	Do not administer ado-trastuzumab until AST recovers to Grade ≤1, and then reduce one dose level.
	Grade 4 (>20 × ULN at any time)	Discontinue ado-trastuzumab.



Hyperbilirubinemia	TBILI >1 to ≤2 × ULN on day of scheduled treatment	Do not administer ado-trastuzumab until total bilirubin recovers to ≤1 × ULN, and then reduce one dose level.
	TBILI >2 × ULN at any time	Discontinue ado-trastuzumab.
Nodular regenerative hyperplasia (NRH)	All grades	Permanently discontinue ado-trastuzumab.
Thrombocytopenia	Grade 2-3 on day of scheduled treatment (25,000 to 75,000/mm^3)	Do not administer ado-trastuzumab until platelet count recovers to Grade ≤1 (≥75,000/mm^3), and then treat at the same dose level. If patient requires 2 delays due to thrombocytopenia, consider reducing dose by one level.
	Grade 4 at any time (<25,000/mm^3)	Do not administer ado-trastuzumab until platelet count recovers to Grade ≤1 (≥75,000/mm^3), and then reduce one dose level.
Left ventricular dysfunction	LVEF <45%	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF <45% is confirmed, discontinue ado-trastuzumab.
	LVEF 45% to <50% and decrease is ≥10% points from baseline[a]	Do not administer ado-trastuzumab. Repeat LVEF assessment within 3 weeks. If LVEF remains <50% and has not recovered to <10% points from baseline, discontinue ado-trastuzumab.
	LVEF 45% to <50% and decrease is <10% points from baseline[a]	Continue treatment with ado-trastuzumab. Repeat LVEF assessment within 3 weeks.
	LVEF ≥50%	Continue treatment with ado-trastuzumab.
Heart failure	Symptomatic CHF, Grade 3-4 LVSD, or Grade 3-4 heart failure	Discontinue ado-trastuzumab.
	or	
	Grade 2 heart failure accompanied by LVEF <45%	
Peripheral neuropathy	Grade 3-4	Do not administer ado-trastuzumab until resolution Grade ≤2.
Pulmonary toxicity	Interstitial lung disease (ILD) or pneumonitis	Permanently discontinue ado-trastuzumab.
Radiotherapy-related pneumonitis	Grade 2	Discontinue ado-trastuzumab if not resolving with standard treatment.
	Grade 3-4	Discontinue ado-trastuzumab.

[a] Prior to starting ado-trastuzumab treatment

DILUTION

Specific techniques required; see Precautions.

Check vial label to avoid medication errors; should read Kadcyla (ado-trastuzumab emtansine), **NOT** trastuzumab. Trade name (Kadcyla) and batch number should be clearly recorded (or stated) in the patient file to improve traceability of biological medicinal products.

Available in single-dose vials of 100 mg/vial and 160 mg/vial. Slowly inject 5 mL of SWFI into the 100-mg vial or 8 mL of SWFI into the 160-mg vial to yield a solution containing 20 mg/mL. Swirl vial gently; ***do not shake***. Solution should be clear to slightly opalescent and colorless to light brown. Withdraw the calculated dose and transfer to an infusion bag of 250 mL of NS. ***Do not use D5W***. Avoid foaming by gently inverting bag to mix. ***Do not shake.*** Immediate use preferred.

Filters:

Use of a 0.2- or 0.22-micron, in-line, polyethersulfone (PES) filter required for administration.

Storage:

Store vials until time of reconstitution in refrigerator at 2° to 8° C (36° to 46° F). ***Do not freeze or shake original vials or reconstituted or diluted solutions***. Reconstituted vials should be used immediately but may be stored for up to 24 hours in a refrigerator at 2° to 8° C (36° to 46° F). Diluted solutions should also be used immediately but can be refrigerated for up to 24 hours. The storage time of the diluted solution is in addition to the time allowed for the reconstituted vials. Discard unused reconstituted or diluted drug after 24 hours.

COMPATIBILITY

Manufacturer states, "Do not mix Kadcyla (ado-trastuzumab emtansine), or administer as an infusion, with other medicinal products." **Incompatible** with D5W.

RATE OF ADMINISTRATION

For IV infusion only. Do not administer as an IV push or bolus. Use of a 0.2- or 0.22-micron, in-line, polyethersulfone (PES) filter required. Slow or interrupt the infusion if patient develops an infusion-related reaction; see Dose Adjustments, Precautions, and Antidote.

First infusion:

Administer over 90 minutes.

Subsequent infusions:

If initial and/or prior infusions are well tolerated, subsequent infusions may be administered over 30 minutes.

Delayed or missed infusions:

Administer at the dose and rate tolerated in the most recent infusion.

ACTIONS

A HER2-targeted antibody-drug conjugate (ADC) that contains the humanized anti-HER2 IgG1, trastuzumab, covalently linked to the microtubule inhibitory drug DM1 (a maytansine derivative). Specific processes result in the intracellular release of DM1-containing cytotoxic catabolites. Binding of DM1 to tubulin disrupts microtubule networks in the cell, which results in cell-cycle arrest and apoptotic cell death. Ado-trastuzumab emtansine also inhibits HER2 receptor signaling, mediates antibody-dependent cell-mediated cytotoxicity, and inhibits shedding of the HER2 extracellular domain in human breast cancer cells that overexpress HER2. Maximum concentrations have been observed close to the end of an infusion. DM1 is metabolized in the liver by CYP3A4/5. Elimination half-life is approximately 4 days.

INDICATIONS AND USES

Used as a single agent in the treatment of patients with HER2-positive, metastatic breast cancer who previously received trastuzumab and a taxane separately or in combination. Patients should have either received prior therapy for metastatic disease or developed a recurrence of disease during or within 6 months of completing adjuvant therapy. ■ Used as a single agent for the adjuvant treatment of patients with HER2-positive early breast cancer who have residual invasive disease after neoadjuvant taxane and trastuzumab-based treatment.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ ***Do not administer doses greater than 3.6 mg/kg.*** ■ ***Do not substitute ado-trastuzumab (Kadcyla) for or with trastuzumab.*** ■ Serious hypersensitivity and/or infusion reactions have occurred. Ado-trastuzumab has not been studied in patients who had trastuzumab permanently discontinued because of infusion-related reactions and/or hypersensitivity; treatment with ado-trastuzumab is not recommended for these patients. ■ Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Exposure to ado-trastuzumab can result in embryo-fetal harm; see Patient Education and Maternal/Child. ■ Hepatotoxicity, predominantly increases in serum transaminases, has been observed. Serious hepatotoxicity has been reported, including liver failure and death. All fatal cases occurred in MBC trials. Comorbidities and/or concomitant hepatotoxic medications were present in some patients. ■ Cases of nodular regenerative hyperplasia (NRH) of the liver have been identified from liver biopsies; one case was fatal. NRH may lead to noncirrhotic portal hypertension. ■ Cardiac toxicity has been reported. Treatment with ado-trastuzumab may lead to reductions in left ventricular ejection fraction (LVEF). Patients with a history of symptomatic CHF, serious cardiac arrhythmia, or a history of MI or unstable angina within 6 months were excluded from trials. ■ Interstitial lung disease (ILD), including pneumonitis, has been reported. Some have resulted in acute respiratory distress syndrome or fatal outcome. Radiation pneumonitis has been reported in patients treated with adjuvant radiotherapy and ado-trastuzumab. Patients with dyspnea at rest due to complications of advanced malignancy and comorbidities and who are receiving concurrent pulmonary radiation may be at increased risk for pulmonary toxicity. ■ Hemorrhagic events, including CNS, respiratory, and GI hemorrhage, have been reported. Some resulted in fatal outcomes. Hemorrhagic events were observed in patients with no known risk factors, as well as in patients with thrombocytopenia and in patients receiving anticoagulation or antiplatelet therapy; see Drug Interactions. ■ Thrombocytopenia has been reported. The incidence and severity of thrombocytopenia were higher in Asian patients. Ado-trastuzumab has not been studied in patients with platelet counts <100,000/mm^3 before initiation of treatment. ■ Peripheral neuropathy (predominantly sensory) has been reported. ■ Effects on patients with severe renal impairment and/or hepatic impairment have not been studied. ■ A protein substance; has potential for immunogenicity. ■ See Dose Adjustments, Monitor, and Antidote.

Monitor:

Verify pregnancy status before beginning ado-trastuzumab therapy. ■ To ensure proper patient selection, assess HER2 status before beginning ado-trastuzumab therapy. Testing should be done by a laboratory with demonstrated proficiency in the testing process. ■ Obtain baseline CBC and differential with platelets before treatment and before each scheduled dose. ■ Obtain baseline AST, ALT, and bilirubin before treatment and before each scheduled dose (every 3 weeks). ■ Obtain baseline LVEF before treatment and at regular intervals (e.g., every 3 months) to confirm it remains within the prescribed parameters. ■ Avoid extravasation; monitor infusion site closely. ■ Monitor for S/S of a hypersensitivity or infusion reaction (e.g., bronchospasm, chills, dyspnea, fever, flushing, hypotension, pruritus, rash, tachycardia, urticaria, and wheezing). Observe closely during and for 90 minutes after the first infusion and during and for at least 30 minutes after subsequent infusions. In most patients, the reaction resolves over the course of several hours to a day after the infusion has been terminated. ■ Consider a possible diagnosis of NRH in patients with clinical symptoms of portal hypertension and/or with cirrhosis-like patterns seen on the computed tomography (CT) scan of the liver but with normal transaminases and no other manifestations of cirrhosis. Diagnosis can be confirmed only by histopathology. ■ Monitor for S/S of ILD (e.g., cough, dyspnea, fatigue, and pulmonary infiltrates). May or may not occur as sequelae of infusion reactions. ■ Monitor for thrombocytopenia (platelet count less than 100,000/mm^3). Nadir occurs by Day 8 and generally improves to Grade 0 or 1 (equal to or greater than 75,000/mm^3) by the next scheduled dose. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood); see Dose Adjustments. ■ Monitor for S/S of peripheral neuropathy (e.g., paresthesias, tingling, weakness).

Patient Education:

Avoid pregnancy; potential serious risk to fetus. Effective contraception required while receiving therapy and for 7 months after the last dose. ■ Male patients with female partners of reproductive potential should use effective contraception during treatment and for 4 months after the last dose of ado-trastuzumab. ■ If ado-trastuzumab is administered during pregnancy or if the patient becomes pregnant within 7 months after the last dose of ado-trastuzumab, the exposure should be reported immediately to the Genentech Adverse Event Line, and the patient should be encouraged to enroll in the pregnancy pharmacovigilance program. ■ Ado-trastuzumab may impair fertility in females and males of reproductive potential. It is not known if the effects are reversible. ■ During infusion, promptly report S/S of an infusion or hypersensitivity reaction (e.g., asthenia, bronchospasm, chills, dizziness, dyspnea, fatigue, fever, flushing, hypotension, nausea, pruritus, rash, urticaria, vomiting, wheezing). ■ Promptly report S/S of acute hepatitis (e.g., abdominal pain, anorexia, dark urine, generalized pruritus, jaundice, nausea, vomiting). ■ Report new-onset or worsening SOB, cough, swelling of ankles/legs, weight gain. ■ See Appendix D.

Maternal/Child:

Avoid pregnancy. Exposure during pregnancy can result in embryo-fetal harm. Oligohydramnios, fatal pulmonary hypoplasia, skeletal abnormalities, and neonatal death have been reported in post-marketing reports for trastuzumab, the antibody component of ado-trastuzumab. DM1, the cytotoxic component of ado-trastuzumab, can cause embryo-fetal toxicity based on its mechanism of action; see Patient Education. ■ Encourage patients who are exposed during pregnancy or within 7 months before conception to enroll in the pregnancy pharmacovigilance program through the manufacturer (Genentech). ■ Discontinue breast-feeding during treatment with ado-trastuzumab and for 7 months after completion of therapy. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety and effectiveness were observed in patients 65 years of age or older compared with younger patients. Age does not affect the pharmacokinetics of ado-trastuzumab.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been done. ■ DM1, the cytotoxic component of ado-trastuzumab, is metabolized mainly by CYP3A4 and to a lesser extent by CYP3A5. **Avoid concomitant use of strong CYP3A4 inhibitors** (e.g., atazanavir [Reyataz], clarithromycin [Biaxin], indinavir [Crixivan], itraconazole [Sporanox], ketoconazole [Nizoral], nefazodone, nelfinavir [Viracept], ritonavir [Norvir], saquinavir [Invirase], telithromycin [Ketek], voriconazole [VFEND]). Consideration of an alternate medication with no or minimal potential to inhibit CYP3A4 is recommended, or delay ado-trastuzumab treatment until the strong CYP3A4 inhibitors have cleared from the circulation (approximately 3 elimination half-lives of the inhibitors). If coadministration cannot be delayed, closely monitor patients for adverse reactions. ■ Possible increased risk of hemorrhage when administered concomitantly with **anticoagulants** (e.g., warfarin [Coumadin]) and/or **antiplatelet agents** (e.g., clopidogrel [Plavix]). Consider additional monitoring when concomitant use is medically necessary.

SIDE EFFECTS

Arthralgia, constipation, epistaxis, fatigue, headache, hemorrhage, increased transaminases, musculoskeletal pain, nausea, peripheral neuropathy, and thrombocytopenia were most common. Serious side effects include embryo-fetal toxicity, hepatotoxicity (including hepatic failure), hypersensitivity and/or infusion-related reactions, left ventricular dysfunction, neurotoxicity, nodular regenerative hyperplasia, portal hypertension, pulmonary toxicity, and thrombocytopenia. Abdominal pain, anemia, arthralgia, asthenia, blurred vision, chills, conjunctivitis, cough, diarrhea, dizziness, dry eyes, dry mouth, dysgeusia, dyspepsia, dyspnea, epistaxis, fever, hypertension, hypokalemia, increased blood alkaline phosphatase, increased bilirubin, increased lacrimation, insomnia, myalgia, neutropenia, peripheral edema, pneumonitis, pruritus, radiation pneumonitis, rash, stomatitis, urinary tract infections, and vomiting have also been reported.

Post-Marketing:

Tumor lysis syndrome.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity or infusion-related reaction. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. See Dose Adjustments for recommendations to reduce dose of, delay, or permanently discontinue ado-trastuzumab in cases of serious side effects. Resuscitate as indicated.

ADUCANUMAB

(a-due-**KAN**-eu-mab)
Aduhelm
Anti-amyloid
Monoclonal antibody
Immune globulin

USUAL DOSE

1 mg/kg once every 4 weeks for 2 infusions, then 3 mg/kg every 4 weeks for 2 infusions, then 6 mg/kg every 4 weeks for 2 infusions, then 10 mg/kg every 4 weeks thereafter.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

DILUTION

Once patient-specific dose is calculated, withdraw the required volume and add to 100 mL of NS. Gently invert to mix ***(do not shake).*** Allow to warm to room temperature if refrigerated.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS.

RATE OF ADMINISTRATION

Administer as an IV infusion over 60 minutes using a 0.22-micron in-line filter.

ACTIONS

Aducanumab reduces amyloid beta plaques; the accumulation of such plaques is the defining characteristic of Alzheimer's disease.

INDICATIONS AND USES

Alzheimer's disease.

CONTRAINDICATIONS

No contraindications listed by manufacturer.

PRECAUTIONS

Amyloid-related imaging abnormalities–edema (ARIA-E) and/or ARIA-hemosiderin deposition may occur within the first 8 doses. If patients experience symptoms such as headache, altered mental status, dizziness, nausea, or visual disturbance, a clinical evaluation must be performed and MRI if indicated. Depending on severity, the drug may need to be discontinued, the dose reduced, or the patient carefully monitored as indicated by physician.

Monitor:

MRI of brain before initiation and before infusion numbers 7 and 12.

Patient Education:

Have patient report symptoms such as headache, altered mental status, dizziness, nausea, or visual disturbance to physician immediately.

Maternal/Child:

No adverse events were observed in animal reproduction studies; however, aducanumab is known to cross the placenta. It is not known if aducanumab is present in breast milk.

Elderly:

Refer to Usual Dose and Precautions.

DRUG/LAB INTERACTIONS

No known significant drug interactions.

SIDE EFFECTS

Hemosiderosis, microhemorrhage, brain edema, falling, headache, diarrhea, altered mental status, confusion, delirium, disorientation, urticaria, angioedema.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

AGALSIDASE BETA

(a-**GAL**-sih-daze **BAY**-tah)
Fabrazyme
Enzyme replenisher

USUAL DOSE

Premedication:

Must be premedicated with acetaminophen and antihistamines (e.g., diphenhydramine) before each dose to prevent or reduce the severity of infusion reactions. The addition of oral steroids (e.g., dexamethasone) may be indicated in patients who have an infusion reaction after initial premedication or in patients with allergenic potential.

Agalsidase beta:

1 mg/kg of body weight as an infusion every 2 weeks.

PEDIATRIC DOSE

Pediatric patients 8 years of age or older:

Same as adult dose.

DOSE ADJUSTMENTS

Patients who have had a positive skin test to agalsidase or who have tested positive for anti-agalsidase IgE may be successfully rechallenged with agalsidase. The initial rechallenge administration should be a low dose at a lower infusion rate (e.g., one-half the therapeutic dose [0.5 mg/kg] at $^1/_{25}$ the initial standard recommended rate [0.01 mg/min]). Once a patient tolerates the infusion, the dose may be increased to reach the approved dose of 1 mg/kg, and the infusion rate may be increased by slowly titrating upward (doubled every 30 minutes up to a maximum rate of 0.25 mg/min) as tolerated. ■ No other dose adjustments indicated.

DILUTION

Available in vials containing 5 or 35 mg of agalsidase. Determine the number of vials needed to provide the calculated dose. Select a combination of 35-mg and 5-mg vials so that the total number of mg is equal to or greater than the patient's number of kg of body weight. Patient weight in kg equals the dose in mg. The number of vials needed is calculated by dividing the weight in kg by 5 or 35 (the number of mg in one vial). For example, an 80-kg patient would receive an 80-mg dose (80 kg × 1 mg/kg = 80 mg). 80 mg divided by 35 mg/vial equals 2.29 vials. Round up to the next whole number, so 3 vials will be required. Alternately, use two 35-mg vials plus two 5-mg vials to achieve 80 mg. Handle vials carefully; avoid shaking or agitation. Before reconstitution, allow vials and diluent to reach room temperature (should take approximately 30 minutes). Reconstitute each 5-mg vial with 1.1 mL of SW (yield equals 5 mg in 1 mL) and each 35-mg vial with 7.2 mL SW (yield equals 35 mg in 7 mL [5 mg/mL]). Do not use filter needles during reconstitution or dilution. Direct diluent down the inside wall of each vial; *do not shake*. Roll and tilt each vial gently to dissolve. Must be further diluted in NS. Withdraw a volume equal to the total calculated volume of agalsidase from an infusion bag of NS as outlined in the following chart. Calculate the total volume by dividing the desired dose by the 5 mg/mL of reconstituted drug (in the previous examples, the 80-mg dose divided by 5 mg/mL yields a volume of 16 mL). Next, slowly withdraw the calculated dose of drug from the reconstituted vials (a total of 16 mL in the previous example) and add it to the NS remaining in the infusion bag. *Must be added into the fluid itself and not into the air space of the infusion bag*.

Normal Saline Volume Required Based on Patient Weight	
Patient Weight (kg)	**Minimum Total Volume of NS (mL)**
≤35 kg	50 mL
35.1 to 70 kg	100 mL
70.1 to 100 kg	250 mL
>100 kg	500 mL

Total volume of the infusion will be 250 mL (16 mL drug and 234 mL NS using the previous example). Use only clear solutions. Gently invert the infusion bag to mix the solution. Avoid vigorous shaking and agitation.

Filters:

Do not use filter needles during reconstitution or dilution. Administer using an in-line, low–protein-binding, 0.2-micron filter.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not use after the expiration date on the vial. Immediate use of reconstituted and diluted solutions is preferred but, if necessary, they may be refrigerated for up to 24 hours. Discard unused reconstituted solution.

COMPATIBILITY

Manufacturer states, "Should not be infused in the same IV line with other products."

RATE OF ADMINISTRATION

Diluted solution filtered through an in-line, low–protein-binding, 0.2-micron filter for administration. Infusion reactions may occur even when patients have been premedicated.

Initial infusion rate:

0.25 mg/min (15 mg/hr) is the maximum initial infusion rate. Should an infusion reaction occur, further decrease this rate or discontinue until symptoms subside. Additional premedication may be indicated. When patient tolerance is well established, the infusion rate with each subsequent infusion may be increased with caution in increments of 0.05 to 0.08 mg/min (increments of 3 to 5 mg/hr).

Patients weighing less than 30 kg:

Maximum infusion rate is 0.25 mg/min (15 mg/hr).

Patients weighing 30 kg or greater:

Minimum infusion duration is 1.5 hours (based on individual patient tolerability).

Patients who have had a positive skin test to agalsidase:

See Dose Adjustments.

ACTIONS

A recombinant form of human alpha-galactosidase A enzyme produced by genetic engineering. Deficiency of alpha-galactosidase A leads to progressive accumulation of glycosphingolipids, predominantly GL-3, in many body tissues (Fabry disease). Agalsidase beta provides an exogenous source of alphagalactosidase A in patients with Fabry disease. It catalyzes the hydrolysis of glycosphingolipids and has been shown to reduce glycosphingolipids, including globotriaosylceramide (GL-3), in renal interstitial capillary endothelial cells. Clinical manifestations of Fabry disease include renal failure, cardiomyopathy, and CVA. Accumulation of GL-3 in renal endothelial cells may play a role in renal failure. Terminal half-life ranges from 45 to 102 minutes and is dose independent.

INDICATIONS AND USES

To reduce globotriaosylceramide (GL-3) deposition in capillary endothelium of the kidney and certain other cell types in patients with Fabry disease.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administered under the direction of a physician knowledgeable in its use and with facilities for monitoring the patient and responding to any medical emergency. ■ Infusion reactions are common, may be severe, and may occur in patients who have been appropriately premedicated. ■ Patients with Fabry disease may have compromised cardiac function and be at increased risk for severe complications from infusion reactions; monitor closely. ■ Is immunogenic (relating to or producing an immune response). Some patients develop IgG antibodies, but clinical significance is not known. Reduction of GL-3 in plasma and GL-3 inclusion in superficial skin capillaries appears to be maintained after antibody formation in study patients. ■ Life-threatening anaphylactic and severe hypersensitivity reactions have been observed in some patients; see Antidote. ■ Some patients may develop IgE antibodies. In patients with suspected allergic reactions, consider testing for IgE and weigh the risks versus benefits of continued treatment. There is no marketed test for antibodies against agalsidase; contact Genzyme Corporation for further information. ■ Reduction of GL-3 in capillary endothelium occurs with treatment, which suggests improvement of disease symptoms; however, the relationship to clinical manifestations of Fabry disease has not been established. ■ Fabry disease is an X-linked genetic disorder and is more common in men than in women. Organ impairment is slower to develop in women than in men.

Monitor:

Monitor V/S frequently. ■ Observe patient continuously for symptoms of infusion reactions (abdominal pain, chest pain, chills, dyspnea, fever, headache, hypertension, hypotension, myalgia, nausea and vomiting, paresthesia, peripheral edema, pruritus, rash, urticaria, and/or tachycardia); see Precautions and Antidote. ■ Numerous other baseline tests and specific monitoring of cardiac, circulatory, and renal function may be indicated based on the degree of progression of each patient's Fabry disease.

Patient Education:

Report early symptoms of an infusion/hypersensitivity reaction promptly (e.g., itching, chest pain, chills, shortness of breath). ■ Report promptly any symptoms that may indicate cardiac or renal problems or stroke (e.g., slow or rapid heart rate, numbness in an extremity, inability to urinate). ■ Genzyme has established a registry and encourages all patients to participate to further evaluate the effects of therapy with possible long-term follow-up.

Maternal/Child:

Use during pregnancy only if clearly needed. Drug-associated risk of major birth defects, miscarriage, or adverse maternal or fetal outcomes has not been identified in post-marketing case reports. ■ No data on the presence of agalsidase beta in either human or animal milk, the effects of the drug on the breast-fed infant, or on milk production. ■ Safety and effectiveness for use in pediatric patients 8 years of age and older has been established. ■ Safety and effectiveness for use in pediatric patients less than 8 years of age not established.

Elderly:

Numbers of elderly were insufficient to determine a difference in response compared to younger adults.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

Infusion reactions are most common and most serious. Other common adverse reactions include abdominal pain, chest pain, chills, cough, dizziness, dyspnea, fatigue, fever, headache, hypertension, hypotension, myalgia, nausea and vomiting, paresthesia, peripheral edema, pruritus, rash, upper respiratory tract infection, urticaria, and/or tachycardia. Ataxia, bradycardia, cardiac arrhythmia, cardiac arrest, decreased cardiac output, hypoacousia (reduced hearing), nephrotic syndrome, pain, and stroke have been reported.

Relationship to agalsidase versus Fabry disease not established.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. If an infusion reaction occurs, reduce rate or discontinue agalsidase until symptoms subside. Additional antipyretics (e.g., acetaminophen), antihistamines (e.g., diphenhydramine), or corticosteroids (e.g., dexamethasone) may be indicated. With additional premedication and/or a reduction in rate of infusion, patients may be able to continue treatment. If a severe hypersensitivity or anaphylactic reaction occurs, discontinue agalsidase immediately and treat as indicated. Resuscitate as necessary.

ALBUMIN (HUMAN)

(al-**BYOO**-min **HU**-man)
Albumin (Human Preservative Free) 5%, 20%, & 25%, Albuminar 5% & 25%, AlbuRx 5% & 25%, Albutein 5% & 25%, Buminate 5% & 25%, Flexbumin 25%, Human Albumin Grifols 25%, Normal Serum Albumin, Plasbumin 5%, 20%, & 25%
Plasma volume expander (plasma protein fraction)
pH 6.4 to 7.4

USUAL DOSE

Variable, depending on patient condition (e.g., presence of hemorrhage, hypovolemia, or shock, pulse, BP, hemoglobin and hematocrit, and amount of pulmonary or venous congestion present). Fluid and protein requirements and underlying condition determine the concentration of albumin used. 5% is usually indicated in hypovolemic or intravascularly depleted patients, and 20% or 25% is appropriate when fluid and sodium intake should be minimized (e.g., cerebral edema, hypoproteinemia, pediatric patients). The initial dose is usually 12.5 to 25 Gm. Amount of 5% given may be increased to 0.5 Gm/lb of body weight (10 mL/lb) with careful monitoring of the patient. Available as 5% solution (5 Gm/100 mL), 20% solution (20 Gm/100 mL), or 25% solution (25 Gm/100 mL). The maximum dose is 6 Gm/kg/24 hr or 250 Gm in 48 hours (250 Gm is equal to 5 L of 5% or 1 L of 25%). In the absence of active hemorrhage, the total dose usually does not exceed the normal circulating mass of albumin (e.g., 2 Gm/kg of body weight).

Hypoproteinemia (hypoalbuminemia):

50 to 75 Gm as a 5% or 25% solution. Repeat doses may be required in patients who continue to lose albumin.

Hypovolemia:

12 to 25 Gm as a 5%, 20%, or 25% solution. May be repeated in 15 to 30 minutes if response inadequate. If 25% solution is used, additional fluids may be needed.

Burns:

Electrolyte replacement and crystalloids (e.g., IV fluids) to maintain plasma volume are required in the first 24 hours. Then begin with 25 Gm and adjust as necessary to maintain albumin level from 2 to 3 Gm/dL.

Acute nephrosis or acute nephrotic syndrome:

20 to 25 Gm of a 25% solution with a loop diuretic (e.g., furosemide [Lasix], torsemide [Demadex]) daily for 7 to 10 days.

Hemodialysis:

100 mL of a 20% or 25% solution.

Red blood cell resuspension:

20 to 25 Gm of a 20% or 25% solution/liter of RBCs.

Cardiopulmonary bypass:

Achieve a plasma albumin of 2.5 Gm/dL and hematocrit concentration of 20% with either a 5% or 25% solution. Use crystalloids (IV fluids) as a pump prime.

PEDIATRIC DOSE

0.5 to 1 Gm/kg/dose. 25% solution is usually used in infants and other pediatric patients; ***do not use in preterm infants.*** Monitor hemodynamic response closely. Maximum dose 6 Gm/kg/24 hr or 250 Gm/48 hr.

Hypoproteinemia (hypoalbuminemia):

0.5 to 1 Gm/kg/dose. Repeat every 1 to 2 days as needed.

Hypovolemia:

0.5 to 1 Gm/kg/dose. May be repeated in 15 to 30 minutes if response inadequate.

Hemolytic disease of the newborn:

1 Gm/kg (4 mL/kg) of 25% albumin. One source recommends giving 1 hour before exchange transfusion. Another recommends 1 to 2 hours before blood transfusion or with transfusion (exchange 50 mL of albumin 25% for 50 mL plasma). ***Do not use in preterm infants.***

Burns:

See Usual Dose.

DILUTION

May be given undiluted or further diluted with NS or D5W for infusion. NS is the preferred diluent. When sodium restriction is required, D5W may be substituted. The use of SWFI as a diluent is not recommended. Life-threatening hemolysis and acute renal failure can result if a sufficient volume of SWFI is used as a diluent. The 5% product is isotonic and osmotically approximates human plasma. One volume of 25% to four volumes of diluent is isotonic. Use only clear solutions.

Storage:

Store at CRT. Use within 4 hours after opening. Discard unused portions.

COMPATIBILITY

Do not use SWFI as a diluent; see Dilution. Manufacturers state, “Do not mix with protein hydrolysates, amino acid mixtures, or solutions containing alcohol.” Manufacturers also state, “May be administered in conjunction with or combined with other parenterals such as whole blood, plasma, glucose, saline, or sodium lactate.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, patient response, and concentration of solution. A too-rapid rate, especially in the presence of normal blood volume, may cause circulatory overload and pulmonary edema. Averages are:

Normal blood volume:

1 to 2 mL/min.

Deficient blood volume (hypovolemia):

A single dose as rapidly as tolerated. Repeat dose as rapidly as tolerated if indicated. As volume approaches normal, slow 5% to 1 to 2 mL/min and 25% to 1 mL/min to prevent circulatory overload and pulmonary edema.

Hypoproteinemia:

2 to 3 mL/min in adults; a single dose over 30 to 120 minutes in pediatric patients.

Infants and other pediatric patients:

For uses other than hypovolemia and hypoproteinemia, the rate of administration should be about one-fourth to one-half the adult rate.

ACTIONS

A sterile natural plasma protein substance prepared by a specific process, which makes it free from the danger of serum hepatitis. A blood volume expander that accounts for

70% to 80% of the colloid oncotic pressure of plasma. Expands blood volume proportionately to amount of circulating blood, improves cardiac output, prevents marked hemoconcentration, aids in reduction of edema, and raises serum protein levels. Low sodium content helps to maintain electrolyte balance and should promote diuresis in presence of edema (contains 130 to 160 mEq sodium/L). Also acts as a transport protein that binds both endogenous and exogenous substances, including bilirubin and certain drugs.

INDICATIONS AND USES

Hypovolemia (with or without shock [actual or impending], with or without hemorrhage); 5% if hypovolemic, 25% if adequate hydration or edema is present. ■ Hypoalbuminemia from inadequate production (e.g., burns, congenital analbuminemia, endocrine disorders, infection, liver disease, major injury, malignancy, malnutrition). ■ Hypoalbuminemia from excessive catabolism (e.g., burns, major injury, nephrosis, pancreatitis, pemphigus [chronic relapsing skin disease], peritonitis, thyrotoxicosis). ■ Hypoalbuminemia from loss from the body (e.g., hemorrhage, burn exudates, excessive renal excretion, exfoliative dermatoses, exudative enteropathy [e.g., inflammatory bowel disease]). ■ Hypoalbuminemia from redistribution within the body (e.g., cirrhosis with ascites, inflammatory conditions, major surgery). ■ Hypoalbuminemia secondary to pulmonary edema in adult respiratory distress syndrome (ARDS). ■ Raising plasma oncotic pressure to treat edema of nephrosis. ■ Cardiopulmonary bypass surgery. ■ Hemolytic disease of the newborn (bilirubin binding activity) as adjunct to exchange transfusion. ■ Provide adequate volume and prevent hypoproteinemia as an adjunct to RBC resuspension.

Unlabeled uses:

Large-volume paracentesis, spontaneous bacterial peritonitis in patients with cirrhosis.

CONTRAINDICATIONS

Anemia (severe) or cardiac failure in the presence of normal or increased intravascular volume, hypersensitivity to albumin, pulmonary edema. ■ Buminate 25% should not be used in patients with chronic renal impairment; contains aluminum.

PRECAUTIONS

Whole blood or packed cells probably indicated if more than 1,000 mL 5% albumin required in hemorrhage; are adjunctive to use of large amounts of serum albumin to prevent anemia. Is not a substitute for whole blood in situations in which both the oxygen-carrying capacity and plasma volume expansion provided by whole blood are required. ■ May be given regardless of patient blood group. ■ Use caution in hypertension, low cardiac reserve, hepatic or renal failure, or lack of albumin deficiency. ■ Use caution in patients with normal or increased intravascular volume; however, patients with hypoproteinemia may have normal blood volume. ■ Use caution in patients with burns, hypoproteinemia, or hypovolemia; an FDA-issued Dear Doctor letter identified concerns of an excess mortality rate when albumin administration was compared to NS administration in these critically ill patients.

Trauma patients with concomitant traumatic brain injuries may also be at risk for increased mortality. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, hepatitis C). Numerous steps in the manufacturing process are used to make the potential for infection extremely remote. ■ 25 Gm of albumin is the osmotic equivalent of 2 units of fresh frozen plasma. 25 Gm of albumin provides as much plasma protein as 500 mL of plasma or 2 units of whole blood. ■ Albumin is not a source of nutrition.

Monitor:

Monitor BP. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are mandatory during therapy. Alkaline phosphatase may be elevated. ■ Hyponatremia may result from administration of large volumes of albumin diluted in D5W; additional monitoring of electrolytes may be required. ■ Observe patient carefully for increased bleeding resulting from more normal BP, circulatory embarrassment, pulmonary edema, or lack of diuresis. Central venous and/or pulmonary wedge pressure readings are most helpful. ■ Maintain hydration with additional fluids, especially in dehydrated patients. ■ Normal plasma albumin is 3.5 to 6 Gm/dL.

Maternal/Child:

Category C: safety for use during pregnancy not established. ■ Do not use 25% solution in preterm infants.

Elderly:

Monitor fluid intake carefully; more susceptible to circulatory overload and pulmonary edema. ■ Plasma albumin levels may be more volatile.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Chills, fever, headache, hypotension, nausea, salivation, skin rash or hives, tachycardia, vomiting.

Major:

Congestive heart failure, decreased myocardial contractility, hypersensitivity reactions including anaphylaxis (rare), precipitous hypotension, pulmonary edema, salt and water retention.

ANTIDOTE

Notify the physician of all side effects. Minor side effects are generally tolerated and treated symptomatically. For major side effects, discontinue albumin and treat symptomatically. Resuscitate as necessary.

ALDESLEUKIN BBW

(al-des-**LOO**-kin)
Interleukin-2 Recombinant, Proleukin
Antineoplastic
Immunomodulator
Biologic response modifier
Recombinant interleukin-2
pH 7.2 to 7.8

USUAL DOSE (International units [IU])

Pretreatment:

Patient selection restricted. Prescreening and baseline studies required; see Precautions/Monitor.

Standard high-dose regimen:

Intermittent IV: 600,000 International units (IU)/kg (0.037 mg/kg) every 8 hours for 14 doses. After 9 days of rest, repeat for up to 14 more doses; this constitutes one course (two 5-day [14 or fewer doses] treatment cycles separated by a rest period of 9 days). Treat with 28 doses or until dose-limiting toxicity requiring ICU-level support occurs. Dose is based on actual patient weight.

Retreatment:

Evaluate for response 4 weeks after course completion and again before scheduling start of the next course. Additional courses are considered if there is some tumor shrinkage following the previous course and retreatment is not contraindicated. At least 7 weeks from hospital discharge should elapse before a subsequent course is administered.

Sometimes given in combination with other agents.

DOSE ADJUSTMENTS

Information on dosing in obese and underweight patients is not available; base dose on actual patient weight. ■ Doses are frequently withheld for toxicity. Doses are actually withheld, not reduced in amount. Median number of doses actually administered in a first course is 20 for metastatic renal cell carcinoma patients and 18 for metastatic melanoma patients. Continuous infusions can be interrupted as indicated by patient symptoms. ■ Hold doses and restart based on the following chart:

Guidelines for Holding Doses of Aldesleukin	
Hold Dose for	**May Give Next Dose if**
CARDIOVASCULAR	
Atrial fibrillation, supraventricular tachycardia, bradycardia that requires treatment or is recurrent or persistent.	Patient is asymptomatic with full recovery to normal sinus rhythm.
Systolic BP <90 mm Hg with increasing requirements for pressors.	Systolic BP ≥90 mm Hg and stable or improving requirements for pressors.
Any ECG change consistent with MI or ischemia with or without chest pain; suspicion of cardiac ischemia or myocarditis.	Patient is asymptomatic; MI and myocarditis have been ruled out; clinical suspicion of angina is low; there is no incidence of ventricular hypokinesia.
PULMONARY	
O_2 saturation <90%.	O_2 saturation >90%.
CENTRAL NERVOUS SYSTEM	
Mental status changes (e.g., agitation, confusion, lethargy, somnolence). May result in coma.	Mental status changes completely resolved.
BODY AS A WHOLE	
Sepsis syndrome; patient is clinically unstable.	Sepsis syndrome has resolved; patient is clinically stable; infection is under treatment.
UROGENITAL	
SCr >4.5 mg/dL or a SCr of ≥4 mg/dL in presence of severe volume overload, acidosis, or hyperkalemia.	SCr <4 mg/dL, and fluid and electrolyte status is stable.
Persistent oliguria, urine output of <10 mL/hr for 16 to 24 hr with rising SCr.	Urine output >10 mL/hr with a decrease of SCr >1.5 mg/dL or normalization of SCr.
DIGESTIVE	
Signs of hepatic failure, including encephalopathy, increasing ascites, liver pain, hypoglycemia.	Discontinue for remainder of current course. May consider a new course of treatment in 7 weeks if all signs of hepatic failure have resolved.
Stool guaiac repeatedly >3 to 4^+.	Stool guaiac negative.
SKIN	
Bullous dermatitis or marked worsening of pre-existing skin condition (avoid topical steroid therapy).	Resolution of all signs of bullous dermatitis.

■ After withholding a dose, no dose should be given until patient is globally assessed and specific criteria for restarting aldesleukin are met.

DILUTION (International units [IU])

Each 22,000,000 IU vial (1.3 mg) must be reconstituted with 1.2 mL of preservative-free SWFI (18,000,000 IU/mL [1.1 mg (1,100 mcg)/mL]). Sterile technique imperative. Direct diluent to side of vial and gently swirl to avoid excess foaming. Do not shake. Further dilute the calculated dose in 50 mL D5W. Desired final infusion concentration is 30 to 70 mcg/mL. If the total dose is 1.5 mg or less (patient weighs less than 40 kg), the dose of aldesleukin should be diluted in a smaller volume of D5W so the final concentration remains in the acceptable range. Plastic infusion containers are preferred over glass. Do not use any filters for dilution or administration. Do not use any other diluent or infusion solution; may cause increased aggregation. Bring to room temperature before administration.

Filters:

Do not use any filters for dilution or administration.

Storage:

Store in refrigerator before and after reconstitution and dilution. Do not freeze. Protect from light. No stability problems will occur at CRT for 48 hours after dilution but has no preservatives. Do not use beyond expiration date on vial.

COMPATIBILITY

Manufacturer recommends not mixing with other drugs in the same container. Bacteriostatic water for injection (BWFI) or NS will increase aggregation.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent IV:

A single dose as an intermittent infusion over 15 minutes. Flush main line IV with D5W before and after each use. Manufacturer recommends that any keep-open IV in place for intermittent administration be D5W.

ACTIONS

A genetically engineered recombinant protein that possesses the biologic activity of naturally occurring interleukin-2. Exact mechanism of action is unknown. Immunoregulatory properties include enhancement of lymphocyte mitogenesis and stimulation of long-term growth of human interleukin-2 dependent cell lines, enhancement of lymphocyte cytotoxicity, induction of killer cell (lymphokine-activated [LAK] and natural [NK]) activity, and induction of interferon-gamma production. Immunologic effects occur in a dose-dependent manner and include activation of cellular immunity with profound lymphocytosis, eosinophilia, and thrombocytopenia, as well as the production of cytokines, including tumor necrosis factor, IL-1, and gamma interferon. Half-life is approximately 85 minutes. Eliminated by metabolism in the kidney with little or no bioactive protein excreted in urine.

INDICATIONS AND USES

Prescreening mandatory. Eligibility requirements for treatment are specific; see Precautions and Contraindications. ■ Treatment of metastatic renal cell carcinoma in adults. Patient selection should include assessment of performance status. See prescribing information for details. ■ Treatment of adults with metastatic melanoma.

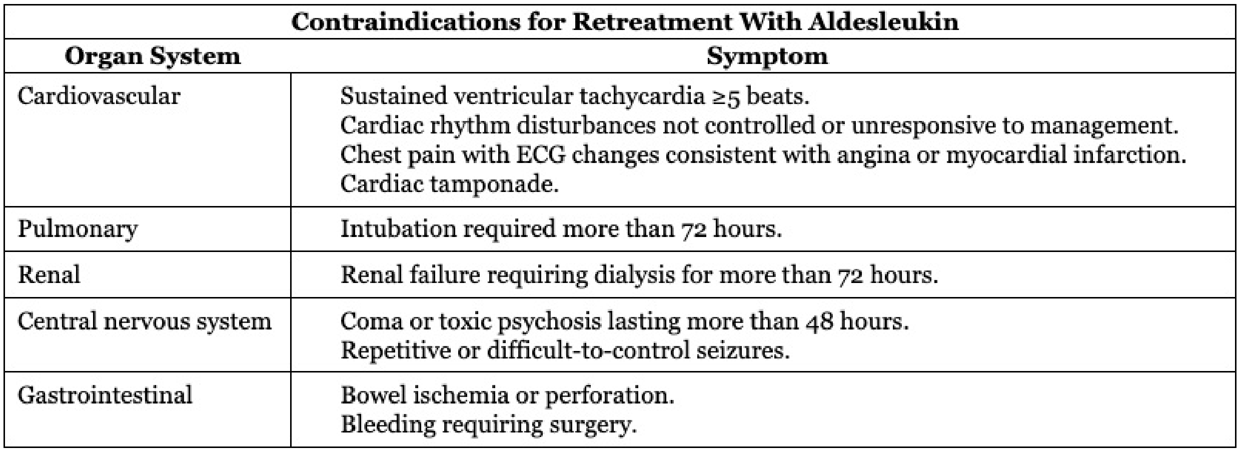
Unlabeled uses:

Acute myelogenous leukemia after autologous BMT.

CONTRAINDICATIONS

Abnormal thallium stress test or pulmonary function tests. ■ Known hypersensitivity to interleukin-2 or any component of aldesleukin. ■ Patients with organ allografts. ■ Exclude from treatment any patient with significant cardiac, pulmonary, renal, hepatic, or CNS impairment; any patient requiring treatment with steroidal agents; and any patient at higher risk for cardiovascular adverse events during periods of hypotension and fluid shifts.

Retreatment is permanently contraindicated in patients who experienced specific toxicities in a previous course of therapy (see the following chart).



Contraindications for Retreatment With Aldesleukin

Organ System	Symptom
Cardiovascular	Sustained ventricular tachycardia ≥5 beats. Cardiac rhythm disturbances not controlled or unresponsive to management. Chest pain with ECG changes consistent with angina or myocardial infarction. Cardiac tamponade.
Pulmonary	Intubation required more than 72 hours.
Renal	Renal failure requiring dialysis for more than 72 hours.
Central nervous system	Coma or toxic psychosis lasting more than 48 hours. Repetitive or difficult-to-control seizures.
Gastrointestinal	Bowel ischemia or perforation. Bleeding requiring surgery.

PRECAUTIONS

Administered in the hospital under the supervision of a qualified physician (usually a medical oncologist and/or immunologist). Intensive care facilities and specialists in cardiopulmonary and/or intensive care medicine must be available. ■ Capillary leak syndrome (CLS [extravasation of plasma proteins and fluid into the extravascular space and loss of vascular tone]) can begin immediately after aldesleukin treatment starts and results in hypotension and reduced organ perfusion that can be severe enough to result in death. CLS may be associated with angina, arrhythmias (supraventricular and ventricular), edema, GI bleed or infarction, mental status changes, myocardial infarction, renal insufficiency, and respiratory insufficiency requiring intubation. Extravasation of protein and fluid into the extravascular space will lead to edema and the creation of new effusions. ■ Therapy should be restricted to patients with normal cardiac and pulmonary functions as defined by appropriate tests. ■ Use extreme caution in patients with normal thallium stress tests and pulmonary function tests who have a history of prior cardiac or pulmonary disease. ■ Patients who have had a nephrectomy are eligible for treatment if SCr is less than 1.5 mg/dL (85% of patients in one study). ■ Mental status changes (e.g., irritability, confusion, depression) may be indicators of bacteremia or early bacterial sepsis, hypoperfusion, occult CNS malignancy, or direct aldesleukin-induced CNS toxicity. Mental status changes due solely to aldesleukin may progress for several days before recovery begins. Permanent neurologic deficits have been reported. ■ Withhold administration in patients who develop moderate to severe lethargy or somnolence; continued administration may result in coma. ■ May exacerbate disease symptoms in clinically unrecognized or untreated CNS metastases. Thoroughly evaluate and treat CNS metastases before aldesleukin therapy. New neurologic signs, symptoms, and anatomic lesions have been reported in patients without evidence of CNS metastases. Clinical manifestations include agitation, ataxia, change in mental status, hallucinations, obtundation, speech difficulties, and coma. Cortical lesions and demyelination have been seen using MRI studies. Neurologic S/S usually resolve following discontinuation of therapy; however, there have been reports of permanent damage. ■ Use extreme caution in patients with a history of seizures (may cause seizures), patients with fixed requirements for large volumes of fluid (e.g., hypercalcemia), those with autoimmune disorders (e.g., Crohn's disease, ulcerative colitis, psoriasis), previous cytotoxic drug therapy or radiation therapy, and patients sensitive to *Escherichia coli*–derived proteins. ■ May cause autoimmune disease and inflammatory disorders or exacerbate pre-existing conditions. ■ Serious manifestations of eosinophilia involving eosinophilic infiltration of cardiac and pulmonary tissues can occur following aldesleukin administration. ■ Associated with impaired neutrophil function and an increased risk of disseminated infection, including sepsis and bacterial endocarditis. Pre-existing bacterial infections should be adequately treated before beginning therapy. Patients with indwelling central lines are at increased risk for infection with gram-positive organisms. Antibiotic prophylaxis with ciprofloxacin, nafcillin, or vancomycin has been associated with a reduced incidence of staphylococcal infections. ■ Induces significant hypotension; discontinue antihypertensives during treatment. ■ Kidney and liver function are impaired during aldesleukin therapy. ■ May impair thyroid function; changes may suggest autoimmunity; thyroid replacement therapy has been required in a few patients. ■ May cause hyperglycemia and/or diabetes mellitus. ■ Anti-aldesleukin antibodies have been detected in some patients. Impact of antibody formation on efficacy and safety of aldesleukin is unknown. ■ See Drug/Lab Interactions.

Monitor:

A central venous catheter (double or triple lumen) is frequently ordered on admission (required for continuous infusion). A minimum of two IV lines is usually required (one for the aldesleukin and its keep-open IV and one for other needed fluids and medications). Flushing of line with D5W before and after aldesleukin is imperative. Ability to record CVP and draw blood samples should be available. ■ Admission chest x-ray, ECG, CBC with differential and platelet count, blood chemistries including electrolytes and renal and liver function tests, T_3, T_4, PT, PTT, urinalysis, and body weight should be obtained. Adequate pulmonary function, normal arterial blood gases, and normal ejection fraction should be documented. ■ During drug administration obtain daily CBC with differential and platelet count, blood chemistries including electrolytes, renal and hepatic function tests, and chest x-rays. ■ Continuous cardiac monitoring is indicated (required with BP below 90 mm Hg or any cardiac irregularity). ■ Monitoring and flexibility in management of fluid balance and organ perfusion status are imperative. Requires constant management and balancing of effects of fluid shifts to prevent the consequences of hypovolemia (e.g., impaired organ perfusion) or fluid accumulation (e.g., edema, pulmonary edema, ascites, pulmonary effusion), which may exceed the patient's tolerance. ■ Assess hypovolemia by central venous catheterization and frequent central venous pressure monitoring. Administer colloids (albumin, plasmanate) or crystalloids (IV fluids) as indicated for a BP drop of 20 mm Hg or greater or a systolic BP less than 90. ■ Frequent neuro checks required (note agitation, blurred vision, confusion, depression, irritability, and persistent somnolence). ■ Vital signs and strict I&O are required every 2 to 4 hours (much more frequently as side effects develop). ■ Weigh daily. ■ Assess thyroid function periodically. ■ An ECG and cardiac enzymes are indicated for any S/S of chest pain, murmurs, gallops, irregular rhythm, or palpitations. A repeat thallium study is indicated for evidence of cardiac ischemia or CHF; may indicate ventricular hypokinesia due to MI or myocarditis. ■ Obtain a urinalysis as indicated. ■ Assess pulmonary function through examination, vital signs, and pulse oximetry. Arterial blood gases are indicated for any dyspnea or respiratory impairment. ■ If fever occurs several days into treatment or recurs after subsiding, assume infection first, then drug. Confusion, depression, or irritability may also suggest infection. Draw cultures; administer appropriate antibiotics. ■ Patients who have had nephrectomies may be more at risk for increases in serum BUN or creatinine, electrolyte shifts, and reduced urine output. Evaluate fluid, electrolyte, and acid-base status promptly if any of the above occur. Gradual increases without other complications (marked fluid overload, hyperkalemia, acidosis) are frequently tolerated (SCr must not exceed 4.5 mg/dL). ■ Maintain pulmonary status as needed with O_2 and diuretics. Assess pulmonary status with chest x-rays. ■ Monitor central and peripheral IV sites to reduce potential for infection. ■ No restrictions on activity; use caution ambulating (orthostatic hypotension). ■ No restrictions on diet. Encouragement may be required (anorexia and/or mouth sores). ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Specific preparation required for discharge; refer to literature. ■ Manufacturer supplies excellent brochures for nurses and physicians with detailed guidelines in chart form on all aspects of monitoring, toxicity, and treatment. ■ Complete review and adequate preparation of all aspects of this therapy with the patient and family are imperative. Can reduce psychological stress of toxicity. ■ Tumor regression has continued for up to 12 months after one or more courses of therapy. ■ See Dose Adjustments, Contraindications, and Antidote.

Patient Education:

Many side effects will occur; report any changes you perceive so they can be evaluated and treated if needed (e.g., changes in breathing, chest or other pain, temperature, mood, light-headedness, fatigue). ■ Request assistance for ambulation and always sit on the side of the bed first. ■ Take only prescribed medications. ■ Avoid alcohol. ■ Use of effective contraceptive measures recommended for fertile men and women. ■ Use 15 SPF sunscreen in sunlight to protect against photosensitivity. ■ See Appendix D, p. 1311, for additional information. ■ Manufacturer supplies a patient education booklet; review thoroughly and discuss with your physician and nurse.

Maternal/Child:

Category C: benefits must outweigh risks. Contraceptive measures required before initial administration and throughout treatment. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients under 18 years of age not established; studies show responsiveness and toxicity similar.

Elderly:

Response rates and toxicity similar to that seen in younger adults; however, some increased incidence of severe urogenital toxicities and dyspnea was noted in the elderly. ■ Use caution; consider age-related organ impairment.

DRUG/LAB INTERACTIONS

May cause interactions with **psychotropic drugs** (e.g., analgesics, antiemetics, narcotics, sedatives, tranquilizers) because aldesleukin also affects central nervous function. ■ Concomitant use with **cardiotoxic agents** (e.g., doxorubicin [Adriamycin]), **hepatotoxic agents** (e.g., methotrexate, asparaginase), **myelotoxic agents** (e.g., cytotoxic chemotherapy, radiation therapy), **and nephrotoxic agents** (e.g., aminoglycosides, indomethacin) may increase toxicity in these organ systems and/or delay excretion of these agents, increasing their toxicity. ■ Acute, atypical adverse reactions have been reported in patients treated with aldesleukin and subsequently administered **radiographic iodinated contrast media.** Reactions have included chills, diarrhea, edema, fever, hypotension, nausea, oliguria, pruritus, rash, and vomiting. Most reactions were reported when contrast media were given within 4 weeks after the last dose of aldesleukin. ■ **Glucocorticoids** (e.g., dexamethasone) reduce aldesleukin-induced side effects but also reduce its antitumor effectiveness. ■ Aldesleukin-induced hypotension may be potentiated by **beta-blockers and other antihypertensive agents** (e.g., ACE inhibitors, calcium channel blockers). ■ Concurrent use with **interferon-alfa** may increase incidence of MI, myocarditis, ventricular hypokinesia, and severe rhabdomyolysis. ■ May cause hypersensitivity reactions in patients receiving combination regimens **(high-dose aldesleukin and antineoplastics)**. ■ Aldesleukin may decrease clearance and increase plasma levels of **indinavir**. ■ Capable of altering numerous lab values; see literature.

SIDE EFFECTS

Frequent, predictable, often severe; are usually clinically manageable and frequently require intensive care management. Begin to occur shortly after therapy begins (chills, fatigue, fever, hypotension, nausea, vomiting). Frequency and severity are dose-related and schedule-dependent. Most are reversible within 2 or 3 days of discontinuation of therapy. Even with intensive management, side effects can progress to death.

Initially anorexia, arthralgia, chills, fatigue, fever, nausea, and vomiting occur. Initial symptoms of capillary leak syndrome are edema, electrolyte abnormalities, hypotension, oliguria, respiratory distress, significant weight gain, tachycardia. Effects of CLS

successively result in ***hypovolemia,*** which in turn leads to hypotension → hypoperfusion → sinus tachycardia → angina → myocardial ischemia and infarction → arrhythmias (supraventricular and ventricular) → decreased renal perfusion → prerenal azotemia → oliguria → anuria; ***fluid retention/weight gain,*** which in turn leads to rales → dyspnea → cough → tachypnea → hypoxia → pleural effusion → respiratory insufficiency requiring intubation → diarrhea → edema of the bowel → refractory acidosis → edema → ascites; and ***breakdown of blood-brain barrier*** (neuropsychiatric toxicity [e.g., agitation, combativeness, confusion, hallucinations, lethargy, psychosis, somnolence]). Abdominal pain and GI bleeding may be related to diarrhea, vomiting, stomatitis, duodenal ulcer formation, bowel ischemia, infarction, or perforation. Cerebral edema and concomitant medications may impact many side effects. Lethargy and/or somnolence may lead to coma. Anemia and thrombocytopenia may occur; coagulation abnormalities (PT, PTT) reflect liver dysfunction. Hemodynamic effects similar to septic shock may be caused by tumor necrosis factor. Erythematous rash and pruritus (can progress to dry desquamation) can occur in almost all patients and are extremely uncomfortable. See Precautions and Drug/Lab Interactions.

Post-Marketing:

Anaphylaxis, angioedema, cardiac tamponade, cardiomyopathy, cellulitis, cerebral hemorrhage, cerebral lesions, cholecystitis, colitis, demyelinating neuropathy, encephalopathy, eosinophilia, extrapyramidal syndrome, fatal endocarditis, fatal subdural and subarachnoid hemorrhage, febrile neutropenia, gastritis, hepatitis, hepatosplenomegaly, hypertension, hyperthyroidism, injection site necrosis, insomnia, intestinal obstruction, lymphocytopenia, myopathy, myositis, neuralgia, neuritis, neutropenia, pneumonia (bacterial, fungal, viral), retroperitoneal hemorrhage, rhabdomyolysis, urticaria.

ANTIDOTE

Temporarily discontinue aldesleukin and notify physician immediately of arrhythmias or rhythm changes, chest pain, marked changes in HR, positive neuropsychiatric check (agitation, blurred vision, persistent extreme somnolence), systolic BP below 90 mm Hg, apical HR over 120, temperature over 38° C (100.4° F), respirations over 25/min, complaints of dyspnea, decreased breath sounds, increased sputum production, severe diarrhea associated with refractory acidosis, vomiting refractory to treatment, acute changes in GI status. May be restarted based on patient response. Hold any subsequent dose for failure to maintain organ perfusion; see Dose Adjustments. Fever is routinely treated with acetaminophen and indomethacin or naprosyn; increased doses may be needed. Suggested treatments include slow IV meperidine for chills and rigidity; diphenoxylate or loperamide PO for diarrhea; diphenhydramine 25 mg PO q 6 hr, a soothing skin cream, and oatmeal baths for urticaria and pruritus; temazepam for insomnia; ondansetron for nausea. Treat edema with furosemide once BP has normalized. IV fluids, albumin or plasmanate, and Trendelenburg positioning are used to maintain fluid balance and BP. If organ perfusion and BP are not sustained by dopamine 1 to 5 mcg/kg/min as a continuous infusion, increase to 6 to 10 mcg/kg/min or add phenylephrine (1 to 5 mcg/kg/min). Prolonged use of pressors at relatively high doses may cause cardiac arrhythmias. Treat arrhythmias as indicated (usually sinus or supraventricular tachycardia [adenosine, verapamil]). Use O_2 for decreased PaO_2. Use packed RBCs for anemia and to ensure maximum oxygen-carrying capacity. Platelet transfusions are indicated for thrombocytopenia or to reduce risk of GI bleeding. Use of blood modifiers to treat bone marrow toxicity may be indicated. Special precautions may be required (e.g., avoid IM injections; test urine, emesis, stool, secretions for occult blood). All treatment is supportive; recovery should begin within a few hours of cessation of aldesleukin. With normalized BP, diuretics (furosemide) can hasten recovery. Low-dose haloperidol may help severe mental status changes.

More rapid onset of dose-limiting toxicities will occur with overdose. **Dexamethasone** is indicated to counteract life-threatening toxicities. May result in loss of therapeutic effect.

ALEMTUZUMAB BBW

(**ah**-lem-**TOOZ**-uh-mab)
Campath ■ Lemtrada
Monoclonal Antibody
Antineoplastic
Immunomodulator
pH 6.8 to 7.4

USUAL DOSE

Campath

Pretreatment:

Verify pregnancy status; baseline studies indicated; see Monitor and Maternal/Child.

Premedication, dose escalation to the recommended maintenance dose, and anti-infective prophylaxis are required.

Premedication:

Diphenhydramine 50 mg and acetaminophen 500 to 1,000 mg should be administered 30 minutes before the first dose, at dose escalations, and as clinically indicated. For cases in which severe infusion-related reactions have occurred, corticosteroids may be administered to help prevent or minimize subsequent reactions.

Dose escalation:

Dose escalation is required at initiation of therapy or if dosing is held for 7 or more days during treatment. Initiate at a dose of 3 mg daily. When this dose is tolerated (infusion-related toxicities are Grade 2 or less), the daily dose should be increased to 10 mg. When the 10-mg dose is tolerated, the maintenance dose of 30 mg may be initiated. In most cases, dose escalation to the maintenance dose of 30 mg can be achieved in 3 to 7 days.

Maintenance dose:

30 mg/day administered three times a week on alternate days (e.g., Monday, Wednesday, Friday). Total duration of therapy, including dose escalation, is 12 weeks.

Single doses greater than 30 mg or cumulative weekly doses greater than 90 mg have been associated with an increased incidence of pancytopenia and should ***not*** be administered.

Anti-infective prophylaxis:

Administer sulfamethoxazole/trimethoprim DS twice daily three times a week (or equivalent) as *Pneumocystis jiroveci* pneumonia (PCP) prophylaxis and famciclovir (Famvir) 250 mg twice daily or equivalent as herpetic prophylaxis at the start of alemtuzumab therapy. Continue PCP and herpes viral prophylaxis for a minimum of 2 months after completion of therapy or until the CD4+ count is equal to or greater than 200 cells/mm^3, whichever occurs later.

Lemtrada

Pretreatment:

Verify pregnancy status. Pretesting required and baseline studies indicated; see Precautions and Monitor. Before starting treatment with Lemtrada:

- Complete any necessary immunizations at least 6 weeks before treatment with Lemtrada.
- Determine whether the patient has a history of varicella or has been vaccinated for varicella zoster virus (VZV). If not, test the patient for antibodies to VZV and consider vaccination if antibody-negative. Postpone treatment until 6 weeks after VZV vaccination.
- Perform tuberculosis screening according to local guidelines.
- Instruct patients to avoid potential sources of *Listeria monocytogenes*.

Premedication:

Corticosteroids:

Administer high-dose corticosteroids (1,000 mg methylprednisolone [Solu-Medrol] or equivalent) immediately before Lemtrada infusion for the first 3 days of each treatment course. Also consider pretreatment with antihistamines and/or antipyretics.

Herpes prophylaxis:

Administer antiviral prophylaxis for herpetic viral infections starting on the first day of each treatment course and continue for a minimum of 2 months following treatment with Lemtrada or until the CD4+ lymphocyte count is at least 200 cells/µL, whichever occurs later.

Lemtrada:

Recommended dose is 12 mg/day administered by IV infusion for 2 treatment courses.

First treatment course:

12 mg/day as an infusion on 5 consecutive days (60 mg total dose).

Second treatment course:

12 mg/day as an infusion on 3 consecutive days (36 mg total dose) administered 12 months after the first treatment course.

Subsequent treatment courses:

After the second treatment course, subsequent treatment courses of 12 mg/day on 3 consecutive days (36 mg total dose) may be administered as needed at least 12 months after the last dose of any prior treatment courses.

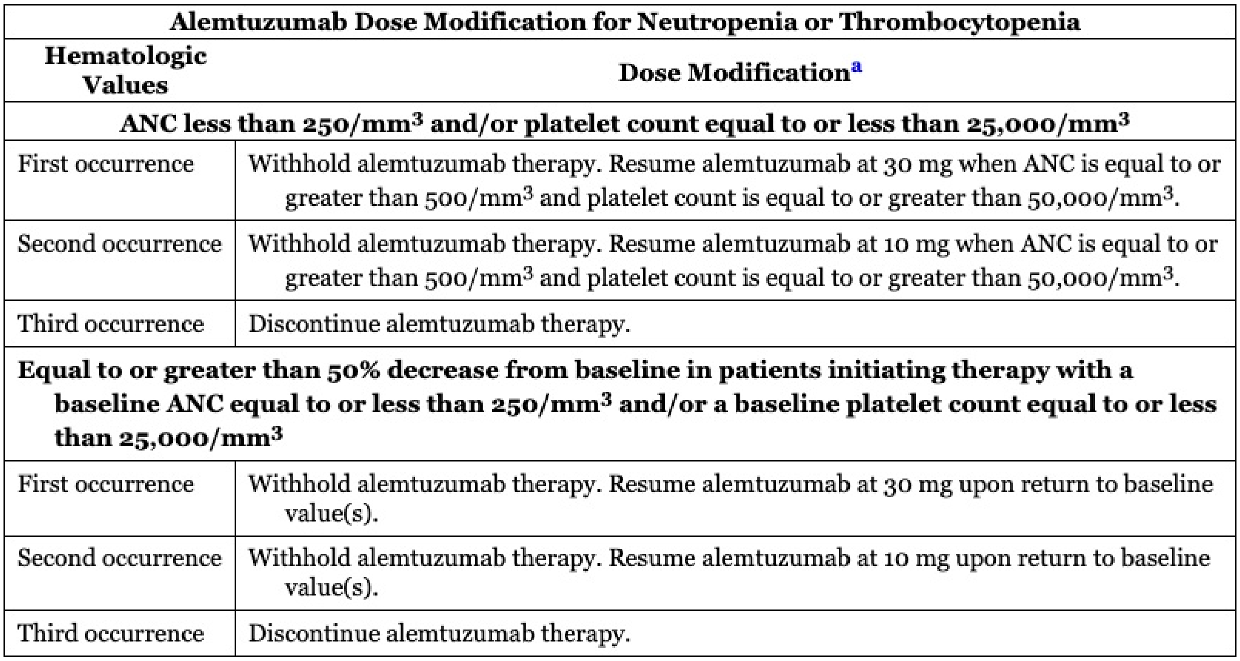
DOSE ADJUSTMENTS

Campath and Lemtrada

Withhold alemtuzumab during serious infections or other serious adverse reactions until resolution.

Campath

There are no dose modifications recommended for lymphopenia. ■ Discontinue alemtuzumab for autoimmune anemia or autoimmune thrombocytopenia. ■ Recommendations for dose modification for severe neutropenia or thrombocytopenia are listed in the following chart.



<table>
<tr><th colspan="2">Alemtuzumab Dose Modification for Neutropenia or Thrombocytopenia</th></tr>
<tr><th>Hematologic Values</th><th>Dose Modification[a]</th></tr>
<tr><th colspan="2">ANC less than 250/mm^3 and/or platelet count equal to or less than 25,000/mm^3</th></tr>
<tr><td>First occurrence</td><td>Withhold alemtuzumab therapy. Resume alemtuzumab at 30 mg when ANC is equal to or greater than 500/mm^3 and platelet count is equal to or greater than 50,000/mm^3.</td></tr>
<tr><td>Second occurrence</td><td>Withhold alemtuzumab therapy. Resume alemtuzumab at 10 mg when ANC is equal to or greater than 500/mm^3 and platelet count is equal to or greater than 50,000/mm^3.</td></tr>
<tr><td>Third occurrence</td><td>Discontinue alemtuzumab therapy.</td></tr>
<tr><th colspan="2">Equal to or greater than 50% decrease from baseline in patients initiating therapy with a baseline ANC equal to or less than 250/mm^3 and/or a baseline platelet count equal to or less than 25,000/mm^3</th></tr>
<tr><td>First occurrence</td><td>Withhold alemtuzumab therapy. Resume alemtuzumab at 30 mg upon return to baseline value(s).</td></tr>
<tr><td>Second occurrence</td><td>Withhold alemtuzumab therapy. Resume alemtuzumab at 10 mg upon return to baseline value(s).</td></tr>
<tr><td>Third occurrence</td><td>Discontinue alemtuzumab therapy.</td></tr>
</table>

[a] If the delay between dosing is equal to or more than 7 days, resume alemtuzumab therapy at 3 mg and escalate to 10 mg and then to 30 mg as tolerated; see Usual Dose and Rate of Administration.

DILUTION

Campath

Available as a 30 mg/1 mL single-use vial. ***Do not shake*** vial before use. Contains no preservatives; sterile technique is imperative. Withdraw the necessary amount of Campath from the vial into a syringe:

- To prepare the 3-mg dose, withdraw 0.1 mL into a 1-mL syringe calibrated in increments of 0.01 mL.
- To prepare the 10-mg dose, withdraw 0.33 mL into a 1-mL syringe calibrated in increments of 0.01 mL.
- To prepare the 30-mg dose, withdraw 1 mL in either a 1-mL or 3-mL syringe calibrated in 0.1-mL increments.

Inject the appropriate dose into 100 mL of NS or D5W. Gently invert the bag to mix solution. Discard any unused drug.

Lemtrada

Available as a 12 mg/1.2 mL single-use vial. ***Do not freeze or shake*** vial before use. Contains no preservatives; sterile technique is imperative. Withdraw 1.2 mL of Lemtrada from the vial into a syringe and inject into 100 mL of NS or D5W. Gently invert the bag to mix solution.

Filters:

Specific information not available.

Storage:

Campath:

Store vials in refrigerator at 2° to 8° C (36° to 46° F). ***Do not freeze or shake***. If accidentally frozen, thaw at 2° to 8° C before administration. Protect from direct sunlight.

Lemtrada:

Store vials in refrigerator at 2° to 8° C (36° to 46° F) in original carton to protect from light. ***Do not freeze or shake.***

Campath and Lemtrada:

Prepared solution may be stored at RT (15° to 25° C [Lemtrada] or 15° to 30° C [Campath]) or refrigerated. Protect from light and use within 8 hours of dilution.

COMPATIBILITY

Campath and Lemtrada:

Manufacturer states, "Do not add or simultaneously infuse other drug substances through the same intravenous line."

Campath:

Compatible with PVC bags and PVC or polyethylene-lined PVC administration sets.

RATE OF ADMINISTRATION

Campath and Lemtrada:

Do not administer as an IV push or bolus.

Campath:

A single dose as an infusion over 2 hours. Subcutaneous administration is unlabeled but has been used.

Lemtrada:

A single dose as an infusion over 4 hours starting within 8 hours of dilution. Extend duration of infusion if clinically indicated.

ACTIONS

A recombinant, DNA-derived, humanized monoclonal antibody (Campath-1H) that binds to the 21-28 kD cell surface glycoprotein, CD52. CD52 is expressed on the surface of both normal and malignant B- and T-lymphocytes, natural killer (NK) cells, most monocytes, macrophages, and a subpopulation of granulocytes. A proportion of bone marrow cells, including some CD34+ cells, also express variable levels of CD52.

The proposed mechanism of action for **Campath** is antibody-dependent cellular-mediated lysis following cell surface binding of Campath to the leukemic cells. The precise mechanism of action by which **Lemtrada** exerts its therapeutic effects in multiple sclerosis is unknown but is presumed to involve binding to CD52. Following cell surface binding to T- and B-lymphocytes, **Lemtrada** results in antibody-dependent cellular cytolysis and complement-mediated lysis. Circulating T- and B-lymphocytes are depleted after each treatment course. Lymphocyte counts then increase slowly over time, with B-cell counts recovering within 6 months and T-cell counts recovering after 12 months. Alemtuzumab exhibits nonlinear kinetics. **Campath** AUC and half-life increase with repeated dosing. Mean half-life was 11 hours (range 2 to 32 hours) after the first 30-mg dose and was 6 days (range 1 to 14 days) after the last 30-mg dose. The half-life of **Lemtrada** was approximately 2 weeks and was comparable between courses.

INDICATIONS AND USES

Campath

As a single agent for treatment of B-cell chronic lymphocytic leukemia (B-CLL).

Lemtrada

Treatment of patients with relapsing forms of multiple sclerosis (MS). Because of its safety profile, use is generally reserved for patients who have had an inadequate response to two or more drugs indicated for the treatment of MS.

CONTRAINDICATIONS

Campath

Manufacturer states, “None.”

Lemtrada

Contraindicated in patients who are infected with human immunodeficiency virus (HIV) because it causes prolonged reductions of CD4+ lymphocyte counts.

PRECAUTIONS

Campath and Lemtrada

Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor patient and respond to any medical emergency. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Campath

Serious and, in rare instances, fatal pancytopenia/marrow hypoplasia, autoimmune idiopathic thrombocytopenia, and autoimmune hemolytic anemia have been reported. Have occurred at recommended dose. Myelosuppression may be prolonged. Do not exceed maximum daily or weekly recommended dose. See Usual Dose, Dose Adjustments, and Antidote. ■ Campath treatment results in severe and prolonged lymphopenia with a concomitant increased incidence of opportunistic infections. Serious and sometimes fatal bacterial, viral, fungal, and protozoan infections have been reported. Prophylaxis directed against *Pneumocystis jiroveci* pneumonia and herpes virus infections is recommended. Prophylaxis has been shown to decrease but not eliminate the occurrence of these infections. See Usual Dose, Dose Adjustments, Monitor, and Antidote. ■ Serious and sometimes fatal infusion reactions can occur; see Monitor. ■ Administer only irradiated blood products to avoid transfusion-associated graft-versus-host disease (TAGVHD) unless immediate transfusion is required.

Lemtrada

Available only through the Lemtrada REMS program because of the risks of autoimmunity, infusion reactions, and malignancies; see prescribing information. ■ Treatment with Lemtrada can result in the formation of autoantibodies and increase the risk of serious autoimmune-mediated conditions. May cause serious, sometimes fatal, autoimmune conditions such as immune thrombocytopenia and antiglomerular basement membrane disease. Several other autoimmune disorders have also been reported in a small number of patients. ■ Immune thrombocytopenia (ITP) has occurred and has been diagnosed more than 3 years after the last Lemtrada dose. Antiplatelet antibodies did not precede ITP onset. ■ Glomerular nephropathies (e.g., membranous glomerulonephritis, antiglomerular basement membrane [anti-GBM] disease) have occurred, and some resulted in ESRD requiring dialysis or renal transplantation. May occur up to 40 months after the last dose of Lemtrada. ■ Newly diagnosed autoimmune thyroid disorders (e.g., Graves' disease, hyperthyroidism, hypothyroidism, autoimmune thyroiditis, goiter) have been reported and have occurred more than 7 years after the first Lemtrada dose. Thyroidectomy was required in some patients. In patients with ongoing thyroid disorder, consider benefit versus risk of Lemtrada administration. ■ Autoimmune cytopenias (e.g., neutropenia, hemolytic anemia, pancytopenia) have occurred. Prompt medical attention is indicated if a cytopenia is confirmed. ■ Causes cytokine release syndrome, which may result in serious and life-threatening infusion reactions. ■ Cases of pulmonary alveolar hemorrhage with an onset of within 48 hours of the Lemtrada infusion have been reported in post-marketing use. ■ May cause an increased risk of malignancies, including thyroid cancer, melanoma, and lymphoproliferative disorders. ■ Cases of lymphoproliferative disorders and lymphoma have occurred in Lemtrada-treated patients with MS, including a MALT lymphoma, Castleman's disease, and a fatality following treatment of non–Epstein Barr virus-associated Burkitt's lymphoma. ■ Because Lemtrada is an immunomodulatory therapy, caution should be exercised in initiating it in patients with pre-existing or ongoing malignancies. ■ Serious and life-threatening stroke (including ischemic and hemorrhagic stroke) has been reported within 3 days of administration, with most cases occurring within 1 day. Cases of cervicocephalic (e.g., vertebral, carotid) arterial dissection involving multiple arteries have been reported within 3 days of Lemtrada administration. ■ Autoimmune hepatitis causing clinically significant liver injury, including acute liver failure requiring transplant, has occurred. ■ Serious infections, including appendicitis, gastroenteritis, herpes viral infections (genital herpes, herpes simplex, herpes zoster, oral herpes), human papillomavirus (HPV [including cervical dysplasia]), pneumonia, tooth infection, and tuberculosis, have occurred. Fungal infections (e.g., oral and vaginal candidiasis) and *L. monocytogenes* infections (e.g., meningitis, encephalitis, sepsis, and gastroenteritis), including fatal cases of *Listeria* meningoencephalitis, have also been reported. ■ Serious and sometimes fatal opportunistic infections (e.g., aspergillosis, coccidioidomycosis, cytomegalovirus, histoplasmosis, nocardiosis, and *Pneumocystis jiroveci* pneumonia) have occurred. ■ Serious and sometimes fatal bacterial, protozoan, and viral infections, including those due to reactivation of latent infections reported with Campath, may occur in patients treated with Lemtrada. ■ No data are available on reactivation of hepatitis B virus (HBV) or hepatitis C virus (HCV) because these patients were excluded from trials. Consider screening patients at high risk for HBV or HCV infections; may be at risk for irreversible liver damage. ■ Lemtrada may increase the risk of acute acalculous cholecystitis. ■ Progressive multifocal leukoencephalopathy has occurred in a patient with MS. ■ Hypersensitivity pneumonitis and pneumonitis with fibrosis have occurred. ■ Lymphopenia is common; total lymphocyte counts increased to reach the lower limit of normal 6 to 12 months after each course of Lemtrada. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Campath:

Obtain a baseline CBC, including differential and platelet count. Monitor weekly or more frequently if worsening anemia, neutropenia, or thrombocytopenia develops. ■ Infusion reactions, including acute cardiac insufficiency, angioedema, anaphylactoid shock, ARDS, bronchospasm, cardiac arrhythmias and/or arrest, chills, dyspnea, fever, hypotension, MI, N/V, pulmonary infiltrates, rash, respiratory arrest, rigors, syncope, and/or urticaria may occur. Reactions may be severe. Acute infusion-related reactions were most common during the first week of therapy in clinical studies. Premedicate patient and monitor carefully during infusion. Withhold Campath for Grade 3 or 4 infusion reactions. Gradual escalation to the recommended maintenance dose is required at the initiation of therapy and after interruption of therapy for 7 or more days. See Usual Dose. ■ Monitor for S/S of any infection. ■ Monitor for CMV infection during and for at least 2 months after completion of therapy. Treat confirmed infection or viremia as indicated with ganciclovir (Cytovene) or equivalent. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ CD4+ counts should be followed after therapy until recovery to equal to or greater than 200 cells/mm^3. See Usual Dose.

Lemtrada:

Obtain baseline CBC with differential, serum creatinine levels, urinalysis with urine cell counts, a test of thyroid function (e.g., thyroid-stimulating hormone [TSH] level), and serum transaminases ALT, AST, and total bilirubin levels. Measure the urine protein-to-creatine ratio before initiating therapy. ■ Repeat CBC, SCr, and urinalysis with urine cell counts at monthly intervals; repeat TSH every 3 months. Repeat serum transaminases and total bilirubin levels periodically. Continue for 48 months after the last dose. After 48 months, perform testing based on clinical findings that suggest autoimmunity (e.g., ITP, anti-GBM disease, thyroid disorders, cytopenias). Symptoms of autoimmune hemolytic anemia may include chest pain, dark urine, jaundice, tachycardia, and weakness. ■ TB screening recommended before initiating therapy with Lemtrada. Treat appropriately if screening is positive. ■ Monitor vital signs before the infusion and periodically during the infusion. ■ Monitor for S/S of an infusion reaction (e.g., anaphylaxis, angioedema, bradycardia, bronchospasm, chest pain, fever, headache, hypertension, hypotension, rash, tachycardia [including atrial fibrillation], transient neurologic symptoms) during and for a minimum of 2 hours after each infusion. Serious infusion reactions have been reported more than 24 hours after an infusion. ■ Additional monitoring may be indicated in patients predisposed to cardiovascular or pulmonary compromise. ■ Monitor for symptoms of thyroid cancer (e.g., new lump or swelling in the neck, pain in the front of the neck, persistent hoarseness or other voice changes, trouble swallowing or breathing, a constant cough not due to an upper respiratory tract infection). ■ Perform baseline and yearly skin examinations to monitor for melanoma. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3) and S/S of ITP (e.g., easy bruising, petechiae, spontaneous mucocutaneous bleeding, heavier than normal or irregular menstrual bleeding). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). Hemoptysis may also be indicative of anti-GBM disease, and an appropriate differential diagnosis must be undertaken. ■ Monitor for S/S of nephropathy or anti-GBM disease (e.g., change in color of urine, decreased urine output, dyspnea, edema, elevated SCr levels, hematuria or proteinuria, hemoptysis [from alveolar hemorrhage]) during treatment and after treatment is completed. Anti-GBM disease can be life-threatening if left untreated. Early evaluation and treatment is required to improve outcomes, including preservation of renal function. For urine dipstick results of 1+ protein or greater, measure the urine protein-to-creatinine ratio. For ratios greater than 200 mg/g, increase in SCr greater than 30%, or unexplained hematuria, perform further evaluation for nephropathies. Increased SCr with hematuria or signs of pulmonary involvement of anti-GBM disease (e.g., hemoptysis, exertional dyspnea) warrant immediate evaluation. ■ Monitor for unexplained liver enzyme elevations and symptoms suggestive of hepatic dysfunction (e.g., abdominal pain, anorexia, fatigue, jaundice and/or dark urine, unexplained nausea, and vomiting). If S/S of autoimmune hepatitis occur, promptly measure serum transaminases and total bilirubin and interrupt or discontinue treatment as appropriate. ■ Monitor for S/S of infection and consider delaying administration in patients with active infection until the infection is fully controlled. Monitor for symptoms of *Listeria* infection (fever, chills, diarrhea, nausea, vomiting, headache, pain in joints and muscles, neck stiffness, difficulty walking, mental status changes, coma, and other neurologic changes). *Listeria* infection can lead to significant complications or death. ■ Monitor for S/S of acute acalculous cholecystitis (e.g., abdominal pain, abdominal tenderness, fever, nausea, and vomiting). Leukocytosis and abnormal liver enzymes are also commonly observed. Acute acalculous cholecystitis is associated with high morbidity and mortality rates. If suspected, evaluate and treat promptly. ■ Monitor for S/S suggestive of PML (e.g., changes in thinking; disturbance of vision, memory, or orientation leading to confusion; personality changes; and progressive weakness on one side of the body or clumsiness of limbs). Typical symptoms associated with PML are diverse and progress over days to weeks. MRI findings may be apparent before clinical S/S. Withhold treatment and perform appropriate diagnostic evaluation at the first S/S of PML. ■ Annual HPV screening is recommended for female patients. ■ See Drug/Lab Interactions.

Patient Education:

Campath and Lemtrada:

Promptly report any unusual side effects or signs of bleeding or bruising, infection (e.g., fever or swollen glands), or infusion reaction (e.g., difficulty breathing, rash). ■ See Appendix D, p. 1311.

Campath:

Women of childbearing potential and men of reproductive potential should use effective contraceptive methods during treatment and for a minimum of 6 months following therapy. ■ Irradiation of blood products is required. ■ Take prophylactic anti-infectives for PCP and herpes virus as prescribed.

Lemtrada:

Review Medication Guide before each treatment course. ■ Complete any necessary immunizations at least 6 weeks before treatment with Lemtrada. ■ Inform health care provider of previous Campath use. ■ To avoid in utero exposure to Lemtrada, women of childbearing potential should use effective contraceptive measures during treatment and for 4 months following therapy. ■ Serious infusion reactions may occur after the infusion is complete. ■ Seek immediate medical attention if symptoms of stroke or cervicocephalic arterial dissection occur (e.g., neck pain, weakness on one side of the body, facial droop, difficulty with speech, sudden severe headache). ■ Seek immediate medical help for bruising, petechiae, spontaneous mucocutaneous bleeding (e.g., epistaxis, hemoptysis), or heavier than normal or irregular menstrual bleeding. ■ Promptly report abdominal pain, anorexia, bleeding, chest pain or tightness, cough, dark urine, easy bruising, fatigue, hemoptysis, jaundice, shortness of breath, tachycardia, unexplained nausea or vomiting, and wheezing. ■ May cause thyroid disorders. Promptly report symptoms (e.g., weight loss or gain, fast heartbeat or palpitations, eye swelling, constipation, or feeling cold). ■ May increase the risk of malignancies, including thyroid cancer and melanoma. ■ Baseline and yearly skin examinations recommended. ■ Carry the LEMTRADA REMS Patient Safety Information Card in case of emergency. ■ Take prescribed medication for herpes prophylaxis as directed by health care provider. ■ Yearly HPV screening is recommended. ■ May increase the risk of suicidal thoughts and behavior. Promptly report emergence or worsening of S/S of depression, any unusual changes in mood or behavior, or thoughts about self-harm. ■ Seek prompt medical help for symptoms of *Listeria* infection. ■ Avoid or adequately heat foods that are potential sources of *L.*

monocytogenes (e.g., deli meat, dairy products made with unpasteurized milk, soft cheeses, or undercooked meat, seafood, or poultry) before starting treatment. The incubation period for *L. monocytogenes* ranges from 3 to 70 days; in most cases S/S of invasive listeriosis start within 1 month of exposure to *L. monocytogenes*. ■ Report S/S of acute acalculous cholecystitis. ■ Periodic laboratory monitoring required for prolonged period of time (48 months or longer). ■ Encourage women exposed to Lemtrada during pregnancy to enroll in the pregnancy exposure registry; see Lemtrada prescribing information.

Maternal/Child:

Campath and Lemtrada: May cause fetal harm. Effective contraception required; see Patient Education.

Campath:

Discontinue breast-feeding during treatment. ■ Safety and effectiveness for use in pediatric patients not established.

Lemtrada:

Autoantibodies may be transferred from the mother to the fetus during pregnancy. Placental transfer of antithyroid antibodies resulting in neonatal Graves' disease has been reported. ■ May induce persistent thyroid disorders. Untreated hypothyroidism in pregnant women increases the risk of miscarriage and may have effects on the fetus, including mental retardation and dwarfism. ■ There are no data on the presence of alemtuzumab in human milk, the effects on the breast-fed infant, or the effects of the drug on milk production. ■ Safety and effectiveness for use in pediatric patients less than 17 years of age not established. Use is not recommended in pediatric patients due to the risks of autoimmunity, infusion reactions, and stroke and because it may increase the risk of malignancies (lymphoma, lymphoproliferative disorders, melanoma, and thyroid).

Elderly:

Campath:

Clinical studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently than younger patients. Other clinical experience has not identified differences in response.

Lemtrada:

Clinical studies did not include sufficient numbers of patients age 65 and over. Differences in response compared with younger adults not known.

DRUG/LAB INTERACTIONS

Campath and Lemtrada

Do not administer **chloroquine or live virus vaccines** to patients receiving alemtuzumab. ■ Campath and Lemtrada both contain the same active ingredient,

alemtuzumab. Before use in a patient who has received **either Campath or Lemtrada** previously, consider the potential for additive and long-lasting effects on the immune system.

Campath

No formal drug interaction studies have been performed.

Lemtrada

Concomitant use with antineoplastic or immunosuppressive therapies could increase the risk of immunosuppression.

SIDE EFFECTS

Campath

The most common serious side effects are cytopenias (anemia, lymphopenia, neutropenia, thrombocytopenia), infections (CMV viremia, CMV infection, other infections), and infusion reactions (chills, dyspnea, fever, hypotension, nausea, rash, tachycardia, urticaria). GI symptoms (abdominal pain, diarrhea, N/V) and neurologic symptoms (insomnia, anxiety) are also commonly reported. Autoimmune hemolytic anemia or autoimmune idiopathic thrombocytopenia, headache, hypertension, tremor, and many other adverse reactions have been reported less frequently.

Lemtrada

The most common serious side effects include acute acalculous cholecystitis, autoimmunity, autoimmune hepatitis, cervicocephalic arterial dissection, glomerular nephropathies, immune thrombocytopenia, infections, infusion reactions, malignancies, other autoimmune cytopenias, PML, pneumonitis, stroke, and thyroid disorders. The most common side effects reported include abdominal pain, arthralgia, back pain, diarrhea, dizziness, fatigue, fever, flushing, fungal infections, headache, herpes viral infection, insomnia, nasopharyngitis, nausea and vomiting, oropharyngeal pain, pain in extremities, paresthesia, pruritus, rash, sinusitis, thyroid gland disorders, upper respiratory tract infection, urinary tract infection, urticaria. Lymphopenia and suicidal behavior have also been reported. All side effects listed under Campath may occur.

Post-Marketing:

Campath:

Acute acalculous cholecystitis, aplastic anemia, cardiotoxicity (e.g., cardiomyopathy, CHF, and decreased ejection fraction [some patients had been previously treated with cardiotoxic agents]), cerebrovascular disorders (cervicocephalic arterial dissection, stroke [including hemorrhagic and ischemic]), chronic inflammatory demyelinating polyradiculoneuropathy, EBV-associated lymphoproliferative disorder, fatal infusion reactions, fatal transfusion-associated graft-versus-host disease, Goodpasture’s syndrome, Grave’s disease, Guillain-Barré syndrome, optic neuropathy, reactivation of latent viruses, serum sickness, tumor lysis syndrome.

Lemtrada:

Acalculous cholecystitis, autoimmune hepatitis, hemophagocytic lymphohistiocytosis, neutropenia, opportunistic infections, PML, pulmonary alveolar hemorrhage, thrombocytopenia, vasculitis. Post-marketing symptoms under Campath may occur.

ANTIDOTE

Campath and Lemtrada

Notify physician of all side effects. Treatment of most reactions will be supportive. Therapy should be temporarily discontinued during serious infection, serious hematologic toxicity (except lymphopenia), or other serious toxicity until the infection or adverse event resolves. Discontinue medication for severe reactions. Infusion reactions may be treated with acetaminophen, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone), epinephrine, and meperidine as indicated. Treat hypersensitivity reactions with epinephrine, antihistamines, and corticosteroids as needed. Resuscitate as indicated.

Campath

Discontinue medication permanently for severe reactions, including autoimmune anemia or thrombocytopenia. Administration of irradiated blood products and/or blood modifiers (e.g., darbepoetin [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Median durations of neutropenia were 28 to 37 days, and median durations of thrombocytopenia were 9 to 21 days. Median time to recovery of CD4+ counts to equal to or greater than 200/mm^3 is 2 to 6 months; however, full recovery of CD4+ and CD8+ counts may take more than 12 months. Discontinue alemtuzumab and provide supportive therapy in overdose.

Lemtrada

Consider pretreatment with antihistamines and/or antipyretics. Epinephrine and atropine were administered to a number of patients who experienced an infusion reaction in clinical trials. If ITP is suspected, obtain a CBC. If ITP is confirmed, treat appropriately. If anti-GBM disease is suspected, urgent evaluation and treatment are required. Anti-GBM disease can lead to renal failure requiring dialysis or transplantation and can be life threatening if left untreated. There is no known antidote for overdose.

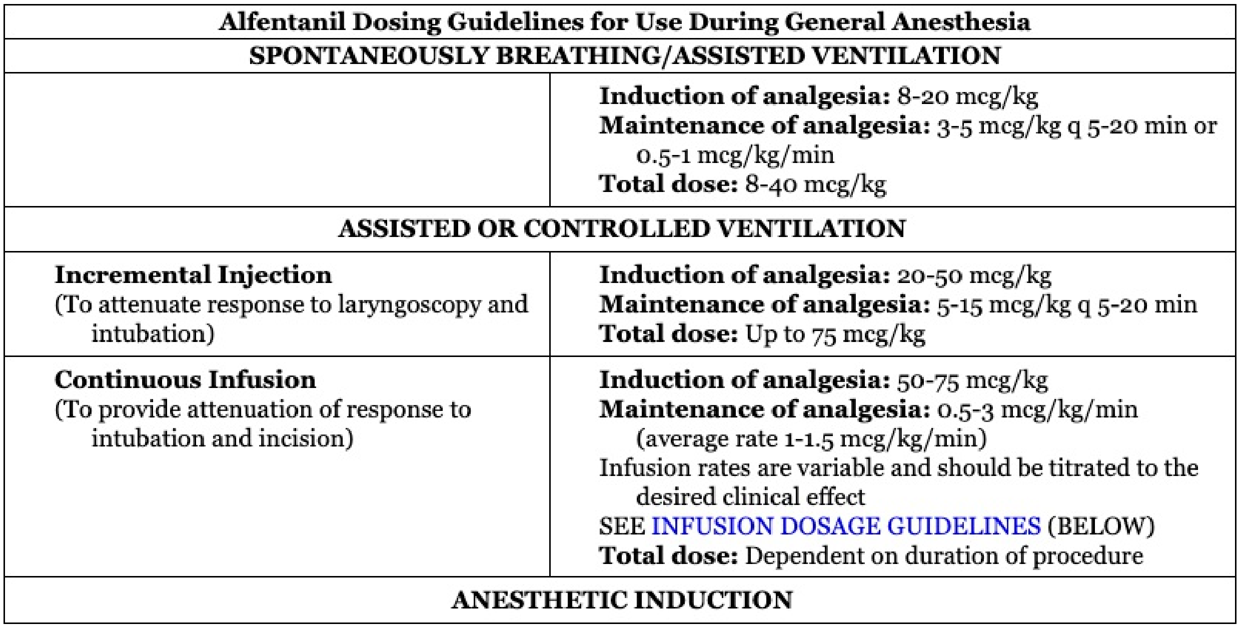
ALFENTANIL HYDROCHLORIDE BBW

(al-**FEN**-tah-nil hy-droh-**KLOR**-eyed)
General anesthetic
Opioid analgesic agonist
Anesthesia adjunct
pH 4 to 6

USUAL DOSE

Adults and pediatric patients 12 years of age and older:

Dose must be individualized and titrated to the desired effect in each patient according to body weight, physical status, underlying pathologic condition, use of other drugs, and type and duration of surgical procedure and anesthesia. The selection of preanesthetic medications should be based on the needs of the patient. The neuromuscular blocking agent selected should be **compatible** with the patient's condition, taking into account the hemodynamic effects of a particular muscle relaxant and the degree of skeletal muscle relaxation required. Because administration of the induction dose may produce a loss of vascular tone and hypotension, consider administering IV fluids before induction; see Drug/Lab Interactions and Dose Adjustments.



Alfentanil Dosing Guidelines for Use During General Anesthesia	
SPONTANEOUSLY BREATHING/ASSISTED VENTILATION	
	Induction of analgesia: 8-20 mcg/kg **Maintenance of analgesia:** 3-5 mcg/kg q 5-20 min or 0.5-1 mcg/kg/min **Total dose:** 8-40 mcg/kg
ASSISTED OR CONTROLLED VENTILATION	
Incremental Injection (To attenuate response to laryngoscopy and intubation)	**Induction of analgesia:** 20-50 mcg/kg **Maintenance of analgesia:** 5-15 mcg/kg q 5-20 min **Total dose:** Up to 75 mcg/kg
Continuous Infusion (To provide attenuation of response to intubation and incision)	**Induction of analgesia:** 50-75 mcg/kg **Maintenance of analgesia:** 0.5-3 mcg/kg/min (average rate 1-1.5 mcg/kg/min) Infusion rates are variable and should be titrated to the desired clinical effect SEE INFUSION DOSAGE GUIDELINES (BELOW) **Total dose:** Dependent on duration of procedure
ANESTHETIC INDUCTION	

	Induction of anesthesia: 130-245 mcg/kg; administer slowly (over 3 minutes) **Maintenance of anesthesia:** 0.5-1.5 mcg/kg/min of general anesthetic Infusion rates are variable and should be titrated to the desired clinical effect SEE INFUSION DOSAGE GUIDELINES (BELOW) **Total dose:** Dependent on duration of procedure At these doses, truncal rigidity should be expected and a muscle relaxant should be used In patients receiving anesthetic (induction) doses of alfentanil, it is essential that qualified personnel and adequate facilities are available for the management of intraoperative and postoperative respiratory depression
MONITORED ANESTHESIA CARE (MAC)	
For sedated and responsive, spontaneously breathing patients	**Induction of MAC:** 3-8 mcg/kg **Maintenance of MAC:** 3-5 mcg/kg q 5-20 min or 0.25-1 mcg/kg/min Infusion rates are variable and should be titrated to the desired clinical effect SEE INFUSION DOSAGE GUIDELINES (BELOW) **Total dose:** 3-40 mcg/kg Patients receiving MAC should be continuously monitored by persons not involved in the conduct of the surgical or diagnostic procedure.
INFUSION DOSAGE GUIDELINES FOR CONTINUOUS INFUSION	
Continuous infusion: 0.5-3 mcg/kg/min administered with nitrous oxide/oxygen in patients undergoing general surgery. Following an anesthetic induction dose of alfentanil, the infusion rate requirements for alfentanil are reduced by 30%-50% for the first hour of maintenance. Requirements for volatile inhalation anesthetics are also reduced by 30% to 50% for the first hour of maintenance. Changes in vital signs that indicate a response to surgical stress or lightening of anesthesia may be controlled by increasing the alfentanil to a maximum of 4 mcg/kg/min and/or administration of bolus doses of 7 mcg/kg. If changes are not controlled after three bolus doses given over a 5-minute period, a barbiturate, vasodilator, and/or inhalation agent should be used. Infusion rates should always be adjusted downward in the absence of these signs until there is some response to surgical stimulation. Rather than an increase in infusion rate, 7 mcg/kg bolus doses of alfentanil or a potent inhalation agent should be administered in response to signs of lightening of anesthesia within the last 15 minutes of surgery. Alfentanil infusion should be discontinued at least 10 to 15 minutes before the end of surgery. Continue infusion to end of procedure during MAC, then discontinue. In patients administered anesthetic (induction) doses of alfentanil, it is essential that qualified personnel and adequate facilities are available for the management of intraoperative and postoperative respiratory depression.	

DOSE ADJUSTMENTS

Reduce dose of one or both agents when given in combination with other CNS depressants (e.g., barbiturates, inhalation anesthetics, narcotic analgesics, tranquilizers). ■ Calculate dose based on lean body weight in obese patients (more than 20% above ideal body weight). ■ Reduced initial dose required in elderly or debilitated patients (a 40% reduction was required in one study); reduced supplemental doses, a slower infusion rate, or longer intervals between doses may be required based on effects of initial dose. ■ Doses appropriate for general population may cause serious respiratory depression in vulnerable patients. ■ Reduced dose may be required in impaired renal and hepatic function. ▪ See Drug/Lab Interactions.

DILUTION

IV injection:

Small volumes may be given undiluted (usually by the anesthesiologist). Use of tuberculin syringe recommended (1 mL equals 500 mcg). Further dilution with 5 mL of NS to facilitate titration is appropriate.

Infusion:

Desired concentration range is 25 to 80 mcg/mL. The manufacturer provides the following example of an infusion solution: Dilute 20 mL alfentanil with 230 mL NS, D5NS, D5W, or LR to achieve a concentration of 40 mcg/mL.

Storage:

Store ampules at CRT; protect from light.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Administer over a minimum of 3 minutes. Rapid administration of lower doses or administration of full anesthetic doses will result in muscle rigidity, apnea, respiratory paralysis, loss of vascular tone, and hypotension. Titrate rate to desired patient response.

Infusion:

See Usual Dose.

ACTIONS

An opioid agonist. The principal actions of therapeutic value are analgesia and sedation. Binds to receptors in the CNS, increasing the pain threshold and altering the perception of pain. Produces respiratory depression by direct action on brain stem respiratory centers. Produces peripheral vasodilation, which may result in orthostatic hypotension or syncope. Onset of action is immediate. Duration of action is dose dependent and is 30 to 60 minutes. Has a terminal half-life of 90 to 111 minutes. Metabolized in the liver. Excreted as metabolites in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Analgesic adjunct given in incremental doses in the maintenance of anesthesia with barbiturate/nitrous oxide/oxygen. ▪ Analgesic administered by continuous infusion with nitrous oxide/oxygen in the maintenance of general anesthesia. ■ Primary anesthetic agent for the induction of anesthesia in patients undergoing general surgery requiring endotracheal intubation and mechanical ventilation. ■ Analgesic component for monitored anesthesia care (MAC) during surgical or diagnostic procedures.

CONTRAINDICATIONS

Known hypersensitivity to alfentanil.

PRECAUTIONS

For IV use only. ■ Alfentanil exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing alfentanil, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ Should be administered by persons specifically trained in the use of IV anesthetics and management of the respiratory effects of potent opioids. ■ Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. An opioid antagonist (e.g., naloxone), emergency drugs, resuscitative and intubation equipment, and oxygen must be readily available. ■ Staff must be skilled in medical management of critically ill patients, cardiovascular resuscitation, and airway management. ■ Use caution; plasma clearance may be reduced and recovery time prolonged in elderly, cachectic, or debilitated patients and in patients with impaired liver function (half-life prolonged [up to 5.8 hours]); reduced dose may be indicated. ■ Use caution in patients with pulmonary disease, decreased respiratory reserve, or potentially compromised respiration. May cause rigidity of chest and abdominal muscles, decrease respiratory drive, and increase airway resistance; may require assisted or controlled ventilation. ■ The incidence and severity of muscle rigidity is usually dose related. Administration of anesthetic induction dosages (above 130 mcg/kg) will consistently produce muscular rigidity with an immediate onset. The incidence of muscle rigidity may be reduced by (1) routine methods of administration of neuromuscular blocking agents for balanced opioid anesthesia, (2) administration of up to one-fourth the full paralyzing dose of a neuromuscular blocking agent just before administration of alfentanil at dosages up to 130 mcg/kg (following loss of consciousness, a full paralyzing dose should be administered), or (3) simultaneous administration of alfentanil and a full paralyzing dose of a neuromuscular blocking agent when alfentanil is used in rapidly administered anesthetic dosages (above 130 mcg/kg). ■ Cases of serotonin syndrome have been reported during concomitant use of alfentanil with serotonergic drugs. Symptoms may include mental status changes (e.g., agitation, coma, hallucinations), autonomic instability (e.g., hyperthermia, labile blood pressure, tachycardia), neuromuscular aberrations (e.g., incoordination, hyperreflexia, rigidity), and/or GI symptoms (e.g., diarrhea, nausea, vomiting). ■ Use caution in patients with head injury or increased intracranial pressure. Respiratory depression may cause an increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Use caution in patients with bradyarrhythmias. ■ Use caution in patients with biliary tract disease, including acute pancreatitis. May cause spasm of the sphincter of Oddi. Opioids may cause increases in amylase. ■ Alfentanil may increase the frequency of seizures in patients with seizure disorders. ■ Anaphylaxis has been reported. ■ See Drug/Lab Interactions.

Monitor:

Monitor vital signs continuously, including after the termination of surgery. Delayed respiratory depression, respiratory arrest, bradycardia, asystole, arrhythmias, and hypotension have been reported. ■ Can cause rigidity of respiratory muscles; concurrent use of a neuromuscular blocking agent can prevent or reverse muscle rigidity to permit controlled ventilation. ■ Adequate preoperative hydration is recommended to reduce incidence of hypotension. ■ Patients receiving MAC should be continuously monitored by persons not involved in the conduct of the surgical or diagnostic procedure. Monitor vital signs and oxygen saturation continuously. Observe for hypotension, apnea, upper airway obstruction, and/or oxygen desaturation. Oxygen supplementation should be readily available and provided where clinically indicated. ■ Keep patient supine; orthostatic hypotension and fainting may occur. ■ The respiratory depressant effect of alfentanil may persist longer than the analgesic effect. The total dose of all opioid agonists administered should be considered before ordering opioid analgesics during recovery from anesthesia. ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Monitor for S/S of a hypersensitivity reaction. ■ Monitor for S/S of serotonin syndrome if serotonergic drugs have been used concomitantly. Onset of symptoms may occur within hours to days of concomitant use. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Blurred vision, dizziness, drowsiness, or light-headedness may occur; request assistance with ambulation. ■ Review all medications for interactions. ■ Promptly report S/S of serotonin syndrome.

Maternal/Child:

Safety for use in pregnancy not established. ■ Not recommended for use during labor and delivery. ■ Consider risk versus benefit. Infants exposed to alfentanil through breast milk should be monitored for excess sedation and respiratory depression.

Elderly:

See Dose Adjustments and Precautions. ■ Decreased protein binding, decreased clearance, and possible increased brain sensitivity may make the elderly more sensitive to effects (e.g., respiratory depression, extended recovery time, urinary retention, constipation). ■ Lower doses may provide effective analgesia. ■ Consider age-related organ impairment; elimination half-life is extended, and postoperative recovery may be delayed.

DRUG/LAB INTERACTIONS

After an anesthetic induction dose of alfentanil, requirements for **volatile inhalation anesthetics** (e.g., nitrous oxide) **and/or alfentanil infusion** are reduced by 30% to

50% for the first hour of maintenance. ■ **Beta-adrenergic blocking agents** (e.g., metoprolol, timolol) may be used preoperatively to decrease hypertensive episodes during surgical procedures, but chronic use (including ophthalmic preparations) may also increase the risk of initial bradycardia. ■ Respiratory depression, CNS depression, hypotensive effects, and duration of action increased with concomitant administration of **benzodiazepines** (e.g., diazepam, midazolam) and other **CNS depressants** (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol). Reduced doses of one or both agents are usually required.When such combinations are administered, IV fluids and other measures to manage hypotension should be available. ■ Use caution with concomitant use of alfentanil and **CYP3A4 inhibitors** (e.g., macrolide antibiotics [e.g., erythromycin], azole antifungals [e.g., ketoconazole], and protease inhibitors [e.g., ritonavir]) or when discontinuing a **CYP3A4 inducer** (e.g., rifampin, carbamazepine, phenytoin) in an alfentanil-treated patient. May increase plasma concentration of alfentanil and increase or prolong opioid effects. Dose reduction may be indicated. ■ Alternatively, concomitant use of alfentanil with **CYP3A4 inducers** or discontinuation of a **CYP3A4 inhibitor** could result in lower than expected alfentanil plasma concentration and decreased efficacy. An increase in the dose of alfentanil may be required. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including alfentanil, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT$_3$ receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Respiratory depressant effects are additive with **neuromuscular blocking agents** (e.g., rocuronium, succinylcholine). ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., selegiline) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). If alfentanil is administered to a patient who has received an MAO inhibitor within the past 14 days, monitor the patient for hypertension and ensure that beta-blockers and vasodilators are available if needed. ■ **Opioid agonist/antagonist analgesics** (e.g., butorphanol, nalbuphine) may reduce the analgesic effect of alfentanil and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Alfentanil may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine, orphenadrine), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ **Cimetidine** reduces the clearance of alfentanil, extending the duration of action. Dose reduction may be indicated. ■ Cardiovascular depression has been reported when **nitrous oxide** is given with higher doses of alfentanil. Monitor patients for signs of cardiovascular depression.

SIDE EFFECTS

The most common adverse reactions are apnea, bradycardia, and rigidity. The incidence of certain side effects is influenced by the indication for use (e.g., chest wall rigidity with induction of anesthesia) and the type of surgery (e.g., higher incidence of nausea and vomiting with gynecologic surgery). Other reported side effects include agitation, anaphylaxis, arrhythmias (e.g., bradycardia, tachycardia), blurred vision, bradypnea, bronchospasm, chest wall rigidity, dizziness, headache, hypercapnia (increased CO_2), hypertension, hypotension, hypoxia, itching, laryngospasm, muscle rigidity (skeletal muscles including abdomen, chest, pharynx, neck, and extremities), myoclonic movements, nausea, postoperative confusion, postoperative euphoria, postoperative respiratory depression and sedation, shivering, skeletal muscle movements, sleepiness, somnolence, urticaria, vomiting.

Overdose:

Atypical snoring; bradycardia; circulatory depression; cold, clammy skin; death; hypotension; partial or complete airway obstruction; pinpoint pupils of eyes; pulmonary edema; respiratory depression; skeletal muscle flaccidity; somnolence progressing to stupor or coma.

Post-Marketing:

Adrenal insufficiency, anaphylaxis, androgen deficiency, serotonin syndrome.

ANTIDOTE

Many side effects are medical emergencies. Manage respiratory depression during surgery via endotracheal intubation and assisted or controlled ventilation; prolonged mechanical ventilation may be required. Treat clinically significant postoperative respiratory or circulatory depression with naloxone; titrate dose carefully to improve respirations without reversing analgesic effects. Because the duration of opioid reversal is expected to be less than the duration of action of alfentanil, careful monitoring is necessary, and repeat doses of naloxone may be required. Treat bradycardia with atropine. Treat hypotension by placing the patient in a Trendelenburg position, if possible; administer IV fluids and a vasopressor (e.g., norepinephrine, dopamine) if indicated. Muscle rigidity during anesthesia induction or surgery must be controlled with neuromuscular blocking agents and controlled ventilation with oxygen. Use a neuromuscular blocking agent prophylactically to prevent muscle rigidity or to induce muscle relaxation after rigidity occurs. Resuscitate as necessary.

ALGLUCERASE

(al-**GLU**-seh-raze)
Ceredase
Enzyme replenisher
(glucocerebrosidase)
pH 5.5 to 6

See Usual Dose. Almost all patients are now on Imiglucerase.

USUAL DOSE

Individuals now taking alglucerase will be transferred to imiglucerase (Cerezyme) as production levels of imiglucerase increase. This phase-in process began in 1997 and, according to the manufacturer, this process is complete. The majority of the few patients remaining on alglucerase are those who demonstrated sensitivity to imiglucerase. Once patients are transferred to imiglucerase, they should remain on imiglucerase.

Adults and pediatric patients over 2 years of age:

Dose is individualized to each patient based on the severity of illness and patient response. Initial doses may range from 2.5 units/kg/infusion 3 times a week to 60 units/kg/infusion once a week. Recent studies indicate that lower range initial doses may be effective. Based on disease severity, patient response, or patient convenience, the frequency can be adjusted to as often as every other day or as infrequently as every 4 weeks.

Alglucerase should be given at least every 4 weeks or symptoms and condition may relapse to pretreatment status. Patients beginning alglucerase therapy are usually given higher range initial doses for a limited time to stabilize their disease. Patients with very severe Gaucher’s disease also may require higher range initial doses and/or increased frequency because they have accumulated more lipid throughout their bodies, requiring more enzyme to remove the excess stored lipid and bring their disease under control.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

To utilize each bottle fully and reduce wasting, a single dose may be increased or decreased slightly as long as the total monthly dose remains unaltered. ■ After patient response is well established (disease symptoms lessen and the accumulated lipid is reduced), the dose may be adjusted downward to achieve the optimum individualized maintenance dose. Usually progressively lowered at 3-to 6-month intervals while response parameters are closely monitored. Optimum goal is to establish the lowest dose that is effective in maintaining control of the disease and preventing recurrence of symptoms for each patient. Evidence suggests that this therapy works with doses as low as 1 unit/kg.

DILUTION

A single dose must be diluted with NS to a total volume not to exceed 200 mL. Do not shake; may render the glycoprotein biologically inactive. Available as a single-use package containing 400 Units/5 mL (80 Units/mL).

Filters:

Use of an in-line particulate filter is recommended.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). Do not use if discolored, particulate matter present, or after expiration date on bottle. Contains no preservative; do not store opened vials for future use. Diluted in 100 to 200 mL NS, solution is stable for up to 18 hours at 2° to 8° C (36° to 46° F).

COMPATIBILITY

Manufacturer states, "Do not use as an additive with any other drug. Do not mix in any solution other than NS."

RATE OF ADMINISTRATION

A single dose equally distributed over 1 to 2 hours. Use an in-line microfilter. Use of a microdrip (60 gtt/mL) or an infusion pump is helpful. Reduction in the rate of infusion may be helpful in the event of side effects or a hypersensitivity reaction; see Antidote.

ACTIONS

A modified form of the enzyme beta-glucocerebrosidase made from human placental tissue from selected donors and purified by specific processes. Gaucher's disease is characterized by a functional deficiency in beta-glucocerebrosidase enzymatic activity and the resultant accumulation of lipid glucocerebroside in tissue macrophages (Gaucher's cells). These cells are found in the liver, spleen, bone marrow, and occasionally the lung, kidney, and intestine. Alglucerase acts like glucocerebrosidase to facilitate the hydrolysis of glucocerebroside to glucose and ceramide. Effective in controlling and actually reversing disease symptoms.

Increase in appetite and energy level and improvement in hemoglobin are often the first observable effects and may occur in 2 to 4 months. Cachexia and wasting in pediatric patients are reduced. Within 6 months splenomegaly and hepatomegaly are significantly reduced, and hemoglobin, hematocrit, erythrocyte, and platelet counts improved. Replenishment of bone marrow and improving mineralization of bone may take several years.

INDICATIONS AND USES

Long-term enzyme replacement therapy for children, adolescents, and adults with confirmed diagnosis of Type I Gaucher's disease, with S/S severe enough to result in one or more of the following conditions: moderate to severe anemia, thrombocytopenia with bleeding tendency, bone disease, significant hepatomegaly or splenomegaly, or growth retardation in children and adolescents related to Gaucher's disease.

CONTRAINDICATIONS

None known. Discontinue if there is significant clinical evidence of hypersensitivity to alglucerase.

PRECAUTIONS

Effective only via IV route. ■ Should be used under the direction of a physician knowledgeable in the management of Gaucher's disease. ■ Some patients have developed IgG Antibody to alglucerase. Antibody development usually occurs within 6 to

12 months of initiating treatment. Patients with antibodies are at increased risk of hypersensitivity reactions. Pretreatment with antihistamines (e.g., diphenhydramine) may lessen the severity of these reactions. ■ Human chorionic gonadotropin (hCG) has been detected in this product. Use caution in patients with androgen-sensitive malignancies (e.g., prostate cancer) and in patients with known allergies to hCG. May cause early virilization (early development of secondary sex characteristics) in pediatric males. ■ Special processing minimizes risk of HIV and hepatitis. Inactivation of all viruses cannot be guaranteed. Assess benefits and risks of treatment before use. ■ No obvious toxicity was detected after single doses up to 234 Units/kg; no experience with higher doses.

Monitor:

Evaluation of hemoglobin, hematocrit, platelets, WBC count, acid phosphatase (AP), plasma glucocerebroside, liver and/or spleen size, and bone changes is required before and during therapy. Frequency determined by patient response; more frequent when determining response to initial dose and when dose is being adjusted (i.e., every 3 to 6 months). Blood tests will be done more frequently, since anemia is the first symptom to improve. ■ MRI provides the best evaluation of liver and spleen. ■ Standard x-rays provide adequate evaluation of bone changes. ■ If symptoms suggestive of a hypersensitivity reaction occur, treat the reaction as appropriate, then draw a serum sample for tryptase levels and complement activation within 2 hours of the reaction. Subsequent testing for antibodies to alglucerase is suggested. Monitor for signs of early development of secondary sex characteristics in males under 10 years of age. ■ Determine patency of vein; discomfort, burning, and swelling may occur at the site. ■ Observe patient closely for signs of improvement (e.g., increased energy, reduced bleeding tendency, reduction in size of liver and/or spleen, reduced joint swelling, reduced bone pain).

Patient Education:

Treatment required for life. No longer than 1 month should elapse between treatments, or symptoms and condition may relapse to the pretreatment state.

Maternal/Child:

Category C: use in pregnancy only if clearly needed. No studies available on fetal harm or reproductive capacity. ■ Safety for use during breast-feeding not established. Not known if alglucerase is secreted in breast milk. ■ Has been used in pediatric patients under 2 years of age, but safety and effectiveness not established. Data are limited.

DRUG/LAB INTERACTIONS

None indicated; limited information available. ■ **False-positive pregnancy tests** have been reported.

SIDE EFFECTS

Burning, discomfort, swelling, and sterile abscess at the injection site are most common. Other reported side effects include alteration of sense of smell, backache, chills, diarrhea, fatigue, fever, headache, hot flashes, light-headedness, menstrual abnormalities, nausea, oral ulcerations, transient peripheral edema, and vomiting.

A protein immune reaction may develop. Hypersensitivity reactions have occurred during or shortly after an infusion. S/S may include abdominal cramping, angioedema, chest discomfort, flushing, hypotension, pruritus, respiratory symptoms, and urticaria.

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. Discontinue alglucerase for severe clinical evidence of hypersensitivity. Pretreatment with antihistamines (e.g., diphenhydramine) and a reduced rate of infusion may allow continuation of alglucerase. Treat anaphylaxis and resuscitate as necessary.

ALGLUCOSIDASE ALFA BBW

(al-**GLU**-koh-sih-daze **AL**-fah)
Myozyme, Lumizyme
Enzyme replenisher

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

Consider pretreatment with antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen), and/or corticosteroids (e.g., dexamethasone); see Precautions and Monitor. Infusion reactions may occur at any time during or up to 2 hours after the infusion and are more likely with higher infusion rates.

Alglucosidase alfa:

20 mg/kg of body weight as an infusion every 2 weeks.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

None indicated.

DILUTION

Each vial contains 50 mg of alglucosidase alfa. Determine the number of vials needed to provide the calculated dose as follows:

$$\text{Patient dose (mg)} = \text{Patient weight (kg)} \times 20 \text{ mg/kg}$$

$$\text{\# of vials needed} = \text{Patient dose (mg)} \div 50 \text{ mg/vial}$$

For example, a 16-kg patient would receive a 320-mg dose (16 kg × 20 mg/kg = 320 mg). 320 mg divided by 50 mg/vial equals 6.4 vials. Round up to the next whole number, so 7 vials would be required. Handle vials carefully; ***avoid shaking or agitation.*** Before reconstitution, allow vials and diluent to reach room temperature (should take approximately 30 minutes). Reconstitute each vial with 10.3 mL SW. ***Do not use a filter needle during any step of the alglucosidase alfa dilution process; see Filters.*** Direct diluent by slowly releasing each drop down the inside wall of each vial. Avoid forceful impact of the SW on the lyophilized cake, and avoid foaming. Roll and tilt each vial gently to dissolve; ***do not shake.*** Protect reconstituted solution from light. Total extractable volume in each vial is 50 mg in 10 mL (5 mg/mL). A few thin white strands or translucent fibers are expected and will be removed by the in-line filter during administration. Must be further diluted in a specific amount of NS ***immediately*** after reconstitution to a final concentration of 0.5 to 4 mg/mL. See chart under Rate of Administration for the specific volume of diluent to use based on weight in kg. Total infusion volume for a 16-kg patient equals 100 mL (64 mL of alglucosidase alfa and 36 mL NS). Remove excess volume from the infusion bag to achieve the desired volume (36 mL of NS for the preceding example). To minimize particle formation due to the sensitivity of alglucosidase alfa to air-liquid interfaces, remove air space from the infusion bag containing the desired volume for dilution. Next, slowly withdraw the calculated dose of drug from the reconstituted vials (a total of 64 mL in the preceding example) and add it to the NS remaining in the infusion bag (36 mL in the preceding example). ***Alglucosidase alfa must be added into the fluid itself and not into the air space of the infusion bag.*** Use only clear solutions. Gently invert or massage the infusion bag to mix the solution. Avoid foaming. Do not shake.

Filters:

Do not use filter needles during reconstitution or dilution. For administration, filter diluted solution through an in-line, low–protein-binding, 0.2-micron filter.

Storage:

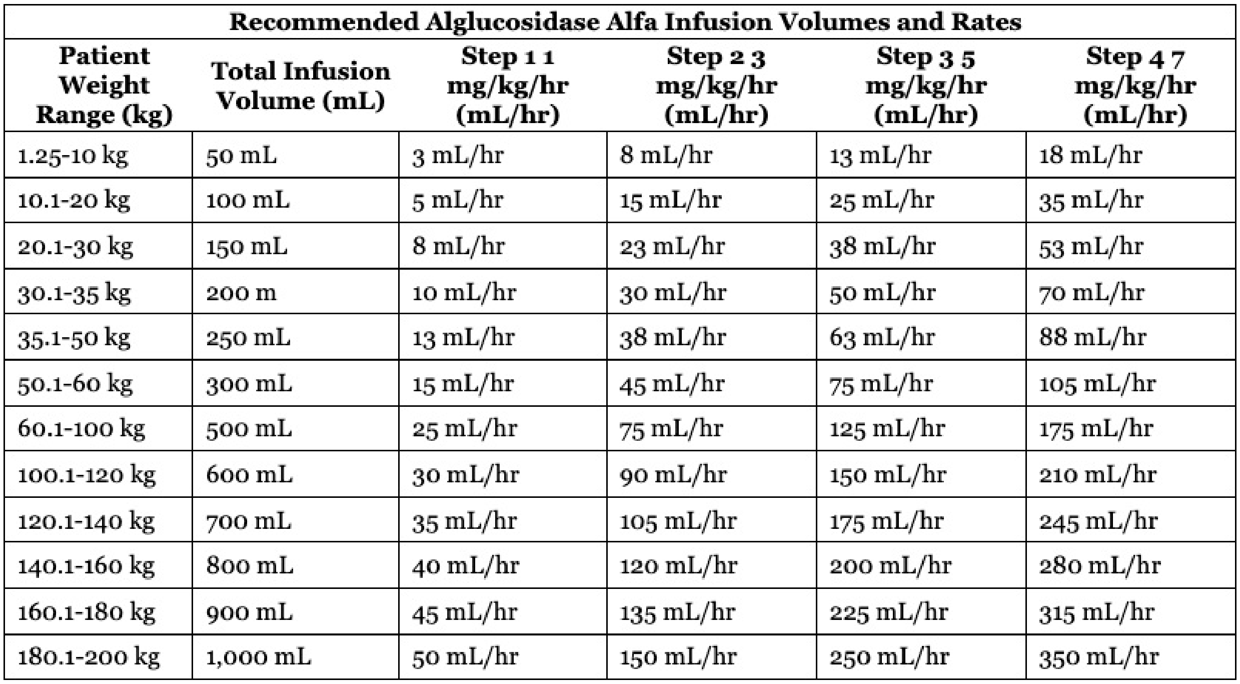
Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Do not use after the expiration date on the vial. Immediate use of reconstituted and diluted solutions is preferred but, if necessary, they may be refrigerated for up to 24 hours. Discard unused reconstituted solution. Protect from light and do not freeze.

COMPATIBILITY

Manufacturer states, "Should not be infused in the same IV line with other products."

RATE OF ADMINISTRATION

Infusion reactions may occur even when the patient has been premedicated and are more likely with higher infusion rates. Use of an infusion pump is required. For administration, diluted solution should be filtered through an in-line, low–protein-binding, 0.2-micron filter. Begin with an **initial infusion rate** of no more than 1 mg/kg/hr. After patient tolerance is established, the infusion may be increased by 2 mg/kg/hr every 30 minutes until a **maximum infusion rate** of 7 mg/kg/hr is reached. Obtain vital signs at the end of each step. Should an infusion reaction occur at any step, slow or temporarily discontinue infusion until symptoms subside. Additional premedication may be indicated; see Antidote. If the patient remains stable, continue at 7 mg/kg/hr until the infusion is complete (approximately 4 hours). Total volume of infusion is determined by patient's body weight. Volume and rate of infusion for given weight ranges are listed in the following chart.



Recommended Alglucosidase Alfa Infusion Volumes and Rates

Patient Weight Range (kg)	Total Infusion Volume (mL)	Step 1 1 mg/kg/hr (mL/hr)	Step 2 3 mg/kg/hr (mL/hr)	Step 3 5 mg/kg/hr (mL/hr)	Step 4 7 mg/kg/hr (mL/hr)
1.25-10 kg	50 mL	3 mL/hr	8 mL/hr	13 mL/hr	18 mL/hr
10.1-20 kg	100 mL	5 mL/hr	15 mL/hr	25 mL/hr	35 mL/hr
20.1-30 kg	150 mL	8 mL/hr	23 mL/hr	38 mL/hr	53 mL/hr
30.1-35 kg	200 m	10 mL/hr	30 mL/hr	50 mL/hr	70 mL/hr
35.1-50 kg	250 mL	13 mL/hr	38 mL/hr	63 mL/hr	88 mL/hr
50.1-60 kg	300 mL	15 mL/hr	45 mL/hr	75 mL/hr	105 mL/hr
60.1-100 kg	500 mL	25 mL/hr	75 mL/hr	125 mL/hr	175 mL/hr
100.1-120 kg	600 mL	30 mL/hr	90 mL/hr	150 mL/hr	210 mL/hr
120.1-140 kg	700 mL	35 mL/hr	105 mL/hr	175 mL/hr	245 mL/hr
140.1-160 kg	800 mL	40 mL/hr	120 mL/hr	200 mL/hr	280 mL/hr
160.1-180 kg	900 mL	45 mL/hr	135 mL/hr	225 mL/hr	315 mL/hr
180.1-200 kg	1,000 mL	50 mL/hr	150 mL/hr	250 mL/hr	350 mL/hr

ACTIONS

A recombinant form of the human enzyme acid alpha-glucosidase (GAA). Pompe disease is an inherited disease caused by the deficiency or lack of the enzyme acid alpha-glucosidase. Also known as glycogen storage disease type II. The deficiency of GAA results in the accumulation of glycogen in various tissues, particularly cardiac and skeletal muscles and hepatic tissues. This leads to the development of cardiomyopathy, progressive muscle weakness, and impairment of respiratory function. GAA binds to specific receptors on the cell surface and is internalized and transported into lysosomes. Through a specific process, it results in increased enzymatic activity and decreases the accumulation of glycogen. Half-life is 2.3 hours.

INDICATIONS AND USES

For use in patients with Pompe disease (GAA deficiency). It has been shown to improve ventilator-free survival in patients with infantile-onset Pompe disease as compared with an untreated historical control. ■ Use in patients with other forms of Pompe disease has not been adequately studied to ensure safety and efficacy. Another formulation of alglucosidase alfa (Lumizyme) is indicated for patients of all ages with Pompe disease

(GAA deficiency).

CONTRAINDICATIONS

Manufacturer states, “None known”; see Precautions.

PRECAUTIONS

Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Life-threatening anaphylactic and severe allergic reactions have been observed during and up to 3 hours after completion of infusion. Infusion and/or hypersensitivity reactions may be life threatening and have included anaphylactic shock, angioedema, bradycardia, bronchospasm, cardiac arrest, dyspnea, hypotension, hypoxia, respiratory distress, throat tightness, and urticaria. ■ Other reactions include back pain, cold sweat, cyanosis, flushing/erythema, hyperhidrosis, hypertension, livedo reticularis, nodal rhythm, pallor, periorbital edema, peripheral coldness, pruritus, rales, rash, tachycardia, tachypnea, ventricular extrasystoles, and wheezing. Some reactions were IgE mediated. ■ Severe cutaneous reactions, including necrotizing skin lesions, have been reported. Systemic immune-mediated reactions, including severe inflammatory arthropathy and nephrotic syndrome secondary to membranous glomerulonephritis, have been observed. May occur several weeks to 3 years after initiation of therapy. ■ Use caution when administering a general anesthetic to patients with Pompe disease. Severe cardiac and skeletal (including respiratory) muscle weakness can complicate the administration of the anesthetic. Ventricular arrhythmias and bradycardia resulting in cardiac arrest or death or requiring cardiac resuscitation have been observed in patients with cardiac hypertrophy during general anesthesia for central venous catheter placement. ■ During infusions, patients with acute underlying respiratory illness or compromised cardiac and/or respiratory function may be at risk for serious exacerbation of their cardiac or respiratory compromise. Acute cardiorespiratory failure requiring intubation and inotropic support has been observed. ■ Infusion reactions occurred in over 50% of patients in clinical studies. They may occur at any time during or up to 2 hours after the infusion, are more likely with higher infusion rates, and may range from mild to severe. Severe infusion reactions included cyanosis, decreased oxygen saturation, fever, hypotension, and tachycardia; see Side Effects. ■ Use extreme care if a decision is made to re-administer after a severe hypersensitivity or infusion reaction. Some patients have been rechallenged and have been able to continue therapy under close clinical supervision. ■ Potential for immunogenicity exists. The majority of patients developed antibodies to alglucosidase alfa, and most developed within 3 months. Patients who develop sustained titers equal to or greater than 12,800 may have a poorer clinical response to treatment, may lose motor function as antibody titers increase, may have an increased risk of infusion reaction, or may have an increased clearance of the drug; see Monitor.

Monitor:

Evaluate liver enzymes before initiating therapy and periodically thereafter. Obtain baseline vital signs and repeat as needed and with each increase in dosage. ■ Observe patient continuously for symptoms of infusion-related or hypersensitivity reactions. If anaphylaxis or severe allergic reaction occurs, discontinue immediately and initiate appropriate medical treatment. Severe reactions may require infusion interruption, administration of antihistamines, corticosteroids, IV fluids, epinephrine, and/or oxygen. ■ Patients with acute underlying respiratory illness or compromised cardiac and/or respiratory function may require prolonged observation times. ■ Monitor for development of systemic immune complex–mediated reactions involving the skin and other organs. Periodic urinalysis should be obtained. ■ Patients should be monitored every 3 months for 2 years and annually thereafter for formation of IgG antibodies. Testing for IgG titers may also be considered if a patient develops hypersensitivity or other immune-mediated reactions. Testing for IgE antibodies may also be considered. ■ Patients who develop IgG antibodies may be evaluated for inhibition of enzyme activity or cellular uptake of enzyme. ■ There is no marketed test for antibodies against alglucosidase alfa; contact the Genzyme Corporation for further information.

Patient Education:

Report early symptoms of a hypersensitivity or infusion reaction promptly (e.g., chills or rigors, difficulty breathing, fever, flushing, headache, itching, rash, shortness of breath). ■ Genzyme has established a registry and encourages all patients to participate to further evaluate the effects of therapy with possible long-term follow-up.

Maternal/Child:

The continuation of treatment for Pompe disease during pregnancy should be individualized to the pregnant woman. Untreated Pompe disease may result in worsening disease symptoms (e.g., worsening respiratory and musculoskeletal symptoms) in pregnant women. A Pompe disease registry has been established. Enrollment is encouraged to better understand the variability and progression of Pompe disease and to continue to monitor and evaluate the long-term treatment effects of alglucosidase alfa as well as the effect of alglucosidase alfa on pregnant women and their offspring; contact manufacturer. ■ Use caution during breast-feeding. Alglucosidase alfa is present in human milk. To minimize infant exposure, a breast-feeding mother may pump and discard breast milk produced during the 24 hours after administration of alglucosidase alfa. ■ Clinical trials included treatment of pediatric patients 1 month to 3.5 years of age. Other clinical trials have been conducted on pediatric patients up to 16 years of age (juvenile-onset Pompe disease); however, safety and effectiveness have not been established in this patient group.

Elderly:

Older patients were not included in studies; response in the elderly is unknown.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

The most common serious adverse reactions observed were catheter-related infections, fever, gastroenteritis, pneumonia, respiratory distress, respiratory failure, and respiratory syncytial virus infection. The most common adverse reactions requiring intervention were infusion reactions. The most serious adverse reactions reported were anaphylactic reactions, acute cardiorespiratory failure, and cardiac arrest. The most common adverse reactions requiring intervention in clinical trials were infusion reactions. Infusion-related and/or hypersensitivity reactions may be mild, moderate, or severe, and S/S may include acute cardiorespiratory failure, anaphylaxis, angioneurotic edema, bradycardia, bronchospasm, cardiac arrest, cold sweat, cough, cyanosis, decreased oxygen saturation, dyspnea, erythema, flushing, hypertension, hypotension, hypoxia, nodal rhythm, pallor, periorbital edema, peripheral coldness, pruritus, rales, rash, tachycardia, tachypnea, tightness of the throat, urticaria, ventricular extrasystoles, and/or wheezing. Commonly occurring side effects include cough, decreased oxygen saturation, diarrhea, headache, malaise, otitis media, pharyngitis, rash, rhinitis, upper abdominal pain, upper respiratory infections, and vomiting. Heart and lung failure and anaphylactic reactions, including anaphylactic shock, may be fatal.

Post-Marketing:

Acute cardiorespiratory failure (possibly associated with fluid overload), hypersensitivity reactions (including anaphylaxis), recurrent flu-like illness (e.g., arthralgia, chills, fatigue, fever, or myalgia) after completion of infusions and lasting 1 to 3 days, systemic and cutaneous immune-mediated reactions (including nephrotic syndrome, proteinuria, and necrotizing skin lesions).

ANTIDOTE

Keep physician informed of side effects; may be treated symptomatically if indicated. If an infusion reaction occurs, reduce rate or discontinue alglucosidase alfa until symptoms subside. Additional antipyretics (e.g., acetaminophen), antihistamines (e.g., diphenhydramine), or corticosteroids (e.g., dexamethasone) may be indicated. With additional premedication and/or a reduction in the rate of infusion, patients may be able to continue treatment. If a severe infusion, hypersensitivity, or anaphylactic reaction occurs, discontinue alglucosidase alfa immediately and treat as indicated. Cardiopulmonary resuscitation, mechanical ventilatory support, oxygen supplementation, IV fluids, antihistamines (e.g., diphenhydramine), inhaled beta-adrenergic agonists (e.g., albuterol), epinephrine, and IV corticosteroids (e.g., hydrocortisone sodium succinate [Solu-Cortef]) have been required. Patients with recurrent flulike illness have been successfully rechallenged using lower doses and/or additional premedication.

ALLOPURINOL SODIUM

(al-oh-**PYOUR**-ih-nohl **SO**-dee-um)
Aloprim
Antigout
Antihyperuricemic
Antineoplastic adjunct
pH 11.1 to 11.8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Allopurinol:

IV and oral doses are therapeutically equivalent. Oral dose can replace an IV dose at any time. See Monitor.

200 to 400 mg/M^2/day as a single infusion or in equally divided doses at 6-, 8-, or 12-hour intervals (50 to 100 mg/M^2 every 6 hours, 67 to 133 mg/M^2 every 8 hours, or 100 to 200 mg/M^2 every 12 hours). Total dose should not exceed 600 mg/day.

PEDIATRIC DOSE

Recommended starting dose is 200 mg/M^2/day. Usually given in equally divided doses at 6- to 8-hour intervals (50 mg/M^2 every 6 hours or 67 mg/M^2 every 8 hours). Another source says the daily dose may be given at 6-, 8-, or 12-hour intervals or as a single daily infusion. Studies found no significant difference in dose response in pediatric patients. See comments in Usual Dose.

DOSE ADJUSTMENTS

In patients with impaired renal function not on dialysis, reduce dose based on CrCl according to the following chart.

Allopurinol Dosing in Impaired Renal Function

CrCl (mL/min)	Dose
10-20 mL/min	200 mg daily
3-10 mL/min	100 mg daily
<3 mL/min	100 mg daily at extended intervals (more than 24 hr if necessary)

Treat with the lowest effective dose to minimize side effects. ■ Dose with normal renal function may be increased or decreased based on electrolytes and serum uric acid levels. ■ Lower doses and/or extended intervals may be required in the elderly; consider potential for decreased organ function, concomitant disease, or other drug therapy. ■ See Drug/Lab Interactions.

DILUTION

Available as a single-dose vial containing 500 mg of allopurinol. Reconstitute with 25 mL of SWFI (yields 20 mg/mL). Swirl until completely dissolved. Must be further diluted with NS or D5W. Maximum concentration for administration is 6 mg/mL. 19 mL of additional diluent per 20 mg (1 mL) yields 1 mg/mL, 9 mL of additional diluent yields 2 mg/mL, and 2.3 mL of additional diluent yields 6 mg/mL.

Storage:

Store unopened vials at CRT. Do not refrigerate the reconstituted and/or diluted product; begin infusion within 10 hours of reconstitution.

COMPATIBILITY

Manufacturer recommends administering sequentially and flushing before and after administration. Manufacturer lists the following drugs as **incompatible:** amikacin, amphotericin B (conventional), carmustine, cefotaxime, chlorpromazine, clindamycin, cytarabine, dacarbazine, daunorubicin, diphenhydramine, doxorubicin, doxycycline, floxuridine, gentamicin, idarubicin, imipenem-cilastatin, mechlorethamine, meperidine, methylprednisolone, metoclopramide, minocycline, nalbuphine, ondansetron, prochlorperazine, promethazine, sodium bicarbonate, streptozocin, tobramycin, vinorelbine. ***Do not use solutions containing sodium bicarbonate.***

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Manufacturer's recommendation not available. A maximum dose should take at least ½ to 1 hour or more based on volume with diluent and patient comfort and/or requirements. Include in hydration fluids. See Compatibility.

ACTIONS

A xanthine oxidase inhibitor. Metabolized to oxypurinol. Acts on purine catabolism without disrupting the biosynthesis of purines. Reduces the production of uric acid by inhibiting the biochemical reactions immediately preceding its formation. Decreases uric acid concentrations in both serum and urine. Prevents or decreases urate deposition, decreasing the occurrence or progression of gout or urate nephropathy. Reduction of serum uric acid concentration occurs in 2 to 3 days. Peak concentrations are related to dose. Pharmacokinetic and plasma profiles of allopurinol and oxypurinol, as well as half-lives and systemic clearance, are similar with IV or oral administration. Systemic exposure to oxypurinol is also similar by both routes at each dose level. Cleared by glomerular filtration; some oxypurinol is reabsorbed in the kidney tubules. Secreted in breast milk.

INDICATIONS AND USES

Management of patients with leukemia, lymphoma, and solid tumor malignancies who are receiving cancer therapy that causes elevations of serum and urinary uric acid levels and who cannot tolerate oral therapy. Consider prophylactic use before initiation of and during chemotherapy in patients who are NPO, are nauseated and vomiting, or have malabsorption problems, dysphagia, or GI tract dysfunctions. Used prophylactically before the initiation of and during chemotherapy to prevent hyperuricemia caused by tumor lysis syndrome (TLS) and its sequela, acute uric acid nephropathy (AUAN).

Unlabeled uses:

Preservation of cadaveric kidneys for transplantation.

CONTRAINDICATIONS

Any patient who has had a severe reaction to allopurinol (usually a hypersensitivity reaction).

PRECAUTIONS

For IV infusion only. ■ A skin rash or other beginning signs of hypersensitivity may be followed by exfoliative, urticarial, and purpuric lesions; Stevens-Johnson syndrome; generalized vasculitis; irreversible hepatotoxicity; and/or rarely death. ■ Incidence of hypersensitivity reactions may be increased in patients with decreased renal function who are receiving concurrent thiazides (e.g., chlorothiazide); use with caution. ■ See Drug/Lab Interactions.

Monitor:

Whenever possible, begin allopurinol therapy 24 to 48 hours before the start of chemotherapy known to cause tumor cell lysis (including adrenocorticosteroids). ■ Monitor serum uric acid levels and electrolytes before and during therapy. Monitor serum uric acid levels to determine dose and frequency required to maintain uric acid levels within the normal range. ■ Hydration with 3,000 mL/M^2/day (twice the level of maintenance fluid replacement) is recommended to promote a high volume of urine output (more than 2 L/day in adults) with low urate concentration. ■ Maintain urine at neutral or slightly alkaline pH. To increase solubility of uric acid, alkalinity of urine may be increased with sodium bicarbonate. ■ Monitor renal and hepatic systems before and during therapy. ■ Monitoring of liver function suggested in patients with pre-existing liver disease, in patients with increases in liver function tests, and in patients who develop anorexia, pruritus, or weight loss. ■ Observe for symptoms of TLS (e.g., hyperuricemia, hyperkalemia, hyperphosphatemia, and hypocalcemia). If untreated, may develop AUAN leading to renal failure requiring hemodialysis. ■ Bone marrow suppression has been reported; monitor CBC periodically.

Patient Education:

Maintain adequate hydration, avoid alcoholic drinks, and report nausea and vomiting and decreased urine production. ■ Report promptly blood in the urine, painful urination, irritation of the eyes, skin rash, or swelling of the lips or mouth. ■ Major acute toxicities may be allergic or renal. ■ May cause drowsiness; use caution in activities that require alertness. Request assistance for ambulation.

Maternal/Child:

Category C: potential benefits must justify potential risks to fetus. ■ Use caution if required during breast-feeding.

Elderly:

Lower-end initial doses or extended intervals may be appropriate in the elderly; see Dose Adjustments.

DRUG/LAB INTERACTIONS

May increase toxicity of **didanosine**; concurrent use not recommended. ■ Inhibits metabolism and increases effects and toxicity of **thiopurines** (e.g., azathioprine, mercaptopurine). Reduce dose of thiopurine to one-third to one-fourth. ■ **Uricosuric agents** (e.g., sulfinpyrazone, probenecid, colchicine) may increase elimination of active metabolites of allopurinol; may increase urinary excretions of uric acid. ■ Prolongs half-life of **dicumarol;** monitor PT or PTT and adjust anticoagulant dose as indicated. ■ Frequency of skin rash increased with **ampicillin/amoxicillin.** ■ Bone marrow suppression may be increased when given concurrently with **cytotoxic agents** (e.g., cyclophosphamide); risk of bleeding or infection may be increased. ■ May prolong half-life of **chlorpropamide**. ■ Hypersensitivity reactions may be increased with **ACE inhibitors or thiazide diuretics**. ■ Concurrent use with **cyclosporine** may increase cyclosporine serum levels. A reduced dose of cyclosporine may be indicated; monitoring of cyclosporine serum levels suggested. ■ May decrease clearance and increase toxicity of **theophyllines**.

SIDE EFFECTS

Fewer than 1% of patients have had side effects directly attributable to allopurinol. Most were hypersensitivity reactions (e.g., nausea and vomiting, rash, and renal failure/insufficiency) and of mild to moderate severity. Xanthine crystalluria has been rarely reported in long-term therapy with oral allopurinol.

ANTIDOTE

Discontinue allopurinol at the first sign of skin rash or any other allergic reaction. Do not restart. Keep physician informed of all side effects. Symptoms of TLS require immediate intervention and correction of electrolyte abnormalities to avoid kidney damage. Treat hypersensitivity reactions as indicated; may require epinephrine, diphenhydramine, corticosteroids, and/or oxygen. Allopurinol is dialyzable, but effectiveness of hemodialysis or peritoneal dialysis in an overdose is not known.

ALPHA$_1$-PROTEINASE INHIBITOR (HUMAN)

(**AL**-fah **PRO**-teen-ayse in-**HIB**-ih-ter [**HU**-man])

Alpha$_1$-antitrypsin, Alpha$_1$-PI, Aralast NP, Glassia, Prolastin-C, Zemaira

Alpha$_1$-antitrypsin replenisher

pH 7.2 to 7.8 (Aralast NP) ■ pH 6.6 to 7.4 (Prolastin-C)

USUAL DOSE

Pretreatment:

See Precautions.

Manufacturers of Prolastin-C recommend immunizing every patient against hepatitis B before administration. If immediate treatment is required, give a single dose of hepatitis B immune globulin (human) 0.06 mL/kg IM at the same time as the initial dose of hepatitis B vaccine.

Alpha$_1$-proteinase inhibitor:

60 mg/kg once a week as an infusion.

DILUTION

All preparations:

Bring components to room temperature (diluent [SWFI], lyophilized preparation of alpha$_1$-PI, or ready-to-use solution). Must be used within 3 hours of reconstitution or entry into vial. Must be filtered before or during administration.

Aralast NP and Prolastin-C:

Insert one end of the double-ended transfer needle (shortest end for Prolastin-C) into the diluent. Invert the bottle of diluent and insert the other end of the transfer needle at a 45-degree angle into the alpha$_1$-PI; diluent will be drawn into the alpha$_1$-PI by a vacuum. Remove the diluent bottle and transfer device.

Aralast NP—

Allow the reconstituted solution to stand until contents appear to be in solution, then swirl gently to completely dissolve. May take 5 to 10 minutes. ***Do not shake or invert vial until ready to withdraw contents.*** Solution should be colorless to slightly yellow to yellowish-green. A few small visible particles may occasionally remain and will be removed by the microaggregate filter. Reconstituted product from several vials may be pooled into an empty, sterile IV solution container. Use the sterile 20-micron filter provided for transfer.

Prolastin-C—

Swirl vigorously for 10 to 15 seconds immediately after adding diluent to thoroughly break up cake, then swirl continuously until the powder is completely dissolved. Some foaming will occur. Reconstituted product from several vials may be pooled into an empty, sterile IV solution container. If particles are visible, remove by passing through a sterile filter (e.g., 15-micron filter [not supplied]) used for administering blood products.

Glassia:

Available as a single-use vial containing 1 Gm of functional alpha$_1$-PI in 50 mL of ready-to-use solution. Solution should be clear and colorless to yellow-green. Do not use if product is cloudy. Infusion can be made directly from the vial, or vials may be pooled in an empty, sterile IV container. When infusing directly from the vial, use a vented spike adapter and a 5-micron in-line filter (neither is supplied). When infusing from a sterile IV container, use a vent filter (not supplied) to withdraw Glassia from the vial, and then use the supplied 5-micron filter needle to transfer Glassia into the infusion container. Attach an IV administration set and administer through an additional 5-micron in-line filter (not supplied).

Zemaira:

Insert the white end of the double-ended transfer needle into the center of the upright diluent vial. Invert the diluent vial and insert the green end of the double-ended transfer needle into the center of the product vial. Use minimum force. Diluent will be drawn into the alpha$_1$-PI by a vacuum. Wet the lyophilized cake completely by gently tilting the product vial. Do not allow the air inlet filter to face downward, and use care not to lose the vacuum. Remove the diluent bottle and transfer device. Gently swirl until the powder is completely dissolved. May take 5 to 10 minutes. ***Do not shake or invert vial until ready to withdraw contents.*** Reconstituted product from several vials may be pooled into an empty, sterile IV solution container. Administer through an infusion set with a 5-micron in-line filter (not supplied).

Aralast NP will yield a 0.5 Gm/25 mL vial or a 1 Gm/50 mL vial (20 mg/mL).
Glassia will yield a 1 Gm/50 mL vial (20 mg/mL).
Prolastin-C will yield a 1 Gm/20 mL vial (50 mg/mL).
Zemaira will yield a 1 Gm/20 mL vial (50 mg/mL).

Filters:

All products must be filtered before or during administration. Manufacturers supply either a filter needle to withdraw alpha$_1$-PI from the vial or may supply an in-line filter (to be used in the IV line or for pooling); see Dilution for other filter requirements.

Storage:

Refrigerate ***Glassia*** in carton until use. Contains no preservatives and no latex. ***Aralast NP and Prolastin-C*** should be stored at temperatures not to exceed 25° C (77° F). ***Zemaira*** may be refrigerated before reconstitution or stored at temperatures up to 25° C (77° F). ***All Preparations:*** Avoid freezing. Do not use after expiration date on vials. Must be used within 3 hours of reconstitution or entry into vial.

COMPATIBILITY

Manufacturers state, “Should be given alone, without mixing with other agents or diluting solutions.”

RATE OF ADMINISTRATION

Aralast NP:

Do not exceed 0.08 mL/kg/min.

Prolastin-C, Zemaira:

0.08 mL/kg/min is recommended.

Glassia:

Do not exceed 0.04 mL/kg/min.

If an infusion reaction or other adverse effects occur, a reduced rate or interruption of the infusion may be indicated until symptoms subside; see Side Effects and Antidote.

ACTIONS

Aralast NP, Prolastin-C, Zemaira are sterile, stable, lyophilized preparations.

Glassia is a ready-to-use solution. All are obtained from human plasma. Increases and maintains functional levels of alpha$_1$-PI in the epithelial lining of the lower respiratory tract. Provides adequate antineutrophil elastase activity in the lungs of individuals with alpha$_1$-antitrypsin deficiency. Weekly infusions of alpha$_1$-PI usually maintain serum levels above a target threshold of 11 micromoles. Numerous processes employed during manufacture to eliminate potential for viral transmission from human plasma; see Precautions.

INDICATIONS AND USES

Treatment of congenital alpha$_1$-antitrypsin deficiency, a potentially fatal deficiency; used for chronic replacement (augmentation and maintenance therapy) only in individuals with alpha$_1$-antitrypsin deficiency and selected types of clinically demonstrated emphysema.

CONTRAINDICATIONS

Individuals with selective IgA deficiencies (IgA level less than 15 mg/dL for **Aralast NP**) who have known antibodies against IgA (anti-IgA antibodies). IgA may be present and severe reactions, including anaphylaxis, can occur. ■ Known hypersensitivity to any alpha$_1$-PI product or any product components.

PRECAUTIONS

For IV use only. Confirm diagnosis of congenital alpha$_1$-antitrypsin deficiency with selected clinically demonstrated emphysema. ■ May contain trace amounts of IgA. Patients with selective or severe IgA deficiency and with known antibodies to IgA have a greater risk for developing severe hypersensitivity and anaphylactic reactions; see Contraindications. ■ Each unit of plasma is tested and found nonreactive to HIV antibody, Creutzfeldt-Jakob disease, hepatitis B surface antigen, and hepatitis C. Transmission of these viruses is still possible. ■ Will increase plasma volume; use caution in patients at risk for circulatory overload. ■ Long-term effects from continued use are not known. ■ Individuals severely deficient in endogenous alpha$_1$-PI are unable to maintain an adequate antiprotease defense and are subject to more rapid proteolysis of the alveolar walls leading to chronic lung disease. Pulmonary infections, including pneumonia and acute bronchitis, are common in these individuals.

Monitor:

Monitor V/S and observe patient continuously throughout infusion. ■ Blood levels of alpha$_1$-PI have been maintained above the functional level of 80 mg/dL with this replacement therapy. Serum levels determined by commercial immunologic assays may not reflect actual functional alpha$_1$-PI levels. ■ Assess lung sounds and rate and quality of respirations before each infusion. ■ Monitor for S/S of a hypersensitivity reaction (e.g., dyspnea, flushing, hypotension, rash, tachycardia); emergency equipment, medications, and supplies must be available.

Patient Education:

Inform of risks and of safety precautions taken during manufacturing process. ■ Note changes in breathing pattern or sputum production; avoid smoking. ■ Report S/S of a hypersensitivity reaction promptly (e.g., dyspnea, faintness, hives, hypotension, tightness of the chest). ■ Report S/S of parvovirus B19 (e.g., chills, drowsiness, fever, and runny nose, followed 2 weeks later by a rash and joint pain). Parvovirus B19 may be more serious in pregnant women and immune-compromised individuals.

Maternal/Child:

Category C: use in pregnancy only when clearly needed. May present risk to fetus; benefits must justify risks. ■ Safety for use during breast-feeding not established; effects unknown. ■ Safety for use in pediatric patients not established.

Elderly:

Differences in response compared to younger adults not known. As for all patients, dosing for elderly patients should be appropriate to their overall situation.

DRUG/LAB INTERACTIONS

No specific information available; see Compatibility.

SIDE EFFECTS

All formulations:

Consider risk potential for contracting AIDS, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C. Hypersensitivity reactions, including anaphylaxis, chills, dyspnea, hypotension, rash, and tachycardia, have been reported; see Contraindications.

Aralast NP:

Cough, headache, musculoskeletal discomfort, and pharyngitis are most common. Asthma, back pain, bloating, bronchitis, dizziness, pain, peripheral edema, rash, rhinitis, sinusitis, somnolence, and viral infection may occur.

Glassia:

Dizziness and headache are most common. Chest discomfort, cough, increased hepatic enzymes, sinusitis, and URI have been reported. Cholangitis, exacerbation of COPD, and severe headache may occur.

Prolastin-C:

Chills, headache, hot flush, pruritus, and rash were most common. A severe abdominal and extremity rash occurred in one patient and recurred in two patients on rechallenge.

Zemaira:

Asthenia, bronchitis, chest pain, cough, dizziness, fever, headache, injection site pain and/or hemorrhage, paresthesia, pruritus, rhinitis, sinusitis, sore throat, and upper respiratory infections may occur.

ANTIDOTE

All side effects except potential transmission of viral diseases usually subside spontaneously. Keep the physician informed. If side effects occur, interrupt or discontinue infusion until symptoms subside, then resume at a tolerated rate. Discontinue alpha$_1$-PI and treat anaphylaxis (antihistamines, epinephrine, corticosteroids) as indicated. Resuscitate as necessary.

ALPROSTADIL BBW

(al-**PROSS**-tah-dill)

Prostaglandin E$_1$, Prostin VR Pediatric

Prostaglandin (ductus arteriosus patency adjunct)

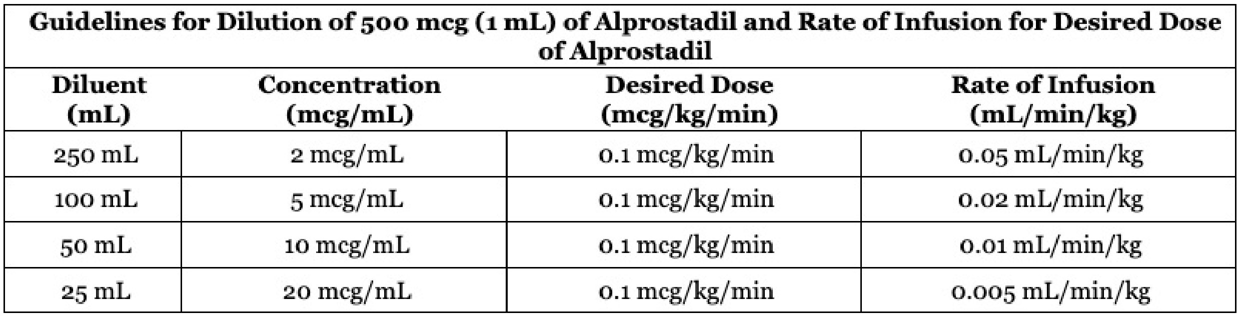
USUAL DOSE

Pediatric patients:

Begin with 0.05 to 0.1 mcg/kg/min. When therapeutic response is achieved, reduce infusion rate in increments to the lowest dose that maintains the response (e.g., reduce from 0.1 to 0.05 or from 0.025 to 0.01 mcg/kg/min). If necessary, dose may be increased gradually to a maximum of 0.4 mcg/kg/min. Generally these higher rates do not produce greater effects. May be given through infusion in a large vein or, if necessary, through an umbilical artery catheter placed at the ductal opening.

DILUTION

Each 500 mcg (1 mL) must be further diluted with NS or D5W. When using a volumetric infusion chamber, the appropriate amount of IV infusion solution should be added to the chamber first. The undiluted alprostadil should then be added to the IV infusion solution, avoiding direct contact of the undiluted solution with the wall of the volumetric infusion chamber; see Compatibility. Various volumes of infusion solution may be used depending on infusion pump capabilities and desired infusion rate.



Guidelines for Dilution of 500 mcg (1 mL) of Alprostadil and Rate of Infusion for Desired Dose of Alprostadil

Diluent (mL)	Concentration (mcg/mL)	Desired Dose (mcg/kg/min)	Rate of Infusion (mL/min/kg)
250 mL	2 mcg/mL	0.1 mcg/kg/min	0.05 mL/min/kg
100 mL	5 mcg/mL	0.1 mcg/kg/min	0.02 mL/min/kg
50 mL	10 mcg/mL	0.1 mcg/kg/min	0.01 mL/min/kg
25 mL	20 mcg/mL	0.1 mcg/kg/min	0.005 mL/min/kg

Storage:

Refrigerate until dilution. Prepare fresh solution for administration every 24 hours.

COMPATIBILITY

Manufacturer states that undiluted alprostadil may interact with the plastic sidewalls of the volumetric infusion chamber, causing a change in the appearance of the chamber and creating a hazy solution. Should this occur, the solution and the volumetric infusion chamber should be replaced; see Dilution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Usual Dose. Infusion pump capable of delivering 0.005, 0.01, 0.02, or 0.05 mL/min/kg required. Use for the shortest time possible at the lowest rate therapeutically effective. Decrease rate of infusion *stat* if a significant fall in arterial pressure occurs.

ACTIONS

A naturally occurring acidic lipid. A prostaglandin. Has various pharmacologic effects, including vasodilation, inhibition of platelet aggregation, and stimulation of the intestinal and uterine smooth muscle. Lowers blood pressure by decreasing peripheral resistance. A reflex increase in cardiac output and heart rate accompanies the reduction in blood pressure. Smooth muscle of the ductus arteriosus is susceptible to alprostadil's relaxing effect. Infants with congenital defects that restrict the pulmonary or systemic blood flow may benefit from alprostadil infusion. In some infants with restricted pulmonary blood flow, an increase in blood PO_2 was observed. In some infants with restricted systemic blood flow, an increase in pH in those who were acidotic, an increase in SBP, and a decrease in the ratio of pulmonary artery pressure to aortic pressure were seen. Rapid metabolism by oxidation (80% in one pass through the lungs) necessitates administration by continuous infusion. Remainder excreted as metabolites in the urine.

INDICATIONS AND USES

Temporarily maintain the patency of the ductus arteriosus until corrective or palliative surgery can be performed on neonates who have congenital heart defects and who depend on the patent ductus for survival. Such congenital heart defects include pulmonary atresia, pulmonary stenosis, tricuspid atresia, tetralogy of Fallot, interruption of the aortic arch, coarctation of the aorta, or transposition of the great vessels. ■ Used by intercavernosal injection to treat impotence.

CONTRAINDICATIONS

None known.

PRECAUTIONS

Usually administered by trained personnel in pediatric intensive care facilities. ■ Establish a diagnosis of cyanotic heart disease (restricted pulmonary blood flow). Not indicated for infant respiratory distress syndrome (hyaline membrane disease). ■ Response is poor in infants with Po_2 values of 40 torr or more or those more than 4 days old. More effective with lower Po_2. ■ Apnea has been experienced in 10% to 12% of treated neonates; see Monitor. ■ Use caution in neonates with bleeding tendencies; inhibits platelet aggregation. ■ Administration of alprostadil to neonates may result in gastric outlet obstruction secondary to antral hyperplasia. Appears to be related to duration of therapy and cumulative dose. Risk of long-term infusion should be weighed against the possible benefits in a critically ill neonate; see Monitor. ■ Cortical proliferation of the long bones has been observed in infants during long-term infusions. May regress after withdrawal of drug.

Monitor:

Monitor respiratory status continuously. Ventilatory assistance must be immediately available. May cause apnea, especially in infants under 2 kg. Apnea usually appears during the first hour of infusion. ■ Monitor arterial pressure intermittently by umbilical artery catheter, auscultation, or Doppler transducer. Decrease rate of infusion *stat* if a significant fall in arterial pressure occurs. ■ Decrease or stop infusion if infant develops increased respiratory distress; bleeding, bruising, or hematoma formation; or sudden changes in cardiac status (e.g., decreased BP, bradycardia, cardiac arrest, cyanosis). ■ Measure effectiveness with increase of Po_2 in infants with restricted pulmonary blood flow and increase of BP and blood pH in infants with restricted systemic blood flow. ■ Monitor for evidence of antral hyperplasia and gastric outlet obstruction in neonates receiving more than 120 hours of therapy at recommended doses.

DRUG/LAB INTERACTIONS

No drug interactions have been reported between alprostadil and the therapy that is standard in neonates with restricted pulmonary or systemic blood flow. Standard therapy includes **antibiotics** such as penicillin or gentamicin; **vasopressors** such as dopamine and isoproterenol; **cardiac glycosides**; and **diuretics** such as furosemide. ■ Inhibits **platelet aggregation.**

SIDE EFFECTS

Apnea, bradycardia, cardiac arrest, cerebral bleeding, cortical proliferation of long bones, diarrhea, DIC, edema, fever, flushing, hyperextension of the neck, hyperirritability, hypokalemia, hypotension, hypothermia, seizures, sepsis, tachycardia. Many other side effects have occurred in 1% or less of infants receiving alprostadil.

Overdose:

Apnea, bradycardia, fever, flushing, hypotension.

ANTIDOTE

Notify physician of all side effects. Discontinue immediately if apnea occurs. Institute emergency measures. If infusion is restarted, use extreme caution. Decrease or stop infusion if infant develops increased respiratory distress; bleeding, bruising, or hematoma formation; or sudden changes in cardiac status (e.g., decreased BP, bradycardia, cardiac arrest, cyanosis). Decrease rate if pyrexia, hypotension, or fall in arterial pressure occurs.

ALTEPLASE

(**AL**-teh-playz)

Activase, rt-PA 🍁 , Tissue Plasminogen Activator, tPA ■ Cathflo Activase
Thrombolytic agent
pH 7.3

USUAL DOSE

Pretreatment:

Baseline studies required; see Monitor.

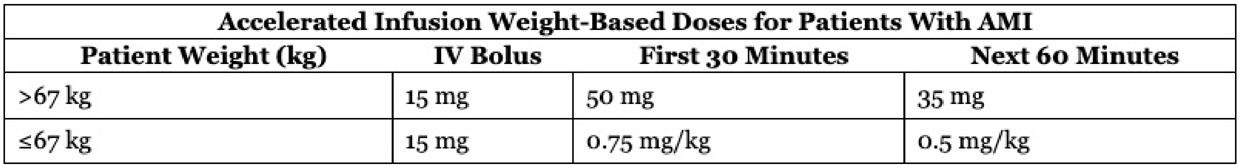
Selected indications (e.g., acute ischemic stroke, acute myocardial infarction [AMI] in patients weighing less than 65 or 67 kg) require exact weight-adjusted dosing. To deliver an accurate dose without possibility of overdose, calculate desired dose and **withdraw** any amount ***NOT*** needed from a 50- or 100-mg vial and **discard**. In all situations follow total dose with at least 30 mL of NS or D5W through the IV tubing to ensure administration of total dose.

Acute Myocardial Infarction

Administer as soon as possible after onset of symptoms. Total dose is based on patient weight and should not exceed 100 mg regardless of selected administration regimen (accelerated infusion and 3-hour infusion are outlined in the following sections).

Accelerated infusion:

Recommended accelerated infusion dose consists of an IV bolus over 1 to 2 minutes followed by an IV infusion as shown in the following chart.



Accelerated Infusion Weight-Based Doses for Patients With AMI

Patient Weight (kg)	IV Bolus	First 30 Minutes	Next 60 Minutes
>67 kg	15 mg	50 mg	35 mg
≤67 kg	15 mg	0.75 mg/kg	0.5 mg/kg

The safety and efficacy of accelerated infusion of alteplase have only been investigated with concomitant administration of heparin and aspirin. See comments under Usual Dose.

3-hour infusion:

For patients weighing 65 kg or more, administer a total dose of 100 mg titrated over 3 hours as an IV infusion. Initially, administer 60 mg over the first hour (with 6 to 10 mg of this administered as a bolus over 1 to 2 minutes). Follow with 20 mg/hr for 2 hours. For smaller patients (less than 65 kg), calculate total dose using 1.25 mg/kg of body weight administered over 3 hours (with 0.075 mg/kg administered as a bolus over 1 to 2 minutes). Follow with 0.675 mg/kg over the first hour and 0.25 mg/kg/hr for 2 hours.

Weight-based doses are shown in the following chart. See comments under Usual Dose.

3-Hour Infusion Weight-Based Doses for Patients With AMI				
Patient Weight (kg)	**Bolus**	**Rest of 1st Hour**	**2nd Hour**	**3rd Hour**
≥65 kg	6 to 10 mg	50 to 54 mg	20 mg	20 mg
<65 kg	0.075 mg/kg	0.675 mg/kg	0.25 mg/kg	0.25 mg/kg

Acute Ischemic Stroke

Administer as soon as possible but within 3 hours after onset of symptoms. Perform non–contrast-enhanced CT or MRI before administration to rule out intracranial bleed. Recommended dose is 0.9 mg/kg. Do not exceed the maximum dose of 90 mg. See comments in Usual Dose. Give a bolus of 10% of the calculated dose over 1 minute followed by balance of calculated dose (90%) as an infusion evenly distributed over 60 minutes. Do not give aspirin, heparin, or warfarin for 24 hours; see Precautions.

Pulmonary Embolism

100 mg administered over 2 hours as an IV infusion. Begin parenteral anticoagulation near the end of or immediately following the alteplase infusion when the partial thromboplastin time (PTT) or thrombin time (TT) returns to twice normal or less.

Central Venous Access Device (CVAD) Occlusions, Cathflo Activase

See Rate of Administration, Precautions, Monitor, and Maternal/Child.

Patient weight 30 kg or greater:

Instill 2 mg in 2 mL into the occluded catheter.

Patient weight less than 30 kg:

Instill 110% of the internal lumen volume of the occluded catheter into the occluded catheter. Do not exceed 2 mg in 2 mL.

Attempt to aspirate blood from the catheter after 30 minutes of dwell time. If catheter function has been restored, aspirate 4 to 5 mL of blood in patients equal to or greater than 10 kg or 3 mL of blood in patients less than 10 kg to remove Cathflo Activase and residual clot, then gently irrigate the catheter with NS.

If catheter function has not been restored (unable to aspirate blood), allow the first dose to remain in the catheter for 90 additional minutes of dwell time and then attempt to aspirate again (total elapsed time is 120 minutes). If catheter function has been restored, aspirate and irrigate as above. If function has not been restored, a second dose may be instilled and the dwell time and aspiration process repeated.

DILUTION

Myocardial infarction, stroke, and pulmonary embolism:

Must be reconstituted with SWFI without preservatives (provided by manufacturer). Available in 50- and 100-mg vials. May be administered as reconstituted solution at 1 mg/mL or further diluted immediately before administration in an equal volume of NS or D5W to yield a concentration of 0.5 mg/mL using either polyvinyl chloride bags or glass vials. Slight foaming is expected; let stand for several minutes to dissipate large bubbles. Do not shake. Mix by swirling or slow inversion; avoid agitation during dilution.

50-mg vial:

Use a large-bore (18-gauge) needle and syringe to direct the stream of provided diluent (SWFI) into the lyophilized cake. A vacuum must be present when the diluent is added to the powder for injection. Do not use if vacuum is not present.

Bolus dose can be given when indicated by withdrawing the calculated dose from the infusion and injecting it through a med port. When obtaining the bolus dose, ***do not*** prime syringe with air; insert needle into the alteplase vial stopper to withdraw dose. Alternately, the IV pump can be programmed to deliver the appropriate volume as a bolus at the initiation of the infusion. Administer balance of dose, using either a polyvinyl chloride bag or glass vial and infusion set. Adjust pump rate as required. Complete by flushing tubing with IV solution.

100-mg vial:

Does not contain a vacuum. Diluent and transfer device provided. Insert one end of transfer device into upright vial of diluent (do not invert diluent vial yet). Hold alteplase vial upside down and push center of vial down onto piercing pin. Now invert vials and allow diluent to flow into alteplase. Small amount (0.5 mL) of diluent will not transfer. Swirl gently to dissolve. Do not shake. Process takes several minutes. Remove any quantity of drug in excess of that specified for patient treatment; see Usual Dose.

Bolus dose can be given when indicated by IV injection through a med port or by programming the IV pump to deliver the appropriate volume as a bolus at the initiation of the infusion as described previously. When withdrawing the bolus dose from a 100-mg vial, the needle should be inserted away from the puncture mark made by the transfer device. Administer the balance of dose by inserting an infusion set into puncture site created by piercing pin. Hang by plastic capping on bottom of vial. Prime tubing with alteplase and administer. Adjust pump rate of delivery as required. Complete by flushing tubing with IV solution.

Cathflo Activase for CVAD occlusion:

Supplied as a sterile lyophilized powder in 2-mg vials. Must be reconstituted with 2.2 mL of SWFI without preservatives. Direct diluent stream into the powder. Allow to stand undisturbed until large bubbles dissipate; may foam slightly. Mix by swirling gently; do not shake. Should be completely dissolved within 3 minutes. Final concentration is 1 mg/mL. If the 2-mg vials are not available, some pharmacies dilute 50 mg of alteplase with 50 mL of SWFI without preservatives (1 mg/mL). Withdraw 2.2 mL (2.2 mg) into 2- or 5-mL sterile disposable syringes. In studies these were transferred to sterile glass vials and frozen. Defrost and use as needed (22 prepared doses).

Filters:

Specific information not available.

Storage:

Systemic alteplase:

Protect from light in cartons. May be stored at CRT or refrigerated before and/or after reconstitution. Manufacturer recommends reconstitution immediately before use. Must be used within 8 hours of reconstitution. Discard unused solution. Stable as a 0.5 mg/mL solution in NS or D5W for 8 hours at CRT.

Cathflo Activase:

Refrigerate unopened vials; protect from light during extended storage. Reconstitution immediately before use is recommended, but solution may be used up to 8 hours after reconstitution if refrigerated at 2° to 30° C (36° to 46° F). Do not use beyond expiration date on vial. Discard unused solution.

COMPATIBILITY

Manufacturer states, "No other medication should be added to infusion solutions containing alteplase"; see Dilution.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Systemic alteplase:

See specific rates for each diagnosis under Usual Dose. In all situations use an infusion pump (preferred) or a metriset with microdrip (60 gtt/mL) and IV tubing to facilitate accurate administration. Flushing of IV line required. NS preferred for flushing of IV line.

Cathflo Activase:

Avoid excessive pressure or force while attempting to clear catheters; see Usual Dose, Precautions, and Monitor.

ACTIONS

A tissue plasminogen activator and enzyme produced by recombinant DNA technology. It binds to fibrin in a thrombus and converts plasminogen to plasmin. This initiates local fibrinolysis and dissolution of the clot. Onset of action is prompt. Cleared from the plasma by the liver within 5 (50%) to 10 (80%) minutes after the infusion is discontinued. Some fibrinolytic activity may persist for up to 1 hour after completion of the infusion.

Cathflo Activase:

When Cathflo Activase is administered for restoration of function to central venous access devices according to the manufacturer's instructions, circulating plasma levels of alteplase are not expected to reach pharmacologic concentrations.

INDICATIONS AND USES

Systemic alteplase:

Use in acute myocardial infarction (AMI) for the reduction of the incidence of congestive heart failure and the reduction of mortality associated with AMI. ■ Treatment of acute ischemic stroke. Exclude intracranial hemorrhage as the primary cause of stroke S/S before initiation of treatment. ■ Lysis of acute massive pulmonary embolism defined as (1) acute pulmonary emboli obstructing blood flow to a lobe or to multiple lung segments, or (2) acute pulmonary emboli accompanied by unstable hemodynamics (e.g., failure to maintain BP without supportive measures).

Limitation of use:

In patients with AMI, the risk of stroke may outweigh the benefit produced by thrombolytic therapy in patients whose AMI puts them at low risk for death or heart failure.

Cathflo Activase:

Restoration of function to CVADs as assessed by the ability to withdraw blood.

Unlabeled uses:

Systemic alteplase:

Treatment of acute ischemic stroke 3 to 4.5 hours after symptom onset. Has been shown to restore blood flow to frostbitten limbs. Has been used in peripheral arterial occlusion, prosthetic valve thrombosis, and submassive pulmonary embolism.

CONTRAINDICATIONS

All indications:

Known hypersensitivity to alteplase or its components.

Acute myocardial infarction/pulmonary embolism:

Do not administer for the treatment of AMI or pulmonary embolism in the following situations in which the risk of bleeding is greater than the potential benefit: active internal bleeding, bleeding diathesis, history of recent cerebrovascular accident, recent (within 3 months) intracranial or intraspinal surgery or serious head trauma, current severe uncontrolled hypertension, presence of intracranial conditions that may increase the risk of bleeding (e.g., some neoplasms, arteriovenous malformation, or aneurysm).

Acute ischemic stroke:

Do not administer to treat acute ischemic stroke in the following situations in which the risk of bleeding is greater than the potential benefit: current intracranial hemorrhage (on pretreatment evaluation), subarachnoid hemorrhage, active internal bleeding, presence of intracranial conditions that may increase the risk of bleeding (e.g., some neoplasms, arteriovenous malformation, or aneurysm), recent (within 3 months) intracranial or intraspinal surgery or serious head trauma, bleeding diathesis, or current severe uncontrolled hypertension.

PRECAUTIONS

All systemic indications:

Administered under the direction of a physician knowledgeable in its use and with appropriate emergency drugs and diagnostic and laboratory facilities available. ■ Alteplase can cause significant, sometimes fatal, internal or external bleeding. May be internal bleeding (involving intracranial or retroperitoneal sites or the GI, GU, or respiratory tracts) or external bleeding, especially at arterial and venous puncture sites. Use extreme care with the patient; avoid IM injections and any trauma to the patient who is receiving alteplase. Avoid invasive procedures (e.g., arterial puncture and venipuncture). If these procedures are absolutely necessary, use extreme precautionary methods. To minimize bleeding from noncompressible sites, avoid internal jugular and subclavian venous punctures. If an arterial puncture is necessary, use an upper extremity vessel that is accessible to manual compression, apply pressure for at least 30 minutes, and monitor the puncture site closely. ■ Fatal cases of hemorrhage associated with traumatic intubation in patients receiving alteplase have been reported. ■ Aspirin and heparin have been administered concomitantly with and following infusions of alteplase in the management of AMI and PE. However, the administration of heparin and aspirin concomitantly with and following infusions of alteplase for the treatment of acute ischemic stroke during the first 24 hours after symptom onset has not been investigated. Because heparin, aspirin, or alteplase may cause bleeding complications, carefully monitor for bleeding. Hemorrhage can occur 1 or more days after administration of alteplase while patients are still receiving anticoagulant therapy. ■ The risk of bleeding with alteplase therapy for all systemic indications is increased and should be weighed against the anticipated benefit in any of the following conditions: recent major surgery or procedure (e.g., CABG, obstetric delivery, organ biopsy, previous puncture of noncompressible vessels), recent intracranial hemorrhage, recent GI or GU bleeding, cerebrovascular disease, hypertension (systolic above 175 mm Hg or diastolic above 110 mm Hg), recent trauma, acute pericarditis, subacute bacterial endocarditis, hemostatic defects (including those secondary to severe hepatic or renal disease), significant liver dysfunction, pregnancy, hemorrhagic ophthalmic conditions (e.g., diabetic hemorrhagic retinopathy), septic thrombophlebitis or occluded AV cannula at seriously infected site, patients taking anticoagulants, advanced age, or any situation in which bleeding might be hazardous or difficult to manage because of location. ■ Cholesterol embolism has been reported rarely and is associated with invasive procedures (e.g., cardiac catheterization, angiography, vascular surgery) and/or anticoagulant therapy; see Side Effects. ■ Hypersensitivity, including urticarial/anaphylactic reactions, have been reported. Fatalities have occurred. Angioedema has been observed during and up to 2 hours after infusion in patients treated for acute ischemic stroke and acute MI. In many cases patients received concomitant angiotensin-converting enzyme inhibitors. See Drug/Lab Interactions and Antidote.

Myocardial infarction:

Reperfusion arrhythmias can occur (e.g., sinus bradycardia, accelerated idioventricular rhythm, PVCs, ventricular tachycardia); have antiarrhythmic medications available.

Acute ischemic stroke:

Because of the higher risk of intracranial hemorrhage in patients treated for acute ischemic stroke, treatment facility must be able to provide evaluation and management of intracranial hemorrhage. ■ Risk of intracranial hemorrhage may be increased in patients with severe neurologic deficit at presentation. However, efficacy results suggest a reduced but still favorable clinical outcome for these patients. ■ Treatment may begin before coagulation study results are known in patients without recent use of oral anticoagulants or heparin. Discontinue infusion if pretreatment INR is greater than 1.7 or if an elevated aPTT is identified.

Pulmonary emboli:

Thrombolytics can increase the risk of thromboembolic events in patients with high likelihood of left heart thrombus, such as patients with mitral stenosis or atrial fibrillation. ■ Treatment with alteplase does not constitute adequate treatment of underlying deep venous thrombosis. ■ Risk of re-embolization due to lysis of underlying DVT should be considered.

Cathflo Activase:

Consider causes of catheter dysfunction other than thrombus formation (e.g., catheter malposition, mechanical failure, constriction by a suture, lipid deposits or drug precipitates within the catheter lumen). ■ Do not apply vigorous suction during attempts to determine catheter occlusion; may risk damage to the vascular wall or collapse of soft-walled catheters. ■ Avoid excessive pressure during instillation of Cathflo Activase into the catheter; may cause rupture of the catheter or expulsion of the clot into the circulation. ■ Use caution with patients who have active internal bleeding, thrombocytopenia, or other hemostatic defects (including those secondary to hepatic or renal disease). ■ Use caution in patients who have conditions for which bleeding constitutes a significant hazard, who would be difficult to manage because of location of the bleeding, who are at high risk for embolic complications (e.g., venous thrombosis in the region of the catheter), or who have had any of the following within 48 hours: surgery, obstetric delivery, percutaneous biopsy of viscera or deep tissues, or puncture of noncompressible vessels. ■ Use caution in the presence of known or suspected infection in the catheter; may release a localized infection into the systemic circulation. ■ Hypersensitivity, including urticaria, angioedema, and anaphylaxis, has been reported. ■ See Monitor. ■ Safety and effectiveness of doses greater than 2 mg have not been established.

Monitor:

All systemic indications:

Establish a separate IV line for alteplase. ■ Obtain appropriate laboratory studies (e.g., PT, TT, PTT, INR, aPTT, CBC, fibrinogen levels, platelets). ■ Diagnosis-specific baseline studies (e.g., ECG, troponin in myocardial infarction, noncontrast CT brain scan, neurologic assessment in acute ischemic stroke, and CT or pulmonary angiography in pulmonary embolism) are indicated. ■ Monitor the patient carefully and frequently for pain and signs of bleeding; observe catheter sites frequently and apply pressure dressings to any recently invaded site; watch for hematuria, hematemesis, bloody stool, petechiae, hematoma, flank pain, or muscle weakness; perform neuro checks. Continue until normal clotting function returns. ■ Monitor BP and maintain within appropriate limits with antihypertensives or vasopressors as indicated. ■ Monitor for signs of a hypersensitivity reaction (e.g., laryngeal edema, rash, shock) during and for several hours after infusion. ■ Watch for extravasation; may cause ecchymosis and/or inflammation. Restart IV at another site and apply local therapy. ■ See Precautions and Drug/Lab Interactions.

Myocardial infarction:

Monitor ECG.

Acute ischemic stroke:

Before the initiation of therapy, determine actual time of onset of stroke. ■ During and following alteplase administration, frequently monitor and control BP. The 2013 AHA/ASA guidelines for early management of acute ischemic stroke recommend (1) monitoring BP every 15 minutes for 2 hours, every 30 minutes for 6 hours, then every 1 hour for 18 hours; and (2) performing neurologic assessments every 15 minutes during infusion, every 30 minutes thereafter for the next 6 hours, and then hourly until 24 hours after treatment. ■ Hemorrhage in the brain occurs frequently during treatment with alteplase; monitor carefully. Acute neurologic deterioration, new headache, acute hypertension, or nausea and vomiting may indicate the occurrence of intracranial hemorrhage. If intracranial hemorrhage is suspected, discontinue alteplase and obtain a CT scan.

Cathflo Activase:

Aseptic technique imperative. ■ Avoid force while attempting to clear catheters; may rupture catheter or dislodge clot into the circulation. ■ Monitor for S/S of a hypersensitivity reaction. ■ See Precautions.

Patient Education:

Compliance with all measures to minimize bleeding (e.g., strict bed rest) is very important. ■ Avoid use of razors, toothbrushes, and other sharp items. Use caution while moving to avoid excessive bumping. ■ Report all S/S of bleeding (e.g., unusual bruising, pink or brown urine, red or black or tarry stools, coughing up blood, vomiting blood or blood that looks like coffee grounds, headache or stroke symptoms). Apply local pressure if indicated. Expect oozing from IV sites.

Maternal/Child:

Systemic alteplase:

Safety for use in pregnancy and breast-feeding not established. ■ Safety and effectiveness for use in pediatric patients not established.

Cathflo Activase:

Use during pregnancy only if benefits justify potential risk to the fetus. ■ Use caution during breast-feeding. ■ Has been used in patients 2 weeks to 17 years of age. Rates of serious adverse events as well as restoration of catheter function similar to adults.

Elderly:

Systemic alteplase: Possible increased risk of bleeding with advanced age (e.g., age greater than 77 years). In acute ischemic stroke, efficacy results suggest a reduced but still favorable clinical outcome for elderly patients treated with alteplase.

Cathflo Activase:

No incidents of intracranial hemorrhage, embolic events, or major bleeding events were observed during studies. ■ Use caution in the elderly with conditions known to increase the risk of bleeding; see Precautions.

DRUG/LAB INTERACTIONS

Risk of bleeding may be increased by any medicine that affects blood clotting, including **anticoagulants** (e.g., heparin, warfarin); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel, dipyridamole, glycoprotein GPIIb/IIIa receptor antagonists [e.g., eptifibatide, tirofiban]). ■ Concomitant **angiotensin-converting enzyme inhibitors** increase the risk of angioedema. ■ **Coagulation tests and measures of fibrinolytic activity** may be unreliable; specific procedures can be used; notify the lab of alteplase use.

SIDE EFFECTS

Systemic alteplase:

Bleeding is most common: internal (GI tract, GU tract, retroperitoneal, or intracranial sites) and superficial or external bleeding (ecchymosis, epistaxis, gingival bleeding, venous cutdowns, arterial punctures, sites of recent surgical intervention). Mild to serious hypersensitivity reactions (e.g., anaphylactoid reaction, laryngeal edema, orolingual angioedema, rash, urticaria) have occurred. Cholesterol embolization can occur with thrombolytics but has been reported rarely. It may present with acute renal failure, bowel infarction, cerebral infarction, gangrenous digits, hypertension, livedo reticularis, myocardial infarction, pancreatitis, purple toe syndrome, retinal artery occlusion, rhabdomyolysis, or spinal cord infarction. Fatalities have been reported.

Post-Marketing:

The following events may be life threatening:

Acute ischemic stroke (AIS):

Cerebral edema, cerebral herniation, embolism, new ischemic stroke, seizure.

Acute myocardial infarction (AMI):

Arrhythmias, AV block, cardiac arrest, cardiac tamponade, cardiogenic shock, electromechanical dissociation, fever, heart failure, hypotension, mitral regurgitation, myocardial reinfarction, myocardial rupture, nausea and/or vomiting, pericardial effusion, pericarditis, pulmonary edema, recurrent ischemia, thromboembolism.

Pulmonary embolism (PE):

Hypotension, pleural effusion, pulmonary edema, pulmonary re-embolization, thromboembolism.

Cathflo Activase:

Gastrointestinal bleeding, hypersensitivity reactions (e.g., anaphylaxis, angioedema, urticaria), sepsis, and venous thrombosis have occurred. There were no reports of intracranial hemorrhage or pulmonary emboli during clinical trials.

ANTIDOTE

Systemic alteplase:

Notify physician of all side effects. Note even the most minute bleeding tendency. Oozing at IV sites is expected. Control minor bleeding by local pressure. For severe bleeding in a critical location or suspected intracranial bleeding, discontinue alteplase and any heparin therapy immediately. Obtain PT, aPTT, platelet count, and fibrinogen. Draw blood for type and cross-match. Transfuse as indicated. Consider protamine if heparin has been used. Treat reperfusion arrhythmias with appropriate antiarrhythmic; VT or VF may require cardioversion. Treat minor hypersensitivity reactions symptomatically. If anaphylaxis or angioedema occur, discontinue infusion immediately and initiate appropriate treatment with antihistamines (e.g., diphenhydramine), IV corticosteroids, or epinephrine; resuscitate as necessary.

Cathflo Activase:

Discontinue Cathflo Activase and withdraw it from the catheter if serious bleeding in a critical location (e.g., intracranial, gastrointestinal, retroperitoneal, pericardial) occurs. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary. In the event of accidental administration of a 2-mg dose directly into the systemic circulation, the concentration of circulating levels of alteplase would be expected to return to exogenous levels of 5 to 10 ng/mL within 30 minutes.

AMIFOSTINE

(am-ih-**FOS**-teen)
Ethyol
Antidote
Chemoprotective agent
pH 7

USUAL DOSE

Pretreatment:

Verify pregnancy status. See Precautions and Monitor.

Reduction of Cisplatin-Induced Nephrotoxicity

Must be administered in conjunction with cisplatin. Adequate hydration and premedication required before administration; see Premedication below, Monitor, and cisplatin monograph.

Premedication:

Premedication to prevent severe nausea and vomiting is recommended before each dose. Usual regimen includes dexamethasone 20 mg IV and a serotonin 5-HT$_3$ receptor antagonist (e.g., ondansetron [Zofran], granisetron [Kytril]) given before the amifostine infusion. Additional antiemetics (e.g., aprepitant [EMEND]) may be required based on the chemotherapy drugs administered.

Amifostine:

910 mg/M^2 once daily as a 15-minute IV infusion starting 30 minutes before chemotherapy.

Reduction of Moderate to Severe Xerostomia from Radiation of the Head and Neck

Premedication:

Premedication to prevent nausea and vomiting is recommended before each dose. Oral 5-HT$_3$ receptor antagonists alone or in combination with other antiemetics are recommended. Adequate hydration required; see Monitor.

Amifostine:

200 mg/M^2 once daily as a 3-minute infusion, starting 15 to 30 minutes before standard fraction radiation therapy.

DOSE ADJUSTMENTS

Dosing should be cautious in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy. ■ Temporarily interrupt the infusion if the systolic BP decreases significantly from the baseline value as defined in the following chart.

Guideline for Interrupting Amifostine Infusion Due to Decrease in Systolic Blood Pressure

	Baseline Systolic Blood Pressure (mm Hg)				
	<100	100-119	120-139	140-179	≥180
Decrease in systolic blood pressure during infusion of amifostine (mm Hg)	20	25	30	40	50

Infusion may be restarted to deliver the full dose if the BP returns to normal within 5 minutes and the patient is asymptomatic. When administering amifostine at the 910 mg/M² dose, if the full dose cannot be delivered, subsequent doses should be reduced to 740 mg/M².

DILUTION

Specific techniques required; see Precautions.

Each 500-mg single-dose vial should be reconstituted with 9.7 mL of NS (50 mg/mL). Withdraw the calculated dose and further dilute with NS to deliver a final concentration between 5 and 40 mg/mL.

Filters:

Not required by manufacturer. Additional data not available.

Storage:

Store at CRT before reconstitution. Reconstituted or diluted solution prepared in PVC infusion bags is stable for 5 hours at room temperature or 24 hours if refrigerated.

COMPATIBILITY

Use of any additive, diluent, or solution other than NS is not recommended by manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Reduction of cumulative renal toxicity with chemotherapy:

A single dose evenly distributed over 15 minutes. Amifostine must be given over 15 minutes; longer infusion times increase the risk of side effects.

Reduction of moderate to severe xerostomia from radiation of the head and neck:

A single dose evenly distributed over 3 minutes.

ACTIONS

A cytoprotective agent. Rapidly metabolized by alkaline phosphatase in tissues to an active thiol metabolite that is believed to reduce the nephrotoxic effects of cisplatin and the toxic effects of radiation on normal oral tissues. This protective metabolite is generated in greater amounts in normal tissues versus tumor tissues and is available to bind to and detoxify reactive metabolites of cisplatin. This protective metabolite can also scavenge reactive oxygen species generated by exposure to either cisplatin or radiation. Rapidly cleared from plasma with an elimination half-life of 8 minutes. Minimal excretion in urine.

INDICATIONS AND USES

Reduce the cumulative renal toxicity associated with repeated administration of cisplatin in patients with advanced ovarian cancer. ■ Reduce the incidence of moderate to severe xerostomia (dryness of the mouth from salivary gland dysfunction) in patients undergoing postoperative radiation treatment for head and neck cancer, where the “radiation port” includes a substantial portion of the parotid glands.

Limitation of use:

Do not use amifostine in other settings where chemotherapy can produce a significant survival benefit or cure or in patients receiving definitive radiotherapy, except in the context of a clinical study.

Unlabeled uses:

Prevention of radiation proctitis in rectal cancer.

CONTRAINDICATIONS

Known sensitivity to aminothiol compounds. See Precautions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Not recommended for patients receiving chemotherapy for malignancies other than advanced ovarian cancer if chemotherapy can produce significant survival benefit or cure, except in the context of a clinical trial; may interfere with effectiveness of chemotherapy regimen and reduce incidence of cure. ■ Not recommended for patients receiving definitive radiotherapy, except in the context of a clinical trial. Tumor-protective effect in this setting has not been ruled out. ■ Severe hypotension and serious sequelae have been reported. Hold antihypertensive therapy during the 24 hours preceding an amifostine infusion in patients receiving doses recommended for chemotherapy (910 mg/M^2). ■ Not recommended for patients who are hypotensive or dehydrated or who are receiving amifostine at doses recommended for chemotherapy and are receiving antihypertensive therapy that cannot be stopped for 24 hours before amifostine administration. Hypotension may occur during or shortly after the amifostine infusion despite adequate hydration and positioning of the patient; see Side Effects. ■ Hypotension and nausea and vomiting can be severe. Use caution in the elderly, in patients with pre-existing cardiovascular or cerebrovascular conditions (e.g., arrhythmias, congestive heart failure, history of stroke or transient ischemic attack, history of ischemic heart disease), and in any other patients in whom these side effects may be more likely to have serious consequences. ■ Hypersensitivity reactions, including anaphylaxis and severe cutaneous reactions, have been reported; see Monitor and Side Effects. Deaths have occurred. ■ Facilities for monitoring the patient and responding to any medical emergency must be available.

Monitor:

All indications:

Adequate hydration required before administration of amifostine. ■ Monitor fluid balance carefully, especially in conjunction with highly emetogenic chemotherapy (e.g., cisplatin). ■ See Usual Dose for premedication requirements. Additional antiemetics may be required to offset nausea and vomiting of chemotherapy drugs. ■ Keep patient in supine position during and immediately after the infusion. ■ Monitor for S/S of hypersensitivity reactions (e.g., chest discomfort, chills, cutaneous eruptions, dyspnea, fever, laryngeal edema, pruritus, and urticaria); may occur during or after infusion. ■ Serious and fatal cutaneous reactions may develop weeks after initiation of therapy and occur more frequently when amifostine is used as a radioprotectant. Monitor for cutaneous reactions closely before, during, and after administration. Cutaneous reactions must be clearly differentiated from radiation-induced dermatitis and from cutaneous reactions related to an alternate etiology. ■ Monitor serum calcium. Risk of hypocalcemia increased in some patients (e.g., patients with nephrotic syndrome or patients receiving multiple doses). Calcium supplements may be required. ■ See Dose Adjustments, Rate of Administration, and Antidote.

Reduction of cumulative renal toxicity with chemotherapy:

Discontinue antihypertensive therapy if indicated; see Precautions and Drug/Lab Interactions. ■ Obtain baseline BP and monitor at least every 5 minutes during and immediately after the infusion. Continue monitoring BP as indicated. ■ Hypertension may be exacerbated by several causes (e.g., interruption of antihypertensive therapy, IV hydration). Monitor BP closely. ■ Hypotension can occur at any time but is more frequent toward the end of the infusion, and recovery usually begins within 5 to 15 minutes after infusion is discontinued.

Reduction of xerostomia from radiation:

Monitor BP before and immediately after the infusion and as indicated by results.

Patient Education:

Void before administration. ■ May produce significant hypotension. Effects may be additive with medications currently being taken. Review all medications (prescription and nonprescription) with nurse and/or physician. ■ Must remain in supine position until BP is stabilized, then request assistance for ambulation. ■ Promptly report S/S of hypersensitivity reaction, feelings of faintness, or nausea. ■ Promptly report development of any rash or skin condition. ■ Effective contraception required; see monographs for the chemotherapy products used for each indication. ■ May impair fertility in males of reproductive potential.

Maternal/Child:

Based on animal studies, amifostine can cause fetal harm when administered to a pregnant woman. Use only if potential benefits justify risk to fetus. ■ Discontinue breast-feeding. ■ Not recommended for use in pediatric patients; safety and effectiveness not established.

Elderly:

Response similar to younger adults; however, dosing should be cautious; see Dose

Adjustments. ■ Monitor fluid balance closely; avoid dehydration. ■ Hypotension may be sudden and severe; monitor closely. ■ See Precautions.

DRUG/LAB INTERACTIONS

Antihypertensive therapy (**e.g., ACE inhibitors** [e.g., enalapril], **calcium channel blocking agents** [e.g., nicardipine, verapamil], **diuretics** [e.g., furosemide, torsemide], **nitroglycerin**) should be discontinued 24 hours before amifostine administration; see Precautions. ■ Use caution in any patient receiving medications with **hypotensive effects** (**antidepressants, benzodiazepines, beta-adrenergic blocking agents** [e.g., atenolol, esmolol, metoprolol, propranolol], **lidocaine, magnesium, narcotics, nitrates, paclitaxel, procainamide**); will cause additive hypotension.

SIDE EFFECTS

Hypotension and severe nausea and vomiting occur frequently. Hypotension may be associated with apnea, arrhythmias (e.g., atrial fibrillation/flutter, bradycardia, extrasystoles, supraventricular tachycardia, tachycardia), chest pain, dyspnea, hypoxia, myocardial ischemia or infarction and, rarely, renal failure, respiratory and cardiac arrest, seizures, and unconsciousness. Chills, dehydration, diarrhea, diplopia and blurred vision, dizziness, feelings of cold or warmth, fever, flushing, hiccups, hypocalcemia, injection site reactions (e.g., bruising, erythema, inflammation, local swelling, pain, pruritus, rash, urticaria), loss of consciousness, malaise, sneezing, somnolence, and/or transient hypertension or exacerbation of pre-existing hypertension may occur. Hypersensitivity reactions (e.g., anaphylaxis [rare], arrhythmias, chest tightness, chills, cutaneous eruptions, dyspnea, fever, hypotension, hypoxia, laryngeal edema, pruritus, urticaria) have occurred. Most cutaneous eruptions, pruritus, rigors, and urticaria were mild; however, serious skin reactions such as drug reaction with biopsy-confirmed eosinophilia and systemic symptoms (DRESS), erythema multiforme, exfoliative dermatitis, rash, Stevens-Johnson syndrome (rare), toxic epidermal necrolysis, toxicoderma, and urticaria have been reported. Serious skin reactions have been reported more frequently when amifostine is used as a radioprotectant.

Overdose:

Hypotension is the most likely symptom. Anxiety and reversible urinary retention have occurred at higher doses. Up to 3 doses have been given within 24 hours without unexpected side effects.

ANTIDOTE

Keep physician informed of side effects. Treatment of nausea and vomiting is imperative to encourage patients to continue treatment with full doses of chemotherapeutic agents. Hypotension may be dose-limiting. If the systolic BP decreases significantly (see Dose Adjustments chart), temporarily discontinue the amifostine still infusing, place the patient in Trendelenburg position, and administer an infusion of NS at a separate site. If indicated, restart infusion if BP returns to baseline within 5 minutes and patient is asymptomatic. Discontinue amifostine immediately and permanently if a serious acute hypersensitivity or cutaneous reaction occurs. Dermatologic consult may be required. Treat hypersensitivity reactions as indicated and resuscitate as necessary.

AMIKACIN SULFATE BBW

(am-ih-**KAY**-sin **SUL**-fayt)
Antibacterial (aminoglycoside)
pH 3.5 to 5.5

USUAL DOSE

Up to 15 mg/kg of body weight/24 hr equally divided into 2 or 3 doses at equally divided intervals (5 mg/kg every 8 hours or 7.5 mg/kg every 12 hours). Dosage based on ideal weight of lean body mass.

Studies suggest that in certain populations a single daily dose of 15 to 20 mg/kg (instead of divided into 2 or 3 doses) may provide higher peak levels and enhance drug effectiveness while actually reducing or having no adverse effects on risk of toxicity. Various procedures for monitoring blood levels are in use. Some health facilities are monitoring with trough levels; others may draw levels at predetermined times and plot the concentration on nomograms. Depending on the protocol in place, doses or intervals may be adjusted. See Dose Adjustments and Precautions.

PEDIATRIC DOSE

15 to 22.5 mg/kg/24 hr equally divided into 2 or 3 doses and given every 8 to 12 hours (5 to 7.5 mg/kg every 8 hours or 7.5 to 11.25 mg/kg every 12 hours). Do not exceed 1.5 Gm/24 hr. A single daily dose is also being used in pediatric patients. See comments under Usual Dose.

NEWBORN DOSE

See Maternal/Child.

10 mg/kg of body weight as a loading dose, then 7.5 mg/kg/dose. Intervals of 7.5 mg/kg dose adjusted based on age as follows:

Under 28 weeks' gestation and under 7 days of age:

Give every 24 hours.

Under 28 weeks' gestation and over 7 days or 28 to 34 weeks' gestation and under 7 days of age:

Give every 18 hours.

28 to 34 weeks' gestation and over 7 days of age or over 34 weeks' gestation and under 7 days of age:

Give every 12 hours.

Over 34 weeks' gestation and over 7 days of age:

Give every 8 hours.

DOSE ADJUSTMENTS

Reduce daily dose commensurate with amount of renal impairment and/or increase intervals between injections. ■ Once-daily dosing is not usually used in patients with ascites, burns covering more than 20% of the total body surface area, CrCl less than 40 mL/min (including patients requiring dialysis), CrCl greater than 120 mL/min, cystic fibrosis, endocarditis, mycobacterium infections, or in infants or pregnancy. ■ Reduced dose or extended intervals may be required in the elderly. ■ See Drug/Lab Interactions.

DILUTION

Each 500 mg or fraction thereof is diluted with 100 to 200 mL D5W, D5NS, or NS. Amount of diluent may be decreased proportionately with dosage for infants and other pediatric patients. Available for pediatric injection as 50 mg/mL.

Storage:

Stable for 24 hours at RT at concentrations of 0.25 and 5 mg/mL when diluted in specific solutions; see prescribing information.

COMPATIBILITY

Do not physically premix with other drugs; administer separately as recommended by manufacturer. Inactivated in solution with beta-lactam antibiotics (e.g., cephalosporins, penicillins) and vancomycin. Do not mix in the same solution. Appropriate spacing required because of physical **incompatibilities**. See Drug/Lab Interactions.

Solution:

Manufacturer lists D5W, D5/¼NS, D5/$^{1}/_{2}$NS, NS, LR, D5 in Normosol M (Plasma-Lyte 56 in D5W), D5 in Normosol R (Plasma-Lyte 148 in D5W).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over at least 30 to 60 minutes. Infants should receive a 1- to 2-hour infusion.

ACTIONS

An aminoglycoside antibiotic with neuromuscular blocking action. Bactericidal against many gram-negative organisms resistant to other antibiotics including other aminoglycosides such as gentamicin, kanamycin, and tobramycin. Well distributed through all body fluids. Usual half-life is 2 to 3 hours. Crosses the placental barrier. Excreted in the kidneys. Cross-allergenicity does occur between aminoglycosides.

INDICATIONS AND USES

Short-term treatment of serious infections caused by susceptible organisms (e.g., gram-negative bacteria) generally resistant to alternate drugs that have less potential toxicity. ■ Effective in infections of the respiratory and urinary tracts, CNS (including meningitis), skin and soft tissue, intra-abdominal (including peritonitis), bacterial septicemia (including neonatal sepsis), burns, and postoperative infections. ■ Considered initial therapy in suspected gram-negative infections after culture and sensitivity is drawn. ■ In certain severe infections (e.g., neonatal sepsis), empiric concomitant treatment with an antibiotic effective against gram-positive organisms (e.g., penicillin) may be required until the results of C/S are obtained.

Unlabeled uses:

Treatment of *Mycobacterium avium* complex, a common infection in AIDS (part of a multiple [3 to 5] drug regimen), tuberculosis.

CONTRAINDICATIONS

Known amikacin or aminoglycoside sensitivity. Sulfite sensitivity may be a contraindication.

PRECAUTIONS

Sensitivity studies indicated to determine susceptibility of causative organism to amikacin. ■ Response should occur in 24 to 48 hours. Safety for use longer than 14 days not established. ■ Superinfection may occur from overgrowth of nonsusceptible organisms. ■ May contain sulfites; use caution in patients with asthma. ■ Single daily dosing has been used effectively in abdominal, pelvic inflammatory, and GU infections in patients with normal renal function. Not recommended in bacteremia caused by *Pseudomonas aeruginosa,* endocarditis, meningitis, during pregnancy, or in patients less than 6 weeks postpartum. Limited data available for use in all other situations (e.g., burns, cystic fibrosis, elderly, pediatrics, renal impairment). ■ Potentially nephrotoxic, ototoxic, and neurotoxic. Risk of nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity) increased in patients with pre-existing renal damage or in normal renal function with prolonged use. Partial or total irreversible deafness may continue to develop after amikacin is discontinued. ■ Use with caution in patients with muscular disorders (e.g., myasthenia gravis, parkinsonism) because these drugs may aggravate muscle weakness. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with amikacin. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Maintain good hydration. ■ Narrow range between toxic and therapeutic levels. Periodically monitor peak and trough concentrations. Manufacturer recommends avoiding peak serum concentrations greater than 35 mcg/mL and trough serum concentrations above 10 mcg/mL. ■ Monitor urine protein, presence of cells and casts, and decreased specific gravity. Watch for decreased urine output, rising BUN and SCr, and declining CrCl levels. Dose adjustment may be necessary. ■ Closely monitor patients with impaired renal function for nephrotoxicity and neurotoxicity (e.g., auditory and vestibular ototoxicity); nephrotoxicity may be reversible. ■ In extended treatment, monitor serum levels, electrolytes, and renal, auditory, and vestibular functions frequently. ■ See Drug/Lab Interactions.

Patient Education:

Report promptly any changes in balance, hearing loss, weakness, or dizziness. ■ Consider birth control options. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category D: avoid pregnancy. Potential hazard to fetus. ■ Safety for use during breast-feeding not established; use extreme caution. ■ Peak concentrations are generally lower in infants and young children. ■ Use extreme caution in premature infants and neonates; immature kidney function will result in prolonged half-life.

Elderly:

Consider less toxic alternatives. ■ Longer intervals between doses may be more important than smaller doses. ■ Monitor renal function and drug levels carefully. Measurement of CrCl more useful than BUN or SCr to assess renal function. ■ Half-life prolonged.

DRUG/LAB INTERACTIONS

Synergistic when used in combination with **beta-lactam antibiotics** (e.g., cephalosporins, penicillins) **and vancomycin.** Synergism may be inconsistent; see Compatibility. ■ Concurrent use topically or systemically with any other **ototoxic or nephrotoxic agents** should be avoided. May have dangerous additive effects with **anesthetics, other neuromuscular blocking antibiotics, diuretics, beta-lactam antibiotics** (e.g., cephalosporins), **vancomycin, and many others.** ■ **Neuromuscular blocking muscle relaxants** (e.g., atracurium, succinylcholine) are potentiated by aminoglycosides. *Apnea can occur.* ■ Aminoglycosides are potentiated by anticholinesterases and **antineoplastics.**

SIDE EFFECTS

Occur more frequently with impaired renal function, higher doses, prolonged administration, in dehydrated or elderly patients, and in patients receiving other ototoxic or nephrotoxic drugs. Fever, headache, hypotension, nausea, paresthesias, seizures, skin rash, tremor, vomiting.

Major:

Albuminuria, anemia, arthralgia, azotemia, CDAD, eosinophilia, loss of balance, neuromuscular blockade, oliguria, ototoxicity, RBCs and WBCs or casts in urine, respiratory depression or arrest, rising SCr.

ANTIDOTE

Notify physician of all side effects. If minor side effects persist or any major symptom appears, discontinue drug and notify physician. Treatment is symptomatic, or a reduction in dose may be required. In overdose hemodialysis may be indicated. Monitor fluid balance, CrCl, and plasma levels carefully. Complexation with ticarcillin may be as effective as hemodialysis. Consider exchange transfusion in the newborn. Calcium salts or neostigmine may reverse neuromuscular blockade. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

AMINOCAPROIC ACID

(a-mee-noh-ka-**PROH**-ick **AS**-id)
Amicar
Antifibrinolytic
Antihemorrhagic
pH 6 to 7.6

USUAL DOSE

Pretreatment:

Pretesting and baseline studies required; see Precautions and Monitor.

4 to 5 Gm initially over 1 hour. Follow with 1 Gm/hr for 8 hours or until bleeding is controlled. In acute bleeding syndromes, the 4- to 5-Gm dose may be given as a continuous infusion over the first hour, followed by a continuous infusion of 1 Gm/hr for 8 hours or until bleeding is controlled. Maximum dose is 30 Gm/24 hr.

Prevent recurrence of subarachnoid hemorrhage (unlabeled):

36 Gm/24 hr. One source suggests administering 18 Gm in 400 mL D5W every 12 hours for 10 days. Follow with oral therapy.

Prevention of perioperative bleeding during cardiac surgery (unlabeled):

10 Gm as an infusion over 20 to 30 minutes before skin incision. Follow with 1 to 2.5 Gm/hr (usually 2 Gm/hr) until the end of the operation. Infusion may be continued for 4 hours after protamine reversal of heparin. In addition, 10 Gm may be added to the cardiopulmonary bypass circuit priming solution. An alternate regimen is 10 Gm over 20 to 30 minutes before skin incision, followed by 10 Gm after heparin administration, then 10 Gm when cardiopulmonary bypass is discontinued and before protamine reversal of heparin. Another source suggests a loading dose of 80 mg/kg over 20 minutes followed by 30 mg/kg/hr, or a loading dose of 60 mg/kg over 20 minutes followed by 30 mg/kg/hr plus a 10-mg/kg dose in the priming solution of the cardiopulmonary bypass pump.

PEDIATRIC DOSE

Acute bleeding syndromes (unlabeled):

See Maternal/Child. ***Loading dose:*** 100 to 200 mg/kg. Follow with a maintenance dose of 100 mg/kg/dose every 4 to 6 hours. Maximum dose is 30 Gm/24 hr.

DOSE ADJUSTMENTS

May accumulate in patients with renal impairment, and reduced doses are suggested; however, specific recommendations are not available from the manufacturer. Another source suggests decreasing dose to 15% to 25% of the normal dose in patients with renal impairment.

DILUTION

1 Gm equals 4 mL of prepared solution. Further dilute with **compatible** infusion solutions (NS, D5W, SWFI, or Ringer’s solution). Up to 50 mL of diluent may be used for each 1 Gm.

Storage:

Before use store at CRT. Do not freeze.

COMPATIBILITY

Compatible in D5W, Ringer’s solution, and NS.

RATE OF ADMINISTRATION

5 Gm or fraction thereof over first hour in 250 mL of solution; then administer each succeeding 1 Gm over 1 hour in 50 to 100 mL of solution. Use of an infusion pump for accurate dose recommended. Rapid administration or insufficient dilution may cause

hypotension, bradycardia, and/or arrhythmia.

ACTIONS

A 6-aminohexanoic acid that acts as an inhibitor of fibrinolysis. Inhibits plasminogen activator substances; to a lesser degree inhibits plasmin activity. Increases fibrinogen activity in clot formation by inhibiting the enzyme required for destruction of formed fibrin. Onset of action is prompt, but will last less than 3 hours. Partially metabolized. Half-life is 2 hours. Excreted in urine. Easily penetrates RBCs and tissue cells after prolonged administration.

INDICATIONS AND USES

Useful in enhancing hemostasis when fibrinolysis contributes to bleeding. ■ Treatment of fibrinolytic bleeding, which may be associated with surgical complications following heart surgery (with or without cardiac bypass procedures) and portacaval shunt, hematologic disorders such as aplastic anemia, acute and life-threatening abruptio placentae, hepatic cirrhosis, and neoplastic disease such as carcinoma of the prostate, lung, stomach, and cervix. ■ Urinary fibrinolysis (normal physiologic phenomenon), which may result from severe trauma, anoxia, shock, surgical hematuria complications following prostatectomy and nephrectomy, or nonsurgical hematuria resulting from polycystic or neoplastic disease of the GU system.

Unlabeled uses:

Prevent recurrence of subarachnoid hemorrhage. ■ Control of bleeding in thrombocytopenia. ■ Prevention of perioperative bleeding during cardiac surgery. ■ Prophylaxis and treatment during dental surgical procedures (hemophilia and/or hemorrhage).

CONTRAINDICATIONS

Evidence of an active intravascular clotting process. ■ Uncertainty as to whether the cause of bleeding is primary fibrinolysis (PF) or disseminated intravascular coagulation (DIC). This distinction must be made before administration; see Precautions. ■ Do not use aminocaproic acid in the presence of DIC without concomitant heparin.

PRECAUTIONS

Should not be administered without a definite diagnosis and/or lab findings indicative of hyperfibrinolysis. ■ The following tests are used to differentiate primary fibrinolysis (PF) from disseminated intravascular coagulation (DIC). Platelet count should be normal in PF but is usually decreased in DIC; protamine paracoagulation test is negative in PF and positive in DIC (a precipitate forms when protamine sulfate is dropped into citrated plasma); euglobulin clot lysis test is abnormal in PF but normal in DIC. ■ In life-threatening situations, transfusion and other appropriate emergency measures may be required. ■ Avoid use in patients with hematuria of upper urinary tract origin. Has caused glomerular capillary thrombosis in the renal pelvis and ureters, leading to intrarenal obstruction. ■ Use with caution in patients with cardiac disease. May cause hypotension and bradycardia. Endocardial hemorrhage and fatty degeneration of the myocardium have been reported in animals. ■ Use with caution in patients with hepatic disease. Etiology of bleeding may be multifactorial and difficult to diagnose. ■ Use with caution in patients with renal impairment; see Dose Adjustments. Kidney stones have been reported in animal studies. ■ Skeletal muscle weakness with necrosis of muscle fibers has been reported after prolonged use; see Monitor. ■ An increased incidence of certain neurologic deficits (e.g., cerebral ischemia, cerebral vasospasm, hydrocephalus) associated with the use of antifibrinolytic agents in the treatment of subarachnoid hemorrhage has been reported. Relationship to drug therapy versus natural disease process or diagnostic procedures (e.g., angiography) is unclear.

Monitor:

See Precautions and Contraindications. ■ Use only in conjunction with general and specific tests to determine the amount of fibrinolysis present (e.g., fibrinogen, PT, aPTT). ■ Monitor lab evaluations as appropriate for diagnosis (e.g., platelet count, clotting factors, CPK, AST). ■ Vital signs, intake and output, any signs of bleeding, and neurologic assessment should be monitored based on patient condition. ■ Observe for thromboembolic complications (e.g., chest pain, dyspnea, edema, hemoptysis, leg pain, or positive Homans' sign). ■ Monitor for S/S of skeletal muscle damage. May range from mild myalgias with weakness to severe proximal myopathy with rhabdomyolysis, myoglobinuria, and acute renal failure. ■ Monitor lab evaluations as appropriate for diagnosis (e.g., platelet count, clotting factors, CPK, AST).

Patient Education:

Move slowly with help to avoid orthostatic hypotension.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established. ■ Safety for use in pediatric patients not established but is used. ■ Contains benzyl alcohol, which has been associated with "gasping syndrome" in neonates (sudden onset of gasping respirations, hypotension, bradycardia, and cardiovascular collapse).

Elderly:

Consider age-related impaired organ function; reduced dose may be indicated.

DRUG/LAB INTERACTIONS

Potential for thrombus formation increased with concurrent use of **estrogens.** ■ Frequently used with **clotting factor complexes** (e.g., factor IX complex, anti-inhibitor coagulant complex), but risk of thrombus formation may be increased. Delay administration for 8 or more hours after clotting factor complexes. ■ Prolongation of template **bleeding time** has been reported during continuous infusions exceeding 24 Gm/day.

SIDE EFFECTS

Generally well tolerated. Abdominal pain, agranulocytosis, bradycardia, coagulation disorder, confusion, cramps, decreased vision, diarrhea, dizziness, dyspnea, edema, grand mal seizure, hallucinations, headache, hypersensitivity reactions (including anaphylaxis), hypotension, increased BUN and CPK, injection site reactions, intracranial hypertension, leukopenia, malaise, muscle weakness, myalgia, myopathy, myositis, nausea, peripheral ischemia, pruritus, pulmonary embolism, renal failure, rhabdomyolysis, rash, stuffy nose, stroke, syncope, tearing, thrombocytopenia, thrombophlebitis, thrombosis, tinnitus, vomiting.

Overdose:

Acute renal failure, convulsions, death.

ANTIDOTE

Treat side effects symptomatically. Discontinue use of drug with any suspicion of thrombophlebitis, thromboembolic complications, or if CPK is elevated (myopathy). In life-threatening situations, fresh whole blood transfusions, fibrinogen infusions, and other emergency measures may be required. May be removed by hemodialysis or peritoneal dialysis.

AMINOPHYLLINE

(am-ih-**NOFF**-ih-lin)
Bronchodilator
Respiratory stimulant
pH 8.6 to 9

USUAL DOSE

To obtain maximum benefit with minimal risk of adverse effects, dosing must be individualized based on serum theophylline concentration and patient response. Monitor frequently to avoid toxicity. Only aminophylline premixed in solution or aminophylline containing 20 mg of theophylline for each 25 mg of aminophylline is intended for IV use (approximately 79% theophylline). ***All doses are based on lean body weight;*** theophylline does not distribute into fatty tissue. ***All doses listed are milligrams of aminophylline to be administered.***

Bronchodilation in Acute Asthma or Bronchospasm

With an average mean volume of distribution of 0.5 L/kg (range is 0.3 to 0.7 L/kg), each mg/kg of theophylline given over 30 minutes should result in an average 2 mcg/mL increase in serum theophylline concentration.

Adults, children, infants, and neonates who *have not* received a theophylline preparation in the previous 24 hours:

An ***initial loading dose*** of 5 to 6 mg/kg of lean body weight (5.7 mg of aminophylline is equal to 4.6 mg/kg of theophylline) should produce a serum concentration of 10 mcg/mL (range 6 to 16 mcg/mL). Measure serum theophylline concentration in 30 minutes to determine if additional loading doses are indicated. Once a serum concentration of 10 to 15 mcg/mL is obtained with loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See Dose Adjustments and Monitor for recommendations of serum theophylline testing after an infusion is started.

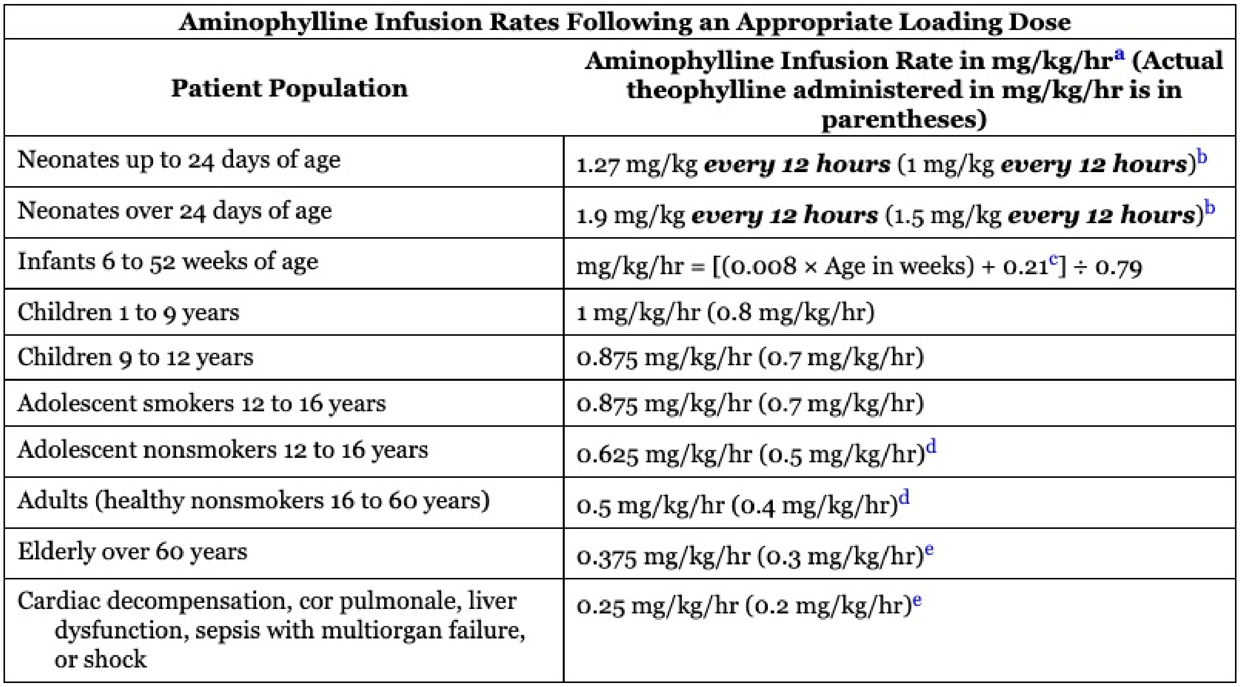
Adults, children, infants, and neonates who *have* received a theophylline preparation in the previous 24 hours:

A serum theophylline concentration must be obtained before considering any loading dose. For pediatric patients not receiving aminophylline or theophylline, give a loading dose of 5 to 7 mg/kg/dose. Maintenance dose is dependent on age. See the following chart for maintenance doses.

Once a serum concentration of 10 to 15 mcg/mL is obtained with or without loading dose(s), it should be maintained with a continuous infusion. Rate of infusion is based on the pharmacokinetic parameters (e.g., volume of distribution, clearance, concomitant disease states) of the specific patient population and should achieve a target serum concentration of 10 mcg/mL. See Dose Adjustments and Monitor for recommendations of serum theophylline testing after an infusion is started.

Maintenance infusion:

Desired theophylline serum concentration is 10 mcg/mL. Most maintenance doses can be reduced within the first 12 hours based on serum theophylline levels and depending on patient condition and response; see Dose Adjustments. Because of a large interpatient variability in theophylline clearance, each patient may differ from the mean value used to calculate these infusion rates. Another serum concentration is recommended one expected half-life after starting the continuous infusion; see Dose Adjustments.



Aminophylline Infusion Rates Following an Appropriate Loading Dose	
Patient Population	**Aminophylline Infusion Rate in mg/kg/hr[a] (Actual theophylline administered in mg/kg/hr is in parentheses)**
Neonates up to 24 days of age	1.27 mg/kg ***every 12 hours*** (1 mg/kg ***every 12 hours***)[b]
Neonates over 24 days of age	1.9 mg/kg ***every 12 hours*** (1.5 mg/kg ***every 12 hours***)[b]
Infants 6 to 52 weeks of age	mg/kg/hr = [(0.008 × Age in weeks) + 0.21[c]] ÷ 0.79
Children 1 to 9 years	1 mg/kg/hr (0.8 mg/kg/hr)
Children 9 to 12 years	0.875 mg/kg/hr (0.7 mg/kg/hr)
Adolescent smokers 12 to 16 years	0.875 mg/kg/hr (0.7 mg/kg/hr)
Adolescent nonsmokers 12 to 16 years	0.625 mg/kg/hr (0.5 mg/kg/hr)[d]
Adults (healthy nonsmokers 16 to 60 years)	0.5 mg/kg/hr (0.4 mg/kg/hr)[d]
Elderly over 60 years	0.375 mg/kg/hr (0.3 mg/kg/hr)[e]
Cardiac decompensation, cor pulmonale, liver dysfunction, sepsis with multiorgan failure, or shock	0.25 mg/kg/hr (0.2 mg/kg/hr)[e]

[a] Lower initial dose may be required for patients receiving other drugs that decrease theophylline clearance (e.g., cimetidine [Tagamet]).

[b] To achieve a target concentration of 7.5 mcg/mL for neonatal apnea.

[c] The 0.21 factor was not adjusted from the theophylline formula because it may not have the same proportional value. See package insert or contact Abbott if additional information desired.

[d] Not to exceed 900 mg/day unless serum levels indicate need for a larger dose.

[e] Not to exceed 400 mg/day or 21 mg/hr (17 mg/hr as theophylline) unless serum levels indicate need for a larger dose.

Reverse Adenosine-Mediated Effects of Dipyridamole in Adults (Unlabeled)

50 to 100 mg over 30 to 60 seconds. Do not exceed a rate of 50 mg/30 sec. Maximum dose is 250 mg.

NEONATAL DOSE

Apnea and bradycardia of prematurity (unlabeled):

Loading dose:

5 to 6 mg/kg given over 20 to 30 minutes. See all criteria under Usual Dose.

Maintenance dose:

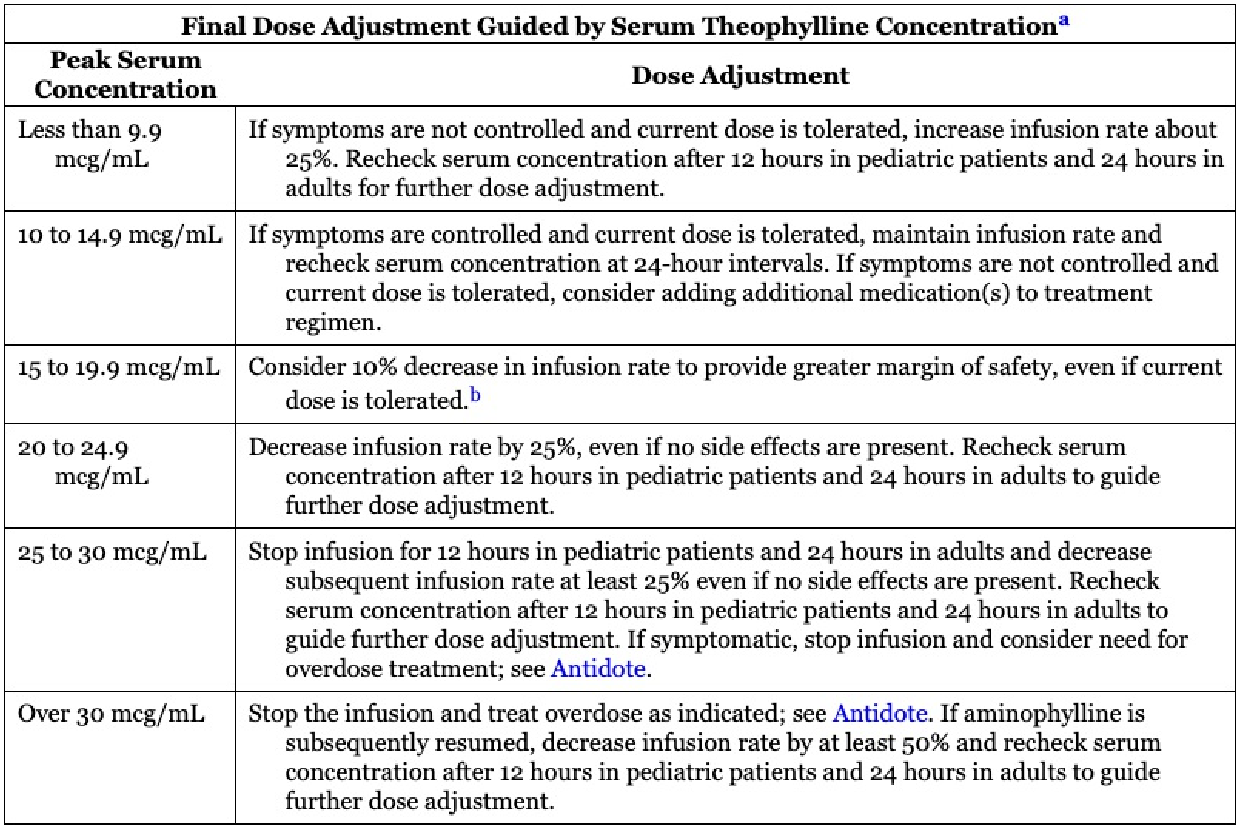
See Maintenance Infusion under Usual Dose. Manufacturer recommends keeping serum theophylline level at 7.5 mcg/mL. Another source recommends 1 to 2 mg/kg/dose every

6 to 8 hours.

DOSE ADJUSTMENTS

To determine if the concentration is accumulating or declining from the post–loading dose level, a serum concentration is recommended one expected half-life after starting the continuous infusion; see the following chart or see literature for a complete summary. If the level is declining (higher than average clearance), consider an additional loading dose or increasing the infusion rate. If the level is increasing, assume accumulation and decrease the infusion rate before the level exceeds 20 mcg/mL.

There are huge variances in patients with concurrent illness or altered physiologic states (e.g., acute pulmonary edema, COPD, cystic fibrosis, fever with acute viral respiratory illness in pediatric patients [9 to 15 years], liver disease, pregnancy, sepsis with multiorgan failure, thyroid disease); see package insert. ■ In patients with cor pulmonale, cardiac decompensation, liver dysfunction, or in those taking drugs that markedly reduce theophylline clearance (e.g., cimetidine), the initial aminophylline infusion rate should not exceed 21 mg/hr (17 mg/hr as theophylline) unless serum concentrations can be monitored every 24 hours. Up to 5 days may be required before steady state is reached in these patients; see Drug Interactions. ■ To decrease the risk of side effects associated with unexpected large increases in serum theophylline concentration, dose adjustment recommendations should be considered as the upper limit.



Final Dose Adjustment Guided by Serum Theophylline Concentration[a]

Peak Serum Concentration	Dose Adjustment
Less than 9.9 mcg/mL	If symptoms are not controlled and current dose is tolerated, increase infusion rate about 25%. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults for further dose adjustment.
10 to 14.9 mcg/mL	If symptoms are controlled and current dose is tolerated, maintain infusion rate and recheck serum concentration at 24-hour intervals. If symptoms are not controlled and current dose is tolerated, consider adding additional medication(s) to treatment regimen.
15 to 19.9 mcg/mL	Consider 10% decrease in infusion rate to provide greater margin of safety, even if current dose is tolerated.[b]
20 to 24.9 mcg/mL	Decrease infusion rate by 25%, even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.
25 to 30 mcg/mL	Stop infusion for 12 hours in pediatric patients and 24 hours in adults and decrease subsequent infusion rate at least 25% even if no side effects are present. Recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment. If symptomatic, stop infusion and consider need for overdose treatment; see Antidote.
Over 30 mcg/mL	Stop the infusion and treat overdose as indicated; see Antidote. If aminophylline is subsequently resumed, decrease infusion rate by at least 50% and recheck serum concentration after 12 hours in pediatric patients and 24 hours in adults to guide further dose adjustment.

[a] Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL.

[b] Dose reduction and/or serum theophylline concentration measurement is indicated whenever side effects are present, physiologic abnormalities that can reduce theophylline clearance occur (e.g., sustained fever), or a drug that interacts with theophylline is added or discontinued; see Precautions and Drug/Lab Interactions.

DILUTION

Check vial carefully; must state, "For IV use." Warm to room temperature. Only the 25 mg/mL solution may be given by IV injection undiluted, but further dilution for infusion in at least 100 to 200 mL of D5W is preferred. NS or dextrose in saline solutions may be used. Available prediluted. Crystals will form if solution pH falls below 8.

Storage:

Usually stored between 15° and 30° C (59° and 86° F). Protect from light and freezing.

COMPATIBILITY

Manufacturer states, "Should not be mixed in a syringe with other drugs but should be added separately to the IV solution," and recommends discontinuing other solutions infusing at the same site if there is a potential problem with admixture **incompatibility.** Manufacturer recommends avoiding admixtures with alkali labile drugs (e.g., epinephrine, norepinephrine, isoproterenol, penicillin G potassium). Precipitation in acidic media may occur with the undiluted solution but not to dilute solutions in IV infusions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over a minimum of 20 to 30 minutes. Most references suggest a minimum of 30 minutes. Do not exceed an average rate of 1 mL or 25 mg/min when giving by IV injection or as an infusion. Rapid administration may cause cardiac arrhythmias. Discontinue primary infusion if theophylline administered by piggyback or additive tubing and a possible **incompatibility** problem exists.

Reverse adenosine-mediated effects of dipyridamole:

See Usual Dose.

ACTIONS

An alkaloid xanthine derivative. It relaxes smooth muscle in the airways (bronchodilation) and suppresses the response of the airways to stimuli (nonbronchodilator prophylactic effects). Cardiac output, urinary output, and sodium excretion are increased. Skeletal and cardiac muscles are stimulated, as is the CNS to a lesser degree. There is peripheral vasodilation. It decreases pulmonary artery pressure and lowers the threshold of the respiratory center to CO_2. Well distributed throughout the body. In adults and pediatric patients over 1 year of age, 90% of a dose is metabolized in the liver. Because of a large interpatient variability in theophylline clearance, half-life varies extensively based on age, concurrent illness, or altered physiologic state; see Dose Adjustments, Precautions, Maternal/Child, and Elderly. Excreted in a changed form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunct to inhaled beta-2 selective agonists (e.g., albuterol) and systemic corticosteroids for the treatment of acute exacerbations of the symptoms and reversible airflow obstruction associated with asthma and other chronic lung diseases (e.g., emphysema, chronic bronchitis).

Unlabeled uses:

Apnea and bradycardia of prematurity. ■ Reduce bronchospasm in cystic fibrosis and acute descending respiratory infections. ■ Relieve periodic apnea and increase arterial blood pH in patients with Cheyne-Stokes respirations. ■ Reverse adenosine-mediated effects of dipyridamole- (Persantine), adenosine- (Adenoscan), or regadenoson- (Lexiscan) induced adverse reactions (e.g., angina pectoris, bronchospasm, severe hypotension, ventricular arrhythmias).

CONTRAINDICATIONS

Known hypersensitivity to theophylline or ethylenediamine.

PRECAUTIONS

Theophylline clearance may be reduced in neonates (term and premature); children less than 1 year; elderly (over 60 years); infants less than 3 months of age with reduced renal function; patients with acute pulmonary edema, congestive heart failure, cor pulmonale, hypothyroidism, liver disease (e.g., cirrhosis, acute hepatitis), sepsis with multiorgan failure, shock; or in patients with a fever of 102° F or more for 24 hours or more, or lesser temperature elevations for longer periods. Risk of severe toxicity increased in these patient populations; dose reduction and more frequent monitoring may be required. ■ Use with extreme caution in patients with active peptic ulcer disease, cardiac arrhythmias (not including bradyarrhythmias), or seizures; may exacerbate these conditions. ■ Initiate oral therapy as soon as symptoms are adequately improved. ■ See Maternal/Child and Drug/Lab Interactions.

Monitor:

Monitor serum levels as directed in Usual Dose and Dose Adjustments to achieve maximum benefit with minimum risk. Each 0.5 mg/kg will increase serum theophylline by 1 mcg/mL. 10 mcg/mL to less than 20 mcg/mL is considered therapeutic. Peak serum level is best measured 20 to 30 minutes after initial loading dose, a half-life after the initial infusion, or 12 to 14 hours into continuous infusion. ■ Monitor vital signs, including lung sounds. ■ Monitor for all signs of toxicity; see Side Effects. Serious toxicity may not be preceded by less severe side effects. ■ Serum theophylline measurements are indicated before making a dose increase; whenever signs or symptoms of toxicity are present; whenever a new illness presents, an existing illness worsens, or a change in treatment regimen is initiated that may alter theophylline clearance (e.g., sustained fever, hepatitis [see Precautions], or drugs that may interact [see Drug/Lab Interactions]); and every 24 hours throughout the infusion. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on aminophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ Dose increases should not be made in patients with an acute exacerbation of symptoms unless the steady-state serum theophylline concentration is less than 10 mcg/mL. ■ Patients with a very high initial clearance rate (low steady-state serum theophylline concentrations at above-average doses) are likely to experience large changes in serum concentration in response to dose changes. ■ Maintain hydration. ■ See Precautions, Maternal/Child, Elderly, and Drug/Lab Interactions.

Patient Education:

Do not take or discontinue any prescription or over-the-counter medication, including herbal products, without physician's approval. ■ Promptly report S/S of toxicity (e.g., nausea and vomiting).

Maternal/Child:

Category C: use in pregnancy only if clearly indicated. ■ Neonates may have therapeutic blood levels and may develop apnea from theophylline withdrawal. ■ Elimination of drug is prolonged in premature infants, neonates, and children up to 1 year. Use with extreme caution in pediatric patients. Has caused fatal reactions. Elimination reaches maximum values by 1 year of age, remains fairly constant to 9 years of age, and slowly decreases by approximately 50% to adult values at 16 years of age. ■ Pediatric patients under the age of 1 year, as well as neonates with decreased renal function, require careful attention to dosing and frequent monitoring of serum theophylline concentrations. ■ Secreted in breast milk; some sources recommend discontinuing breast-feeding. If the decision is made to breast-feed, monitor infant for evidence of side effects.

Elderly:

Compared to healthy young adults, clearance of theophylline is decreased an average of 30% in healthy elderly. Monitor dosing carefully; frequent serum theophylline concentrations are recommended. See Dose Adjustments, Precautions, and Monitor.

DRUG/LAB INTERACTIONS

Review of patient drug profile by pharmacist is imperative at time of initiation of aminophylline and with any change in medication regimen. ■ Do not use one **xanthine derivative** concurrently with another **xanthine derivative, ephedrine, or other sympathomimetic drugs.** ■ Xanthines antagonize or potentiate or are themselves antagonized or potentiated by many drug groups. Monitor serum levels as indicated. **Theophylline clearance increased and**

serum levels decreased by aminoglutenide, barbiturates, carbamazepine, isoproterenol, phenytoin, rifampin, smoking, and sulfinpyrazone. Theophylline clearance decreased and serum levels increased by alcohol, allopurinol, beta-adrenergic blockers, cimetidine, ciprofloxacin, clarithromycin, disulfiram, erythromycin, estrogen-containing oral contraceptives, fluvoxamine, interferon alfa-A, methotrexate, mexiletine, pentoxifylline, propafenone, tacrine, thiabendazole, and verapamil. ■ Inhibits **pancuronium;** increased doses of pancuronium may be required to achieve neuromuscular blockade. ■ **Carbamazepine and loop diuretics** (e.g., furosemide) may increase or decrease serum levels. ■ Reduces sedative effect of **benzodiazepines** (e.g., diazepam, midazolam) **and of propofol**; increased doses of sedatives may be required. To avoid respiratory depression, reduce sedative dose if aminophylline is discontinued or if dose is significantly reduced. ■ May decrease **lithium** levels. Dose adjustment and monitoring of lithium levels may be indicated. ■ Concurrent use with **ketamine** may lower aminophylline seizure level. ■ Concurrent use with **ephedrine** may increase nausea, nervousness, and insomnia. ■ May increase **lab values** for free fatty acids, glucose, HDL, LDL, total cholesterol, uric acid, and urinary free cortisol excretion. ■ Caffeine and xanthine metabolites in neonates or patients with renal dysfunction may cause readings from some **immunoassay techniques** to be higher than the actual serum theophylline concentration. ■ Interferes with **dipyridamole-assisted MI perfusion studies.**

SIDE EFFECTS

Headache, insomnia, nausea, vomiting most common when peak serum concentrations are less than 20 mcg/mL. Rarely a severe hypersensitivity reaction of the skin (e.g., exfoliative dermatitis) may occur. Toxicity resulting in death may occur suddenly at levels less than 20 mcg/mL, especially in certain populations (see Precautions); may occur more frequently with serum levels above 20 mcg/mL. Anxiety, arrhythmias (e.g., atrial fibrillation, ventricular fibrillation), cardiac arrest, convulsions, delirium, dizziness, flushing, hyperpyrexia, intractable seizures, nausea, peripheral vascular collapse, persistent vomiting, restlessness, temporary hypotension.

Overdose:

Acute:

Acid/base disturbances, arrhythmias (e.g., sinus tachycardia), hyperglycemia, hypokalemia, seizures (usually with serum concentrations over 100 mcg/mL), vomiting, and death have occurred.

Chronic:

All of the above plus various arrhythmias, seizures (with serum concentration greater than 30 mcg/mL), and death.

ANTIDOTE

With onset of any side effect, discontinue drug and notify physician. ■ Stop the IV infusion and obtain a serum theophylline concentration immediately in any patient on aminophylline who develops nausea or vomiting (particularly repetitive vomiting) or if any other signs of toxicity occur, even if another cause is suspected. ■ For mild symptoms the physician may choose to continue the drug at a decreased dose and rate of administration. All side effects will be treated symptomatically. Maintain adequate ventilation and adequate hydration. Grand mal seizures may not respond to anticonvulsants. Diazepam may be most effective. Treat atrial arrhythmias with verapamil, ventricular arrhythmias with lidocaine or procainamide. Use dopamine for hypotension. Do not use stimulants. Resuscitate as necessary.

Manufacturer's Specific Recommendations for Acute and Chronic Overdose
Acute overdose (e.g., excessive loading dose or excessive infusion rate for less than 24 hours) or chronic overdose (e.g., excessive infusion rate for more than 24 hours): Serum concentration 20 to 30 mcg/mL: Stop the infusion, monitor the patient, and obtain a serum theophylline concentration in 2 to 4 hours to ensure that the concentration is decreasing.
Acute overdose with a serum concentration of 30 to 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL in patients less than 60 years of age: Stop the infusion. Administer multiple-dose, oral-activated charcoal and measures to control emesis. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions. Institute extracorporeal removal if emesis, seizures, or cardiac arrhythmias cannot be adequately controlled.
Acute overdose with a serum concentration greater than 100 mcg/mL or chronic overdose with serum concentrations greater than 30 mcg/mL in patients 60 years or older: Stop the infusion. Consider prophylactic anticonvulsant therapy. Administer multiple-dose oral-activated charcoal and measures to control emesis. Consider extracorporeal removal, even if the patient has not experienced a seizure. Monitor the patient and obtain serial theophylline concentrations every 2 to 4 hours to determine the effectiveness of therapy and to determine further treatment decisions.
Extracorporeal removal: Weigh risk versus benefits. Charcoal hemoperfusion is the most effective and increases theophylline clearance up to sixfold, but hypotension, hypocalcemia, and platelet consumption and bleeding diatheses may occur. Hemodialysis is about as efficient as multiple-dose oral-activated charcoal and has a lower risk of serious complications. Consider hemodialysis when charcoal hemoperfusion is not feasible and multiple-dose oral-activated charcoal is ineffective because of intractable emesis. Serum theophylline concentrations may rebound 5 to 10 mcg/mL after either treatment is discontinued due to redistribution of theophylline from the tissue compartment. Peritoneal dialysis is ineffective,

and exchange transfusions in neonates have been minimally effective.

AMIODARONE HYDROCHLORIDE

(am-ee-**OH**-dah-rohn hy-droh-**KLOR**-eyed)
Nexterone, Pacerone
Antiarrhythmic
pH 4.08

USUAL DOSE

Pretreatment:

See Maternal/Child.

Treatment and Prophylaxis of Ventricular Tachycardia (VT) and Ventricular Fibrillation (VF)

1,000 mg over the first 24 hours in 3 distinct segments; two loading infusions and a maintenance infusion. Use of a dedicated central venous catheter preferred.

Rapid loading infusion:

150 mg specifically diluted solution (1.5 mg/mL) over 10 minutes (15 mg/min). Follow immediately with the slow loading infusion.

Slow loading infusion:

360 mg specifically diluted solution (1.8 mg/mL) at 1 mg/min over the next 6 hours.

Maintenance infusion:

540 mg of 1.8 mg/mL solution at 0.5 mg/min over 18 hours. Maintenance infusion is usually continued at 0.5 mg/min for 48 to 96 hours or until ventricular arrhythmias are stabilized; see Dose Adjustments. Transfer to oral therapy as soon as feasible (guidelines are in package insert).

Treatment of Breakthrough Ventricular Fibrillation (VF) or Hemodynamically Unstable Ventricular Tachycardia (VT)

At any time that breakthrough VF or hemodynamically unstable VT occurs during administration, a supplemental rapid loading infusion (150 mg over 10 minutes) may be repeated. May be specifically diluted 1.5 mg/mL solution or rate of the maintenance infusion (1.8 mg/mL) may be temporarily increased to equal 150 mg (83.33 mL) over 10 minutes. In life-threatening arrhythmias, AHA guidelines state that this rapid loading infusion (150 mg over 10 minutes) may be repeated every 10 minutes as needed and recommend a maximum cumulative dose of 2.2 Gm/24 hr.

Cardiac Arrest (unlabeled)

300 mg (6 mL) or 5 mg/kg as a bolus injection. Flush with 10 mL D5W or NS. Should be given through a separate IV line immediately after the first dose of epinephrine (1 mg)

and before the fourth electrical countershock. Supplemental doses of 150 mg (3 mL) may be given for recurrent bouts of VT/VF. AHA guidelines recommend a first dose of 300 mg IV push and a second dose, if needed, of 150 mg IV push.

Supraventricular Arrhythmias (unlabeled)

150 mg over 10 minutes as a loading dose (15 mg/min). Follow with an infusion of 360 mg over 6 hours (1 mg/min) followed by a maintenance infusion of 0.5 mg/min for 18 hours.

Intravenous to Oral Transition

Guidelines for IV to oral transition are located in manufacturer's literature. See Prescribing Information or consult pharmacist.

PEDIATRIC DOSE

Safety for use in pediatric patients (particularly infants and neonates) not established and not recommended; see Maternal/Child.

Treatment of refractory pulseless VT, VF (unlabeled):

AHA guidelines recommend 5 mg/kg by IV bolus (maximum single dose is 300 mg). May repeat to a maximum of 15 mg/kg/24 hr. Total dose in adolescents is 2.2 Gm/24 hr.

Treatment of perfusing supraventricular and ventricular arrhythmias (unlabeled):

AHA guidelines recommend 5 mg/kg as an infusion over 20 to 60 minutes (maximum single dose 300 mg). May repeat to a maximum of 15 mg/kg/24 hr. Total dose in adolescents is 2.2 Gm/24 hr.

DOSE ADJUSTMENTS

The first 24-hour dose may be individualized for each patient; however, in controlled clinical trials mean daily doses above 2,100 mg were associated with an increased risk of hypotension. Do not exceed an initial infusion rate of 30 mg/min. ■ Rate of maintenance infusion may be increased to achieve effective arrhythmia suppression. ■ Based on experience from clinical studies, a maintenance infusion of up to 0.5 mg/min can be continued for 2 to 3 weeks regardless of the patient's age, renal function, or left ventricular function. ■ One source suggests a reduced dose in hepatic failure. ■ Dose selection should be cautious in the elderly. Reduced initial doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Available as a premixed solution in 1.5 mg/mL and 1.8 mg/mL concentrations or as a vial that must be further diluted. To further dilute vials, do not use evacuated glass intravenous bottles. Use only commercially available D5W solutions in polyolefin or glass containers in any prepared solution that will be given over more than 2 hours. PVC containers are suitable only for dilution of the rapid loading dose; see Compatibility and Precautions.

Rapid-loading infusion:

Dilute 150 mg (3 mL) in 100 mL D5W; concentration is 1.5 mg/mL.

Slow-loading infusion and maintenance infusion:

Dilute 900 mg (18 mL) in 500 mL D5W; concentration is 1.8 mg/mL. Dilutions from 1 to 6 mg/mL have been used for maintenance solutions after the first 24 hours. Use of a central venous catheter is recommended; however, concentrations over 2 mg/mL for longer than 1 hour must be administered through a central venous catheter. Higher concentrations (3 to 6 mg/mL) have caused peripheral vein phlebitis and hepatocellular necrosis; see Precautions.

Cardiac arrest (unlabeled):

Loading dose (300 mg or 5 mg/kg) or supplemental boluses (150 mg) may be given undiluted.

Filters:

Use of a 0.2-micron in-line filter recommended by manufacturer. States “filtering does not affect potency.” Another source suggests no significant loss of drug potency with the use of a 0.22-micron cellulose ester membrane filter.

Storage:

Store ampules and premixed solutions in their carton at CRT. Use solutions diluted in PVC containers within 2 hours; use those diluted in glass or polyolefin containers within 24 hours. Protect from light and freezing.

COMPATIBILITY

Manufacturer recommendations include: Do not use evacuated glass intravenous bottles. Administer through a dedicated IV line (central venous catheter preferred). Absorbs to PVC tubing but loss accounted for in specified dose; follow infusion regimen closely. Leaches out plasticizers, including DEHP, from IV tubing. The degree of leaching increases when the solution is infused at a higher concentration or a slower infusion rate than recommended. Manufacturer lists aminophylline, argatroban, bivalirudin, cefazolin, ceftazidime, digoxin, furosemide, heparin, imipenem-cilastatin, magnesium sulfate, nitroprusside sodium, piperacillin/tazobactam, potassium phosphates, sodium bicarbonate, and sodium phosphates as **incompatible** at the **Y-site** with amiodarone in D5W. Aminophylline, ampicillin/sulbactam, and micafungin in NS are also listed as **incompatible** at the **Y-site**.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Volumetric pump required for administration. Surface properties of diluted solution reduce drop size; use of a drop counter infusion set causes underdosing. Use of a 0.2-micron in-line filter is also recommended. A central venous catheter is recommended for all concentrations and is required for concentrations greater than 2 mg/mL. Adhere to prescribed rates; risk of hypotension is increased in the first hours of treatment and with increased rates; may cause secondary renal or hepatic failure; see Precautions. Do not use plastic containers in a series; could result in air embolism.

Rapid loading infusion or breakthrough treatment of VF/VT:

150 mg over 10 minutes (15 mg/min). Do not exceed a rate of 30 mg/min.

Slow loading infusion:

1 mg/min or 33.3 mL/hr (0.556 mL/min) of 1.8 mg/mL solution for 6 hours.

Maintenance infusion:

0.5 mg/min or 16.6 mL/hr (0.278 mL/min) of 1.8 mg/mL solution for 18 hours. A continuing maintenance solution should deliver 720 mg/24 hr at 0.5 mg/min whether the concentration is 1.8 mg/mL or 6 mg/mL. May be continued at this rate for up to 2 to 3 weeks as described in Usual Dose.

Cardiac arrest (unlabeled):

Loading or supplemental doses by IV bolus injection. Follow with 10 mL flush of D5W or NS through Y-tube or three-way stopcock. May be given through a free-flowing infusion of D5W (D5W or NS may be used for Nexterone). After return of spontaneous circulation (ROSC), initiate the slow loading and maintenance infusions as above.

ACTIONS

An antiarrhythmic agent. Generally considered a Class III antiarrhythmic drug, but possesses characteristics of all four antiarrhythmic classes. Decreases number of VT/VF events. It prolongs the duration of action potentials, depresses conduction velocity, slows conduction and prolongs refractoriness at the AV node, and exhibits some alpha and beta blockade activity. Raises the threshold for VF and may prevent its recurrence. Also has vasodilatory effects that decrease cardiac workload and myocardial oxygen consumption. Uptake by the myocardium is rapid; antiarrhythmic effect is prompt (clinically relevant within hours); however, full effect may take days. Has an exceptionally long half-life. Highly protein bound. Metabolized in the liver by cytochrome P_{450} enzymes (specifically CYP3A4 and CYP2C8). Terminal elimination half-life after a single IV dose ranged from 9 to 36 days. Primarily excreted in bile. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Initiation of treatment and prophylaxis of frequently recurring VF and hemodynamically unstable VT in patients refractory to other therapy. Used until ventricular arrhythmias are stabilized; usually 48 to 96 hours, but may be given for longer periods. ■ Treatment of patients taking oral amiodarone who are unable to take oral medication.

Unlabeled uses:

Conversion of atrial fibrillation to a normal sinus rhythm and maintenance of a normal sinus rhythm. ■ Cardiac arrest with persistent VT or VF if defibrillation, CPR, and vasopressor administration have failed. ■ Control of hemodynamically stable monomorphic VT, polymorphic VT with a normal baseline QT interval, or wide-complex tachycardia of uncertain origin. ■ Control of rapid ventricular rate due to accessory pathway conduction in pre-excited atrial arrhythmias. ■ Heart rate control in patients with atrial fibrillation and heart failure with no accessory pathway. ■ Pharmacologic adjunct to ICD (implantable cardioverter defibrillator) therapy to suppress symptomatic ventricular tachyarrhythmias in otherwise optimally treated patients with heart failure.

CONTRAINDICATIONS

Cardiogenic shock; corneal refractive laser surgery; known hypersensitivity to amiodarone or any of its components, including iodine; marked sinus bradycardia; second- or third-degree AV block unless a functioning pacemaker is available; sinus node dysfunction. See Drug/Lab Interactions.

PRECAUTIONS

Usually administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ Because of the long half-life of amiodarone and its metabolite, the potential for adverse reactions or interactions, as well as observed adverse effects, can persist following amiodarone withdrawal. ■ May cause increases in liver enzymes and bilirubin levels. However, in the majority of patients, liver enzyme elevations either improved during therapy or remained at baseline levels. Abnormal baseline hepatic enzymes are not a contraindication to use. ■ Use of higher than recommended loading dose concentrations and increased rates of administration have been associated with hepatocellular necrosis, hepatic coma, acute renal failure, and death. ■ May worsen existing arrhythmias or precipitate new ones, primarily torsades de pointes or new-onset VF. Deaths have occurred. ■ Correct hypokalemia, hypomagnesemia, and hypocalcemia before use; may exaggerate a prolonged QTc and cause arrhythmias (e.g., torsades de pointes). ■ Combination of amiodarone with other antiarrhythmics that can prolong the QTc interval should be reserved for patients with life-threatening ventricular arrhythmias who do not respond to single agent therapy; see Drug/Lab Interactions. ■ Risk of QTc prolongation is increased with other medications that can prolong the QTc; see Drug/Lab Interactions. ■ Hypotension is the most common side effect. Usually occurs within the first several hours of therapy and appears to be rate-related. Do not exceed initial rates recommended by manufacturer. In some cases, hypotension has been refractory to treatment. Deaths have occurred. See Monitor and Antidote. ■ Drug-related bradycardia that is not dose related can occur. Patients with a predisposition to bradycardia or AV block should be treated with amiodarone in a setting in which a temporary pacemaker is available. ■ May cause visual impairment (e.g., optic neuropathy or optic neuritis); has progressed to permanent blindness. ■ May cause pulmonary toxicity (e.g., ARDS, bronchospasm, cough, dyspnea, hemoptysis, hypoxemia, pulmonary fibrosis, wheezing). Usually seen with long-term oral use, but acute pulmonary toxicity has been reported after IV use. Has progressed to respiratory failure and death. Patients with pre-existing lung disease may be at increased risk. ■ Monitor patients undergoing general anesthesia closely; may increase sensitivity to myocardial depressant and conduction defects of halogenated inhalation anesthetics (hypotension). ■ Use caution in patients with cardiomyopathy, hepatic failure, left ventricular dysfunction, or thyroid dysfunction. ■ May cause hypothyroidism or hyperthyroidism. Amiodarone-induced hyperthyroidism may result in thyrotoxicosis and/or the possibility of arrhythmia breakthrough or aggravation. Deaths have occurred. Severe hypothyroidism and myxedema coma, sometimes fatal, have been reported. ■ Thyroid nodules and/or thyroid cancer have been reported in patients treated with amiodarone. ■ Anaphylactic/anaphylactoid reactions, some fatal, have been reported. ■ See Compatibility and Drug/Lab Interactions.

Monitor:

Continuous ECG and HR monitoring is mandatory to observe for arrhythmias. Watch for QTc prolongation; may worsen existing arrhythmia or precipitate a new arrhythmia, including torsades de pointes. Consider the possibility of hyperthyroidism if new signs of arrhythmia appear. ■ Monitor for bradycardia and AV block. ■ Monitor BP closely to minimize hypotension (occurs frequently with initial rates); see Rate of Administration, Precautions, and Antidote. ■ Confirm patency of vein. Incidence of phlebitis markedly increased with concentrations above 2.5 mg/mL. For infusions longer than 1 hour, do not exceed a concentration of 2 mg/mL unless a central venous line is used. ■ Monitor serum electrolytes and acid-base balance, especially in patients with prolonged diarrhea and those receiving diuretics. ■ Monitor liver enzymes (AST, ALT, GGT) and bilirubin for elevations indicating progressive injury. ■ Monitor pulmonary status (e.g., FiO_2, SaO_2, PaO_2, chest x-ray); baseline pulmonary function tests recommended; repeat as indicated. ■ Monitor thyroid function tests before treatment and periodically thereafter. Patients with a history of thyroid nodules, goiter, or other thyroid dysfunction and the elderly should be monitored closely. Amiodarone is eliminated slowly, and abnormal function tests may persist for weeks or months after it is discontinued. ■ Regular ophthalmic exams, including funduscopy and slit lamp exams, are recommended. Prompt ophthalmic exams recommended at first sign of visual impairment. May require discontinuation of amiodarone therapy. ■ Monitor for S/S of anaphylaxis/anaphylactoid reactions (e.g., cardiac arrest, cold sweat, cyanosis, flushing, hyperhidrosis, hypotension, hypoxia, rash, shock, tachycardia). ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Most manufacturers of corneal refractive laser surgery devices contraindicate this procedure in patients receiving amiodarone. ■ Report promptly any feelings of faintness, difficulty breathing, or pain or stinging along injection site. Review side effect profile, including S/S of hypothyroidism or hyperthyroidism. ■ Effective birth control recommended. ■ Numerous drug interactions. Review all medications, including OTC medications, with physician or pharmacist. ■ Avoid grapefruit juice if transitioned to oral amiodarone.

Maternal/Child:

Category D: can cause fetal harm; avoid pregnancy or use only if benefit to mother justifies risk to fetus. Fetal exposure may increase potential for adverse experiences, including cardiac, thyroid, neurodevelopmental, neurologic, and growth effects in neonates. ■ Discontinue breast-feeding. ■ Safety for use during labor and delivery not established. ■ Safety and effectiveness for use in pediatric patients not established. Use in pediatric patients is not recommended by the manufacturer. ■ Vials contain benzyl alcohol, which has been associated with “gasping syndrome” in neonates (sudden onset of gasping respirations, hypotension, bradycardia, and cardiovascular collapse).

Elderly:

Differences in response between the elderly and younger patients have not been identified; however, clearance is slower and half-life may be doubled (up to 47 days). See Dose Adjustments.

DRUG/LAB INTERACTIONS

Amiodarone has a long half-life; drug interactions may persist long after it is discontinued.

Contraindicated with nelfinavir and ritonavir.

Should not be given concurrently with **ibutilide**. ■ Concurrent use with other **antiarrhythmic agents** (e.g., flecainide, procainamide, quinidine) increases their serum concentrations and may result in additive increases in QT prolongation and serious arrhythmias. Manufacturer recommends reducing the dose of previously given antiarrhythmic agents by 30% to 50% several days after starting amiodarone and then evaluating the need for continued therapy with the other antiarrhythmic agent after the effects of amiodarone have been established. Monitor serum levels if possible. ■ QT prolongation has been reported with concomitant administration of amiodarone and **fluoroquinolones, halogenated inhalation anesthetic agents, macrolide antibiotics, azole antifungals, lithium, loratadine, phenothiazines** (e.g., prochlorperazine, promethazine), **trazodone, tricyclic antidepressants, and grapefruit juice (oral therapy);** see Precautions. ■ May decrease metabolism and increase serum levels of **digoxin.** Reduce digoxin dose by 50% or withdraw completely when amiodarone therapy is initiated. ■ Use with **potassium-depleting diuretics** may lead to increased risk of arrhythmias due to hypokalemia. ■ Inhibits metabolism and increases anticoagulant effect (e.g., increased PT and INR) of **warfarin**. Dose reduction of the anticoagulant and careful monitoring of PT or INR recommended. Effects may persist long after amiodarone is discontinued. ■ Coadministration with dabigatran may result in an elevated serum concentration of dabigatran. ■ May decrease metabolism and increase serum levels of **flecainide, phenytoin, lidocaine, procainamide, quinidine, and theophylline** (aminophylline). May cause toxicity; monitor serum levels. Reduced doses indicated. ■ May decrease metabolism and increase serum levels of **cyclosporine**. Monitor cyclosporine levels and renal function. ■ May increase serum concentration of **methotrexate**. Monitor levels and for S/S of toxicity. ■ Concomitant use with **HMG-CoA reductase inhibitors** that are CYP3A4 substrates (e.g., lovastatin, simvastatin) has been associated with myopathy/rhabdomyolysis. In patients taking amiodarone, limit the dose of lovastatin to 40 mg daily and limit the dose of simvastatin to 20 mg daily. Lower starting and maintenance doses of other CYP3A4 substrates (e.g., atorvastatin) may also be required. ■ Amiodarone clearance increased and plasma levels decreased with **cholestyramine, phenytoin, rifampin, and St. John's wort.** ■ **Cimetidine and protease inhibitors** (e.g., indinavir) may decrease clearance and increase plasma levels of amiodarone. ■ Concomitant use of **drugs with depressant effects on the sinus and AV node** (e.g., beta-blockers, calcium channel blockers) can potentiate the electrophysiologic and hemodynamic effects of amiodarone, resulting in bradycardia, sinus arrest, and AV block. Monitoring of heart rate required. ■ May inhibit conversion of **clopidogrel** to its active metabolite, resulting in ineffective inhibition of platelet aggregation. ■ May inhibit conversion of the prodrug **cyclophosphamide** to its active metabolite. ■ Monitor patients undergoing **general anesthesia** closely. May increase sensitivity to myocardial depressant and conduction defects of **halogenated inhalation anesthetics**. ■ PO use for longer than 2 weeks may decrease metabolism and increase serum levels of **dextromethorphan**. ■ Serious symptomatic bradycardia has occurred with coadministration with **ledipasvir/sofosbuvir** (Harvoni) or with **sofosbuvir** (Sovaldi). Mechanism unknown. Monitor heart rate in patients taking or recently discontinuing amiodarone when starting antiviral treatment. ■ See Precautions.

SIDE EFFECTS

The most important adverse reactions are asystole/cardiac arrest/pulseless electrical activity, AV block, bradycardia, cardiogenic shock, CHF, hypotension, liver function abnormalities, torsades de pointes, and VT. The most common adverse reactions leading to discontinuation of IV amiodarone therapy are asystole/cardiac arrest/pulseless electrical activity, cardiogenic shock, hypotension, and VT. Other adverse reactions that have been reported include abnormal kidney function, atrial fibrillation, atrioventricular block, diarrhea, increased ALT and AST, lung edema, nodal arrhythmia, prolonged QT interval, respiratory disorder, shock, sinus bradycardia, Stevens-Johnson syndrome, thrombocytopenia, VF, and vomiting.

Post-Marketing:

Anemia (aplastic and/or hemolytic), ARDS, confusion, cough, delirium, disorientation, dizziness, dyspnea, erythema multiforme, exfoliative dermatitis, hallucinations, hemoptysis, hypoxia, muscle weakness, myopathy, neutropenia, pancreatitis, pancytopenia, organizing pneumonia (may be fatal), rhabdomyolysis, syndrome of inappropriate antidiuretic hormone secretion (SIADH), toxic epidermal necrolysis (may be fatal) and many other side effects have been reported.

Overdose:

AV block, bradycardia, cardiogenic shock, death, hepatotoxicity, hypotension.

ANTIDOTE

Keep physician informed of all side effects and treat promptly as appropriate; many are life threatening. Monitor hepatic enzymes closely. Reduce rate or discontinue for progressive hepatic injury. Treat hypotension and cardiogenic shock by slowing the infusion rate. Vasopressors, inotropic agents, and volume expansion may be indicated.

Slow infusion rate or discontinue if bradycardia and/or AV block occur; may require a temporary pacemaker. If torsades de pointes occurs, stop all cardioactive drugs (e.g., antiarrhythmics, digoxin, antidepressants, phenothiazines) and normalize electrolytes (e.g., potassium, magnesium). Treat as indicated. Dose reduction or discontinuation of amiodarone may be required if thyroid abnormalities develop. Thyroid hormone supplementation may be required in hypothyroidism. Initiation of antithyroid drugs (e.g., propylthiouracil [PTU]), beta-blockers (e.g., propranolol), and/or temporary corticosteroid therapy may be necessary for treatment of hyperthyroidism. In severe thyrotoxicosis where amiodarone cannot be discontinued, thyroidectomy may be used as treatment. Experience with surgical intervention is limited; could induce thyroid storm. Amiodarone is not dialyzable. Resuscitate as necessary.

AMISULPRIDE

Barhemsys
Dopamine antagonist
pH 4.75 to 5.25

USUAL DOSE

Prevention of postoperative nausea and vomiting (PONV):

5 mg as a single IV injection infused over 1 to 2 minutes at the time of induction of anesthesia.

Treatment of PONV:

10 mg as a single IV injection infused over 1 to 2 minutes in the event of nausea and/or vomiting after a surgical procedure.

DOSE ADJUSTMENTS

No dose adjustment required based on age, sex, race, or in patients with mild to moderate renal impairment (eGFR 30 to 89 mL/min/1.73 M^2). The pharmacokinetics of amisulpride in patients with severe renal impairment (eGFR less than 30 mL/min/1.73 M^2) have not been adequately studied.

DILUTION

Available as a clear, colorless solution in a single-dose vial containing 5 mg/2 mL (2.5 mg/mL). May be administered undiluted.

Storage:

Store unopened vials at CRT. Protect from light. Amisulpride is subject to photodegradation. Administer within 12 hours after the vial is removed from the protective carton.

COMPATIBILITY

Manufacturer states, “Amisulpride is chemically and physically compatible with SWFI, D5W, and NS, which may be used to flush an IV line before or after administration of amisulpride."

RATE OF ADMINISTRATION

A single dose equally distributed over 1 to 2 minutes.

ACTIONS

Amisulpride is a selective dopamine-2 (D2) and dopamine-3 (D3) receptor antagonist. D2 receptors are located in the chemoreceptor trigger zone (CTZ) and respond to the dopamine released from the nerve endings. Activation of CTZ relays stimuli to the vomiting center, which is involved in emesis. Studies in multiple species indicate that D3 receptors in the area postrema also play a role in emesis. Amisulpride has no appreciable affinity for any other receptor types apart from low affinities for 5-HT_{2B} and 5-HT_7 receptors. Plasma protein binding is 25% to 30%. The mean elimination half-life is 4 to 5 hours. Amisulpride is minimally metabolized and does not appear to be metabolized by cytochrome P450 enzymes. Excreted in urine and feces as unchanged drug and metabolites. Secreted in breast milk.

INDICATIONS AND USES

Indicated in adults for:

- Prevention of postoperative nausea and vomiting (PONV), either alone or in combination with an antiemetic of a different class.
- Treatment of PONV in patients who have received antiemetic prophylaxis with an agent of a different class or who have not received prophylaxis.

CONTRAINDICATIONS

Hypersensitivity to amisulpride.

PRECAUTIONS

Causes dose- and concentration-dependent prolongation of the QT interval. Avoid in patients with congenital long QT syndrome and in patients taking droperidol; see Monitor. ■ Avoid use in patients with severe renal impairment (eGFR less than 30 mL/min/1.73 M^2). Amisulpride is substantially excreted by the kidneys, and patients with severe renal impairment may have increased systemic exposure and an increased risk of adverse reactions.

Monitor:

ECG monitoring is recommended in patients with pre-existing arrhythmias/cardiac conduction disorders, electrolyte abnormalities (e.g., hypokalemia or hypomagnesemia), and CHF, and in patients taking other medications (e.g., ondansetron [Zofran]) or with other medical conditions known to prolong the QT interval.

Patient Education:

May cause cardiac arrhythmias. Contact provider immediately for light-headedness, a syncopal episode, or a perceived change in heart rate. ■ Review all prescription and nonprescription medications with a health care professional.

Maternal/Child:

Data unavailable. Use in pregnancy only if potential benefit justifies potential risk. ■ Amisulpride is present in breast milk. Consider pumping and discarding milk for 48 hours after amisulpride administration to reduce infant exposure. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No overall differences in safety or effectiveness were observed between patients 65 years of age and older and younger patients, but greater sensitivity of some older individuals cannot be ruled out. Amisulpride is substantially excreted by the kidneys, and the risk of adverse reactions may be greater in patients with impaired renal function.

DRUG/LAB INTERACTIONS

Reciprocal antagonism of effects occurs between **dopamine agonist** (e.g., levodopa) and amisulpride. Avoid concomitant use. ■ Avoid concomitant use with **droperidol**. Dose- and concentration-dependent QT prolongation caused by both agents may be additive. ■ ECG monitoring is recommended in patients taking **other drugs known to prolong the QT interval** (e.g., ondansetron).

SIDE EFFECTS

Prevention of PONV:

The most common adverse reactions were abdominal distension, chills, hypokalemia, increased blood prolactin concentrations, and procedural hypotension.

Treatment of PONV:

The most common adverse reaction was infusion site pain.

Post-Marketing:

The following adverse reactions have been reported during postapproval chronic oral use of amisulpride outside of the United States. (Amisulpride is not approved for oral dosing or chronic use in the United States.) Reported adverse reactions included agitation, agranulocytosis, angioedema, anxiety, bradycardia, confusional state, dystonia, extrapyramidal disorder, hypersensitivity, hypotension, increased hepatic enzymes, insomnia, neuroleptic malignant syndrome, prolonged QT interval, seizures, somnolence, torsades de pointes, urticaria, and ventricular tachycardia.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed and treat side effects as indicated. There is no specific antidote for an amisulpride overdose. Management includes cardiac monitoring and treatment of severe extrapyramidal symptoms. Weakly dialyzed; hemodialysis should not be used to eliminate the drug.

AMMONIUM CHLORIDE

(ah-**MOH**-nee-um **KLOR**-eyed)
Electrolyte replenisher
Acidifying agent
pH 4 to 6

USUAL DOSE

Pretreatment:

Baseline studies required; see Monitor.

Ammonium chloride:

Dependent on patient condition and tolerance and must be individualized. Monitor serum bicarbonate or CO_2 combining power to determine individualized dose. An initial dose of 1 or 2 vials (100 to 200 mEq) may be used. Dose may also be determined by assessment of the patient's CO_2 combining power. Each gram of ammonium chloride reduces the CO_2 combining power of a 70-kg adult by 1.1 volume %. If edema and/or hyponatremia are absent, the dose can be calculated by measuring the chloride deficit using the following formula:

$$\text{mEq of Chloride ion (as ammonium chloride)} = \text{Chloride deficit (in mEq/L)} \times 0.2 \times \text{Body weight (in kg)}$$

Administer one-half of calculated dose initially and re-evaluate. 26.75% solution contains 5 mEq Cl/mL. 1 mEq equals 53 mg. 1 Gm of ammonium chloride contains 18.7 mEq of NH_4 and 18.7 mEq of Cl.

PEDIATRIC DOSE

Safety and effectiveness for use in pediatric patients not established. 75 mg/kg/24 hr in equally divided doses every 6 hours (18.75 mg/kg every 6 hours) or 1.5 Gm every 6 hours. Maximum dose is 6 Gm/24 hr.

DOSE ADJUSTMENTS

Based on formulas found in Usual Dose.

DILUTION

A single dose (100 to 200 mEq) of 26.75% solution must be diluted with 500 to 1,000 mL NS to achieve the desired 1% to 2% solution.

Pediatric dilution:

A single dose must be diluted with enough NS to achieve a desired concentration equal to or less than 0.4 mEq/mL (1 mEq diluted with 2.5 mL, 5 mEq diluted with 12.5 mL, or

10 mEq diluted with 25 mL yields a concentration of 0.4 mEq/mL). In a specific example, a 5-kg infant would require 93.75 mg or 1.77 mEq (18.75 mg/kg multiplied by 5 kg equals 93.75 mg). 93.75 mg divided by 53 (number of mg/mEq) yields a dose of 1.77 mEq or 0.35 mL (1.77 divided by 5 [number of mEq/mL] equals 0.35 mL). If the desired concentration is 0.4 mEq/mL and you have a dose of 1.77 mEq, it will require dilution to a minimum of 4.4 mL.

Storage:

Store at CRT. If crystals form, warm solution in a water bath to room temperature before administration. Discard unused portions of concentrated and diluted solutions.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Slow infusion rate for pain along venipuncture site. Do not exceed a rate of 5 mL diluted solution/min for adults (approximately 3 hours for an infusion of 1,000 mL).

Pediatric rate:

Do not exceed 1 mEq/kg/hr or 50 mg/kg/hr of properly diluted solution.

ACTIONS

An acidifying agent. Ammonium chloride dissociates into an ammonium cation and a chloride anion. Ammonium ions are converted to urea by the liver, freeing hydrogen ions and chloride ions. Hydrogen ions react with bicarbonate to form water and carbon dioxide (excreted by the lungs). Chloride ions combine with fixed bases (mostly sodium) to produce diuresis. Combined process reduces the alkaline reserve of the body. A compensatory action occurs within the body to limit effectiveness of diuresis within 3 days.

INDICATIONS AND USES

Treatment of hypochloremic states and metabolic alkalosis that may be due to chloride loss from vomiting (including vomiting due to pyloric stenosis in infants), gastric fistula drainage, gastric suction, or excessive use of alkalinizing drugs.

CONTRAINDICATIONS

Impaired renal function. ■ Severe hepatic impairment (can cause ammonia retention, intoxication, and hepatic coma). ■ Metabolic alkalosis with sodium loss resulting in excretion of sodium bicarbonate in the urine (usually due to vomiting of hydrochloric acid or gastric suction).

PRECAUTIONS

For IV use only; do not administer IM or SC. ■ Not recommended for use in patients with high total CO_2 and buffer base secondary to primary respiratory acidosis. ■ Use caution in patients with cardiac edema or pulmonary insufficiency.

Monitor:

Accurate blood chemistry data required before, during, and after therapy to avoid serious metabolic acidosis and deficiencies. Monitor effectiveness of therapy with repeated serum bicarbonate determinations. Replacement of sodium or potassium ions may be required. ■ Confirm patency of vein. ■ Observe respirations closely (increased ventilation at rest and exertional dyspnea indicate acidosis). ■ Monitor closely for metabolic acidosis (coma, confusion, disorientation) and ammonium toxicity (bradycardia, cardiac arrhythmias, coma, irregular breathing, local and general twitching, pallor, retching, sweating, tonic convulsions). ■ Record intake and output.

Maternal/Child:

Category C: safety for use during pregnancy or lactation not established; use only if clearly needed. ■ Safety for use in pediatric patients not established but is used. Use with caution in infants; may produce acidosis, hyperammonemia, and GI irritation; see Pediatric Dose, Dilution, and Rate of Administration.

Elderly:

Consider potential for impaired renal or hepatic function, susceptibility to rapid changes in electrolytes, concomitant disease, or drug therapy.

DRUG/LAB INTERACTIONS

Concurrent administration with **spironolactone** may produce systemic acidosis. ■ **Acidification of urine may alter the excretion of many drugs** (e.g., amphetamines, sulfonylureas [e.g., chlorpropamide], ephedrine, flecainide, methadone, mexiletine) and increase or decrease their effectiveness.

SIDE EFFECTS

Many side effects are caused by ammonia toxicity. Calcium-deficient tetany, cardiac arrhythmias (including bradycardia), coma, convulsions (tonic), depression, disorientation, EEG abnormalities, excitability, fever, glycosuria, headache, hyperglycemia, hypervolemia, hypokalemia, increased rate and depth of breathing (Kussmaul), irregular respiration, metabolic acidosis, nausea, pain along injection site, pallor, phlebitis, retching, skin rash, stupor, sweating, twitching, vomiting, weakness. See Precautions.

ANTIDOTE

For all side effects, reduce rate of administration or discontinue drug and notify the physician. Treat hypokalemia with potassium and tetany with calcium. Sodium lactate or sodium bicarbonate IV may be used to treat acidosis. Resuscitate as necessary.

AMOBARBITAL SODIUM

(am-oh-**BAR**-bih-tal **SO**-dee-um)
Barbiturate
Sedative/hypnotic
Anticonvulsant
pH 9.6 to 10.4

USUAL DOSE

Pretreatment:

See Maternal/Child.

Amobarbital sodium:

Hypnotic:

65 to 200 mg/dose.

Sedative:

30 to 50 mg. May repeat 2 to 3 times daily.

Anticonvulsant:

65 to 500 mg. 1 Gm is the maximum single adult dose.

PEDIATRIC DOSE

Pediatric patients over 6 years:

Same as adult doses.

Pediatric patients under 6 years:

Sedative:

3 to 5 mg/kg/dose.

Anticonvulsant:

3 to 5 mg/kg/dose or 125 mg/M^2.

DOSE ADJUSTMENTS

Reduce dose in impaired renal or hepatic function, usually required in the debilitated or elderly. ■ See Drug/Lab Interactions.

DILUTION

Each 125 mg must be diluted with a minimum of 1.25 mL of SW for injection to make a 10% solution. Inject diluent slowly and rotate vial to dissolve powder. Do not shake. Hydrolyzes in dry or solution form when exposed to air. Solution should be absolutely clear after 5 minutes. Discard powder or solution that has been exposed to air for 30 minutes.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 50 to 100 mg or fraction thereof over 1 minute for adults and 60 mg/M^2 for pediatric patients. Titrate slowly and use only enough medication to achieve desired effect. Do not exceed 1 mL of a 10% solution/min. Rapid injection may cause symptoms of overdose (e.g., serious respiratory depression).

ACTIONS

A sedative, hypnotic barbiturate of intermediate duration with anticonvulsant effects. Amobarbital is a CNS depressant. Onset of action is prompt by the IV route and lasts about 4 to 6 hours. Pain perception is unimpaired. Rapidly absorbed by all body tissues and excreted fairly quickly in changed form in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Control of convulsive seizures due to eclampsia, meningitis, poisons, tetanus, or chorea. ■ Short-term sedation. ■ Narcoanalysis and narcotherapy. ■ Control agitated behavior in acute psychosis.

CONTRAINDICATIONS

History of porphyria, severely impaired liver function especially with any signs of hepatic coma, known hypersensitivity to barbiturates, severe respiratory depression.

PRECAUTIONS

IV route usually reserved for critical situations. Use of large veins preferred to prevent thrombosis. Intra-arterial injection causes gangrene. ■ Treat the cause of a convulsion. ■ Use caution in asthma, cardiovascular diseases, hypertension, hypotension, impaired hepatic or renal function, pulmonary diseases, depressive states after convulsions, shock, and in the elderly. ■ Use caution in the presence of fever, diabetes, hyperthyroidism, or severe anemia; untoward reactions may occur. ■ May be habit-forming; use caution in acute or chronic pain. ■ Status epilepticus can occur from too-rapid withdrawal.

Monitor:

Highly alkaline, determine absolute patency of vein; avoid extravasation. ■ Record BP, pulse, and respiration every 3 to 5 minutes. Keep patient under constant observation. ■ Keep equipment for artificial ventilation available. Maintain a patent airway. ■

Monitor hematopoietic, renal, and hepatic systems in extended therapy. ■ See Drug/Lab Interactions.

Patient Education:

Avoid alcohol or other CNS depressants (e.g., antihistamines, diazepam [Valium]). ■ May be habit-forming. ■ Consider birth control options.

Maternal/Child:

Category D: avoid pregnancy; will cause birth defects. ■ Withdrawal symptoms have occurred in infants born to mothers receiving barbiturates. ■ Drowsiness has been reported in nursing infants. ■ May cause paradoxical excitement in pediatric patients.

Elderly:

See Dose Adjustments. ■ Often have increased sensitivity to barbiturates; may cause marked excitement, depression, confusion, and increased risk of barbiturate-induced hypothermia.

DRUG/LAB INTERACTIONS

Use with extreme caution if any **other CNS depressants** have been given, such as alcohol, narcotic analgesics, anesthetics, antidepressants, antihistamines, hypnotics, MAO inhibitors, phenothiazines, sedatives, neuromuscular blocking antibiotics, and tranquilizers. Potentiation with respiratory depression may occur. ■ Inhibits **corticosteroids, doxycycline, griseofulvin, oral anticoagulants, oral contraceptives, quinidine, theophylline, and beta-adrenergic blockers** (e.g., propranolol). Capable of innumerable interactions with many drugs. ■ May increase orthostatic hypotension with **furosemide** (Lasix). ■ Monitor **phenytoin and barbiturate levels** when both drugs are used concurrently. ■ May inhibit **vitamin D** metabolism with extended use.

SIDE EFFECTS

Average dose:

Depression, dermatitis, facial edema, fever, hypotension, neonatal apnea, respiratory depression (hypoventilation), thrombocytopenic purpura.

Overdose:

Apnea, coma, cough reflex depression, flat EEG (reversible unless hypoxic damage has occurred), hypotension, hypothermia, laryngospasm, pulmonary edema, reflexes (sluggish or absent), renal shutdown, respiratory depression.

ANTIDOTE

Notify the physician of any side effect. Symptomatic and supportive treatment is most important in overdose. Maintain an adequate airway with artificial ventilation if indicated. Keep the patient warm. IV volume expanders (dextran) and other IV fluids will help maintain adequate circulation. Osmotic diuretics (mannitol) or hemodialysis will promote elimination of the drug. Vasopressors (e.g., dopamine) will maintain BP.

AMPHOTERICIN B BBW* ■ AMPHOTERICIN B LIPID-BASED PRODUCTS

(am-foe-**TER**-ih-sin)
Abelcet, AmBisome
Antifungal
Antiprotozoal (AmBisome)
pH 5 to 7 ■ 5 to 6

USUAL DOSE

Pretreatment:

Pretesting and baseline studies required; see Precautions and Monitor.

Each product has different biochemical, pharmacokinetic, and pharmacodynamic properties. They are not interchangeable from dose to dose, in a given patient, between each other or conventional amphotericin.

Abelcet (Amphotericin B Lipid Complex Injection)

Adults and pediatric patients:

5 mg/kg/24 hr as an infusion. Repeat daily until clinical response or mycologic cure.

AmBisome (Amphotericin B Liposome for Injection)

Adults, children, and infants over 1 month of age:

All doses are by infusion.

Empirical therapy in febrile, neutropenic patients:

3 mg/kg/24 hr.

Systemic fungal infections (e.g., *Aspergillus, Candida, Cryptococcus*):

3 to 5 mg/kg/24 hr.

Treatment of cryptococcal meningitis in HIV-infected patients:

6 mg/kg/24 hr.

Visceral leishmaniasis in immunocompetent patients:

3 mg/kg/24 hr on Days 1 through 5. Repeat 3 mg/kg on Day 14 and on Day 21. A repeat course of therapy may be useful if parasitic clearance is not achieved.

Visceral leishmaniasis in immunocompromised patients:

4 mg/kg/24 hr on Days 1 through 5. Repeat 4 mg/kg on Days 10, 17, 24, 31, and 38. During clinical studies parasitic clearance was not achieved or relapse within 6 months

occurred in 88.2% of patients. Usefulness of repeat courses not determined.

Generic (Conventional Amphotericin B)

Adults and pediatric patients:

Begin with a test dose of 0.1 mg/kg up to 1 mg maximum dose in 20 mL D5W. Infuse over 20 to 30 minutes. Determine size of therapeutic dose by intensity of reaction over a 2- to 4-hour period. Usual starting dose is 0.25 mg/kg of body weight/24 hr. Gradually increase dose by 5 to 10 mg/day (0.125 to 0.25 mg/kg in pediatric patients) to a final dose of 0.5 to 0.7 mg/kg. Total daily dose may range up to 1 mg/kg/day, or up to 1.5 mg/kg/24 hr may be given on alternate-day therapy. Several months of therapy are usually required and recommended for cure. Dosage must be adjusted to each specific patient. In some instances, higher doses can be used. Do not exceed a total daily dose of 1.5 mg/kg under any circumstances.

DOSE ADJUSTMENTS

Abelcet:

Full dose usually required; base on SCr and overall patient condition.

AmBisome:

No dose adjustments suggested.

Generic (Conventional):

In all situations, gradual dose increases are essential. Whenever medicine is not given for 7 days or longer, restart treatment at lowest dosage level.

Patients with impaired cardio-renal function or a severe reaction to the test dose:

Initiate with smaller daily doses (i.e., 5 to 10 mg).

Patients who experience amphotericin-induced nephrotoxicity:

One source recommends reducing the total daily dose by 50% or administering the dose every other day.

Severe and rapidly progressive fungal infection:

Initiate treatment with a daily dose of 0.3 mg/kg.

DILUTION

Abelcet:

Available in 100-mg (20-mL) vials. Shake vial until all yellow sediment is dissolved. Maintain aseptic technique. Withdraw an exact total daily dose from one or more vials using one or more syringes and 18-gauge needles. Replace needle(s) on syringe(s) with the 5-micron filter(s) supplied with each vial. A new filter must be used for each 400 mg (80 mL) of Abelcet. Empty syringe contents through filter into an infusion of D5W. 4

mL of diluent (D5W) is required for each 1 mL (5 mg) of Abelcet to achieve a final concentration of 1 mg/mL. For ***pediatric*** and/or fluid-restricted patients (e.g., patients with cardiovascular disease) reduce diluent by half (approximate concentration of 2 mg/mL).

AmBisome:

Reconstitute each 50-mg vial with 12 mL SWFI (without a bacteriostatic agent) to yield 4 mg/mL. Shake vial vigorously for 30 seconds; forms a yellow translucent suspension. Withdraw an exact total daily dose from one or more vials using one or more 20-mL syringes and needles. Replace needle(s) with the 5-micron filter(s) supplied with each vial. A new filter must be used for each 50-mg vial. Empty syringe contents through filter into an infusion of D5W. Use sufficient diluent to achieve a final concentration of 1 to 2 mg/mL, pH 5 to 6. For ***pediatric patients:*** may be further diluted to concentrations of 0.2 to 0.5 mg/mL for infants and small children to provide adequate volume for infusion.

Generic (Conventional):

A 50-mg vial is initially diluted with 10 mL of SWFI (without a bacteriostatic agent); 5 mg equals 1 mL. Shake well until solution is clear. Further dilute each 1 mg in at least 10 mL of D5W. Dextrose must have a pH above 4.2. Concentration of solution must not be greater than 0.1 mg/mL. Do not use any other diluent. Use a sterile 20-gauge or larger needle at each step of the dilution. Maintain aseptic technique. Larger pore 1-micron filters may be used. Use only fresh solutions without evidence of precipitate or foreign matter. Light sensitive; protect from light during administration.

Filters:

Abelcet:

5-micron filter(s) supplied with each vial. A new filter must be used for each 400 mg (80 mL) of Abelcet. Empty syringe contents through filter into an infusion solution. Do not use an in-line filter.

AmBisome:

5-micron filter(s) supplied with each vial. A new filter must be used for each 50-mg vial. Empty syringe contents through filter into an infusion solution. Do not use an in-line filter smaller than 1 micron.

Generic (Conventional):

Larger pore 1-micron filters may be used; see Dilution.

Storage:

Abelcet:

Before reconstitution, refrigerate in carton until time of use and protect from light. Do not freeze. Diluted solution is stable 48 hours if refrigerated and an additional 6 hours at room temperature. Discard unused drug.

AmBisome:

Unopened vials may be stored at temperatures up to 25° C (77° F). Vials reconstituted with SWFI may be refrigerated for up to 24 hours. Do not freeze. Infusion of fully diluted solution must begin within 6 hours. Discard unused drug.

Generic (Conventional):

Before reconstitution, refrigerate vials and protect from light. Do not freeze. Preserve concentrate in refrigerator up to 7 days or 24 hours at room temperature. Use diluted solution promptly.

COMPATIBILITY

All Formulations

In all situations, use a separate infusion line or flush an existing line with D5W before and after administration.

Abelcet

Do not mix with any other diluent, drug, or solution. Use only D5W. Manufacturer states that **compatibility** with any other diluent has not been established.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

AmBisome/Generic

Do not mix with any other diluent, drug, or solution. Use only SWFI for reconstitution and D5W for dilution for infusion. Use of any other solution or the presence of a bacteriostatic agent (e.g., benzyl alcohol) may cause precipitation.

Generic (Conventional)

Compatibility information not available from manufacturer.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

All Amphotericins:

Rapid infusion may cause hypotension, hypokalemia, arrhythmia, and shock. Infusion reactions can occur with all amphotericin B formulations. See Precautions, Side Effects, and Antidote. With all formulations, flush existing line with D5W before and after administration or use a separate IV line.

Abelcet:

Total daily dose as an infusion at 2.5 mg/kg/hr. Contents of diluted solution must be mixed by shaking at least every 2 hours. Do not use an in-line filter.

AmBisome:

Total daily dose as an infusion over 2 hours. Use of a controlled infusion device is recommended. Infusion time may be shortened to a minimum of 1 hour for patients who show no evidence of intolerance or infusion-related reactions. Infusion time may be extended for patient discomfort or acute reactions or if infusion volume is not tolerated. Do not use any in-line filter less than 1 micron.

Generic (Conventional):

Daily dose over 2 to 6 hours by slow IV infusion. Expected reactions usually less severe with slower rate. A minimum 1-micron filter may be used.

ACTIONS

Antifungal antibiotic agents that bind to the sterol component of fungal cell membranes resulting in leakage of cellular contents. May be fungistatic or fungicidal according to body fluid concentration and susceptibility of the fungus. Abelcet is amphotericin B complexed with two phospholipids in a 1:1 drug-to-lipid ratio. AmBisome is amphotericin B intercalated into a liposomal membrane with several components. Assay tests cannot distinguish lipid-based amphotericin from conventional amphotericin B. Modification of amphotericin to the various lipid-based products alters the drug's functional properties. It allows for increased levels of drug at the site of action (usually areas where the fungi are). Overall effect is increased effectiveness with less toxicity. Not effective against bacteria, rickettsiae, or viruses. Long terminal half-life probably reflects a slow redistribution from tissues. Actual distribution to organs is somewhat selective and may help to decide which product is best to use in a given situation. Route of metabolism not known. Excreted very slowly in the urine.

INDICATIONS AND USES

Abelcet:

Treatment of invasive fungal infections in patients who are refractory to or intolerant of conventional amphotericin B therapy.

AmBisome:

Empirical therapy for presumed fungal infection in febrile, neutropenic patients. ■ Treatment of patients with aspergillosis, candida, and/or cryptococcus infections refractory to conventional amphotericin B or in patients in whom renal impairment or unacceptable toxicity precludes the use of conventional amphotericin B. ■ Treatment of visceral leishmaniasis. ■ Treatment of cryptococcal meningitis in HIV-infected patients.

Generic (Conventional):

Treatment of fungal infections that are progressive and potentially fatal, such as aspergillosis, cryptococcosis, blastomycosis, and disseminated forms of candidiasis, coccidioidomycosis, and histoplasmosis, mucormycosis, and sporotrichosis. These infections must be caused by specific organisms. Not recommended for treatment of noninvasive forms of fungal disease in patients with normal neutrophil counts.

Unlabeled uses:

AmBisome has been used to prevent fungal infections in bone marrow transplant patients.

CONTRAINDICATIONS

All amphotericin formulations:

Known sensitivity to amphotericin B or any components of its formulations unless a life-threatening situation is present.

PRECAUTIONS

All Amphotericin Formulations:

Diagnosis should be positively established by culture or histologic study. ■ Close clinical observation is imperative. Anaphylaxis has occurred; emergency equipment and supplies must be available. ■ Infusion reactions are common and usually occur 1 to 3 hours after the start of the infusion. Frequency and severity of reactions generally diminish with subsequent doses. Pretreatment with antipyretics, antihistamines (e.g., diphenhydramine), and/or selective use of corticosteroids may be indicated. ■ Use caution in patients receiving leukocyte transfusions; may cause acute pulmonary toxicity. Separate times of administration as much as possible. ■ Nephrotoxicity is the usual dose-limiting factor for use of conventional amphotericin B. Impairment may improve with dose reduction or alternate-day therapy, but some residual dysfunction is possible. Lipid-based formulations are associated with less nephrotoxicity. Most studies show equivalent or superior effectiveness compared with conventional amphotericin. Introduction of lipid-based products to patients with increased CrCl and BUN from conventional amphotericin has decreased the CrCl and BUN.

Abelcet:

Renal toxicity is dose dependent but has been consistently less nephrotoxic than conventional amphotericin B.

AmBisome:

Incidence of renal toxicity significantly lower than with conventional amphotericin B.

Generic (Conventional):

Should be used primarily for treatment of patients with progressive and potentially life-threatening fungal infections. It should not be used to treat noninvasive forms of fungal disease such as oral thrush, vaginal candidiasis, and esophageal candidiasis in patients with normal neutrophil counts. ■ To prevent overdose, verify product name and dose, especially if dose exceeds 1.5 mg/kg. ■ Therapy is often initiated in infusion centers. ■ A small amount of heparin added to the infusion may reduce the incidence of thrombophlebitis. ■ Meperidine (Demerol), nonsteroidal anti-inflammatory agents (e.g., ibuprofen), or hydrocortisone before administration may prevent febrile reactions, including chills; corticosteroids not recommended for concomitant use in other situations because they exaggerate hypokalemia. ■ Prophylactic antiemetics and antihistamines are also appropriate.

Monitor:

All amphotericin formulations: Obtain baseline CBC, PT, serum electrolytes, renal (e.g., creatine kinase, BUN, SCr) and liver function (e.g., ALT, AST) tests. Repeat frequently during therapy; recommended weekly. Monitor PT as indicated during therapy. ■ Discontinue or reduce dose until renal function improves if increase in BUN or SCr is clinically significant. Side effects (e.g., hypokalemia, hypomagnesemia, impaired renal function) may be life threatening. ■ Monitor vital signs and I&O. Record every 30 minutes for up to 4 hours after infusion is complete. ■ Monitor for S/S of hypersensitivity or infusion reactions (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria). ■ Encourage fluids to maintain hydration.

Patient Education:

All amphotericin formulations:

Review all medical conditions and medications before beginning treatment. ■ Discomfort associated with infusion. ■ Promptly report S/S of an acute reaction (e.g., anorexia, chills, fever, headache, hypotension, nausea or vomiting, shortness of breath). ■ Long-term therapy required to effect a cure. ■ Report diarrhea, fever, increased or decreased urination, loss of appetite, sore throat, stomach pain, and any unusual bleeding or bruising, tiredness, or weakness. ■ Maintain adequate hydration.

Maternal/Child:

All amphotericin formulations:

Category B: has been used successfully during pregnancy but adequate studies not available. Use only if clearly needed. ■ Safety for use in breast-feeding and pediatric patients not established. Discontinue nursing. ■ Conventional amphotericin B has been used in pediatric patients. Lipid-based preparations have been used in pediatric patients without any unexpected side effects. Safety of use of AmBisome in infants under 1 month of age not established.

Elderly:

Consider age-related impaired body functions. Lipid-based preparations have been used without unexpected side effects.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been done for lipid-based preparations, but interactions similar to conventional amphotericin B are expected. ■ **Corticosteroids** will increase hypokalemia and may cause arrhythmias. Use with caution only if indicated to control drug reactions or, if necessary, monitor serum electrolytes and cardiac function closely. ■ Hypokalemic effect may be increased with **thiazides,** may potentiate **digoxin** toxicity, and/or may enhance the curariform effect of **neuromuscular blocking agents**; monitor serum potassium levels. ■ Avoid use or use extreme caution with other **nephrotoxic drugs** (e.g., **aminoglycosides, selected antibiotics** [e.g., vancomycin], **anesthetics, antituberculars** [e.g., capreomycin], **diuretics, pentamidine**). Nephrotoxic effects are additive. Frequent monitoring of renal function indicated if any other nephrotoxic drug must be used. ■ Nephrotoxicity and myelotoxicity are both increased when given concurrently with **zidovudine**. ■ Potentiates nephrotoxicity of **cyclosporine;** alternate immunosuppressive therapy recommended. ■ Concurrent use with **antineoplastic agents** (e.g., cisplatin, methotrexate) **or radiation therapy** may increase renal toxicity and incidence of bronchospasm and hypotension. ■ Enhances antifungal effects of **flucytosine and other anti-infectives.** May increase toxicity. ■ Antagonism between amphotericin B and **imidazole antifungals** (e.g., ketoconazole, miconazole, fluconazole) has been reported. ■ Acute pulmonary toxicity occurred in patients receiving **leukocyte transfusion;** separate administration times as much as possible. ■ **False elevations of serum phosphate** may occur if patient samples are analyzed using the PHOSm assay.

SIDE EFFECTS

Lipid-Based Preparations:

Most side effects similar to conventional amphotericin B but occur with less frequency and intensity. Acute reactions, including fever and chills, may occur within 1 to 3 hours of starting the infusion. Infusion-related cardiorespiratory reactions may include dyspnea, hypertension, hyperventilation, hypotension, hypoxia, tachycardia, and vasodilation. Arrhythmia, bronchospasm, and shock can occur. Anaphylaxis and cardiac arrest from overdose have been reported.

Generic (Conventional):

Common even at doses below therapeutic; may begin to occur within 15 to 20 minutes: anorexia, chills, convulsions, diarrhea, fever, headache, phlebitis, vomiting. Anaphylactoid reactions, anemia, cardiac disturbances (including fibrillation and arrest), coagulation defects, hypertension, hypokalemia, hypotension, and numerous other side effects occur fairly frequently. Renal function impaired in 80% of patients. May reverse after treatment ends, but some permanent damage likely.

Post-Marketing:

AmBisome:

Agranulocytosis, angioedema, bronchospasm, cyanosis/hypoventilation, edema, erythema, hemorrhagic cystitis, pulmonary edema, rhabdomyolysis.

ANTIDOTE

All Amphotericin Formulations:

Notify the physician of all side effects. Many are reversible if the drug is discontinued. Some will respond to symptomatic treatment. Acute reactions (e.g., fever, chills, hypotension, nausea, and vomiting) usually lessen with subsequent doses. These acute infusion-related reactions can be managed by pretreatment with antipyretics, antihistamines, and/or corticosteroids or reduction of the rate of infusion and prompt treatment with antihistamines and/or corticosteroids and meperidine (Demerol) for chills. If anaphylaxis or serious respiratory distress occurs, discontinue amphotericin and treat as necessary. Give no further infusions. Hemodialysis not effective in overdose. Discontinue if BUN and alkaline phosphatase are abnormal. Dantrolene has been used to prevent (50 mg PO) or treat (50 mg IV) severe, shaking chills.

Generic (Conventional):

Administration of conventional amphotericin B on alternate days may decrease the incidence of some side effects. Urinary alkalinizers may minimize renal tubular acidosis.

Abelcet:

Overdose has caused cardiac arrest. Discontinue drug and treat symptomatically.

AMPICILLIN SODIUM

(am-pih-**SILL**-in **SO**-dee-um)
Antibacterial
(penicillin)
pH 8 to 10

USUAL DOSE

Range is from 1 to 12 Gm/24 hr for adults and pediatric patients weighing 20 kg or more. Larger doses may be indicated based on the seriousness of the infection. Some clinicians suggest a weight of 40 kg to receive adult dose range.

Respiratory tract or skin and skin structure infections:

250 to 500 mg every 6 hours.

GI or GU infections:

500 mg every 6 hours.

Septicemia or bacterial meningitis:

8 to 14 Gm or 150 to 200 mg/kg/24 hr in equally divided doses every 3 to 4 hours (18.75 to 25 mg/kg every 3 hours or 25 to 33.3 mg/kg every 4 hours). Administer IV a minimum of 3 days; then may be given IV or IM.

Listeriosis:

50 mg/kg every 6 hours.

Prevention of bacterial endocarditis in dental or respiratory tract surgery or instrumentation:

2 Gm of ampicillin 30 minutes before procedure.

Prevention of bacterial endocarditis in GI, GU, or biliary tract surgery or

instrumentation:

Low to moderate risk: A single dose of 2 Gm of ampicillin 30 minutes before procedure. ***Moderate to high risk:*** 2 Gm of ampicillin in conjunction with gentamicin 1.5 mg/kg (up to 80 mg) 30 minutes before procedure. Repeat 1 Gm of ampicillin or give oral amoxicillin 1 Gm in 6 hours.

Prophylaxis in high-risk cesarean section patients:

1 to 2 Gm immediately after clamping cord.

Prophylaxis of neonatal group B *Streptococcal* disease:

2 Gm to the mother during labor. Should be given at least 4 hours before delivery to ensure amniotic fluid concentrations and placental transfer of ampicillin. May repeat 1 to 2 Gm every 4 to 6 hours until delivery. Continue treatment postpartum if active signs of maternal infection develop. Routine use of prophylaxis in neonates born to these mothers is not recommended; risk must be assessed on an individual basis for each infant.

Leptospirosis (unlabeled):

500 mg to 1 Gm every 6 hours.

Typhoid fever (unlabeled):

25 mg/kg every 6 hours.

PEDIATRIC DOSE

Range is from 25 to 400 mg/kg of body weight/24 hr for pediatric patients weighing less than 20 kg. Some clinicians suggest a weight up to 40 kg is appropriate for pediatric use. Do not exceed adult dose or 12 Gm.

Respiratory tract or skin and skin structure infections:

25 to 50 mg/kg/24 hr in equally divided doses every 4 to 6 hours (4.16 to 8.3 mg/kg every 4 hours or 6.25 to 12.5 mg/kg every 6 hours).

GI or GU infections:

50 to 100 mg/kg/24 hr in equally divided doses every 6 hours (12.5 to 25 mg/kg every 6 hours).

Septicemia or bacterial meningitis:

100 to 200 mg/kg/24 hr in equally divided doses every 3 to 4 hours (12.5 to 25 mg/kg every 3 hours or 16.6 to 33.3 mg/kg every 4 hours).

Empiric treatment of bacterial meningitis in infants and children 2 months to 12 years of age:

Some clinicians recommend 200 to 400 mg/kg/24 hr in equally divided doses every 4 to 6 hours (33.3 to 66.6 mg/kg every 4 hours to 50 to 100 mg/kg every 6 hours). Given in conjunction with chloramphenicol. Satisfactory response should occur within 48 hours or initiate alternate therapy. Administer any regimen IV a minimum of 3 days, then may be given IV or IM.

Prevention of bacterial endocarditis in dental or respiratory tract surgery or instrumentation:

50 mg/kg of ampicillin 30 minutes before procedure.

Prevention of bacterial endocarditis in GI, GU, or biliary tract surgery or instrumentation:

Low to moderate risk: A single dose of 50 mg/kg 30 minutes before procedure. ***Moderate to high risk:*** 50 mg/kg of ampicillin in conjunction with gentamicin 1.5 mg/kg (up to 80 mg) 30 minutes before procedure. Repeat 25 mg/kg of ampicillin or oral amoxicillin in 6 hours.

NEONATAL DOSE

Age up to 7 days:

Weight less than 2,000 Gm: 25 mg/kg every 12 hours. ***2,000 Gm or more:*** 25 mg/kg every 8 hours.

Over 7 days of age:

Weight less than 1,200 Gm: 25 mg/kg every 12 hours. ***1,200 to 2,000 Gm:*** 25 mg/kg every 8 hours. ***More than 2,000 Gm:*** 25 mg/kg every 6 hours.

Empiric treatment of bacterial meningitis in neonates and infants under 2 months of age:

100 to 300 mg/kg/24 hr in equally divided doses (e.g., 33.3 to 100 mg/kg every 8 hours) in conjunction with IM gentamicin. Administer any regimen IV a minimum of 3 days, then may be given IV or IM.

Bacterial meningitis in neonates and infants under 2 months of age:

Age up to 7 days:

Weight less than 2,000 Gm:

50 to 75 mg/kg every 12 hours.

2,000 Gm or more:

50 to 75 mg/kg every 8 hours.

Over 7 days of age:

Weight less than 2,000 Gm:

50 mg/kg every 8 hours.

2,000 Gm or more:

50 mg/kg every 6 hours.

DOSE ADJUSTMENTS

Patients with a CrCl of 10 to 50 mL/min may require the usual dose every 6 to 12 hours. Reduce dose by increasing interval to 12 to 24 hours in severe renal impairment (CrCl less than 10 mL/min). Another source suggests no dose adjustment with a CrCl of 30 mL/min or greater and dosing every 8 hours for a CrCl of 10 mL/min or less. Administer 250 mg every 12 hours to peritoneal dialysis patients. Hemodialysis patients should receive 1 to 2 Gm after dialysis on dialysis days.

DILUTION

Each 500 mg or fraction thereof must be reconstituted with at least 5 mL of SWFI. Use within 1 hour of reconstitution. May be further diluted in 50 mL or more of selected IV solutions. Stable for 8 hours at concentrations up to 30 mg/mL in NS, LR, sodium lactate, or SWFI. Stable in D5/$^1/_2$NS or 10% invert sugar in water for 4 hours at concentrations up to 2 mg/mL. Stable in D5W for 4 hours at concentrations up to 2 mg/mL but only for 2 hours at concentrations up to 20 mg/mL. Must be administered before stability expires.

COMPATIBILITY

Inactivated in solution with aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over 3 to 5 minutes (for 125 to 500 mg) over 10 to 15 minutes (for 1 to 2 Gm). When given by IV injection. In 100 mL or more of solution, administer at prescribed infusion rate but never exceed IV injection rate. Too-rapid injection may cause seizures.

ACTIONS

A semi-synthetic penicillin. Bactericidal against many gram-positive and some gram-negative organisms. Appears in all body fluids. Appears in cerebrospinal fluid only if inflammation is present. Crosses the placental barrier. Excreted in urine. Secreted in breast milk.

INDICATIONS AND USES

Highly effective against severe infections caused by gram-positive and some gram-negative organisms (e.g., respiratory tract, skin and skin structure, GI and GU, bacterial meningitis, endocarditis, listeriosis, septicemia). Not effective with penicillinase-producing staphylococci. ■ Prevention of bacterial endocarditis in dental and respiratory tract surgery or instrumentation. ■ Prevention of bacterial endocarditis in

GI, GU, or biliary surgery or instrumentation. Used concurrently with gentamicin. ■ Drug of choice during labor for prevention of neonatal group B streptococcal infections.

Unlabeled uses:

Prophylaxis in high-risk cesarean section patients. Treatment of leptospirosis. Treatment of typhoid fever.

CONTRAINDICATIONS

Known penicillin or cephalosporin sensitivity (not absolute); see Precautions. Infectious mononucleosis because of increased incidence of rash.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients undergoing penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to ampicillin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ampicillin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of this drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ampicillin. ■ Side effects increased in some patients; see Side Effects.

Monitor:

Watch for early symptoms of hypersensitivity reactions, especially in individuals with a history of allergic problems. ■ AST may be increased. Renal, hepatic, and hematopoietic function should be checked during prolonged therapy. ■ May cause thrombophlebitis; observe carefully and rotate infusion sites.

Patient Education:

May require alternate birth control. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: use only if clearly needed. ■ May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Elimination rate markedly reduced in neonates.

Elderly:

Consider degree of age-related impaired renal function.

DRUG/LAB INTERACTIONS

Streptomycin potentiates bactericidal activity against enterococci. ■ May be used concurrently with **aminoglycosides** (e.g., gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, and tetracyclines); may interfere with bactericidal action. ■ Concomitant use with **beta-adrenergic blockers** may increase risk of anaphylaxis and inhibit treatment. ■ Potentiated by **probenecid;** toxicity may result. ■ Increased risk of bleeding with **heparin.** ■ May decrease clearance and increase toxicity of **methotrexate.** ■ Decreases effectiveness of **oral contraceptives;** breakthrough bleeding or pregnancy could result. ■ Ampicillin-induced skin rash potentiated by **allopurinol**. ■ False-positive glucose reaction with **Clinitest and Benedict's or Fehling's solution.** ■ May cause **false values** in other lab tests; see literature.

SIDE EFFECTS

Primarily hypersensitivity reactions such as anaphylaxis, exfoliative dermatitis, rashes, and urticaria. May cause CDAD. Hypersensitivity myocarditis can occur (fever, eosinophilia, rash, sinus tachycardia, ST-T changes, and cardiomegaly). Anemia, leukopenia, and thrombocytopenia have been reported. Thrombophlebitis will occur with long-term use. Higher than normal doses may cause neurologic adverse reactions including convulsions, especially with impaired renal function. Incidence of side effects increased in patients with viral infections or those taking allopurinol.

ANTIDOTE

Notify the physician of any side effect. For severe symptoms, discontinue the drug, treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids), and resuscitate as necessary. Hemodialysis is effective in overdose. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated.

AMPICILLIN SODIUM AND SULBACTAM SODIUM

(am-pih-**SILL**-in **SO**-dee-um and sull-**BACK**-tam **SO**-dee-um)
Unasyn
Antibacterial (penicillin and beta-lactamase inhibitor)
pH 8 to 10

USUAL DOSE

Adults and pediatric patients weighing 40 kg or more:

1.5 to 3 Gm every 6 hours (1 Gm ampicillin with 0.5 Gm sulbactam to 2 Gm ampicillin with 1 Gm sulbactam). All commercial preparations in the United States have a 2;1 ratio of ampicillin to sulbactam (e.g., 1.5 Gm = 1 Gm ampicillin plus 0.5 Gm sulbactam). Do not exceed 4 Gm ***sulbactam***/24 hr. ***All doses in this monograph include ampicillin and sulbactam within the recommended dose.***

PEDIATRIC DOSE

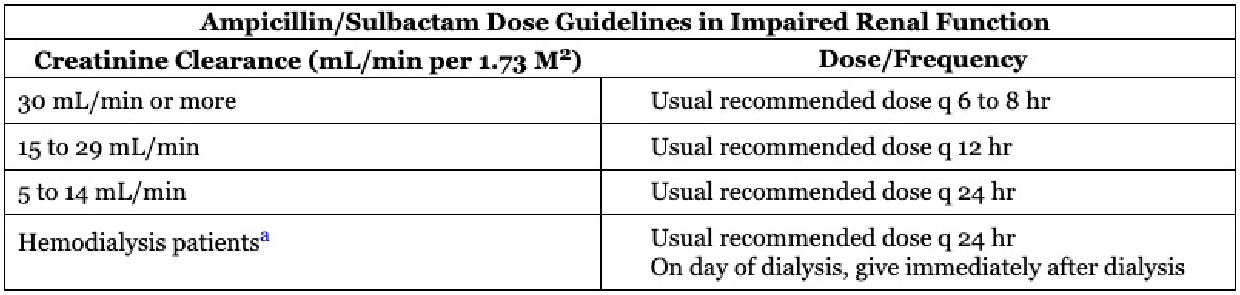
IV use for more than 14 days is not recommended. See comments under Usual Dose.

Skin and skin structure infections in pediatric patients over 1 year of age and less than 40 kg:

300 mg/kg/day (200 mg/kg ampicillin and 100 mg/kg sulbactam) in equally divided doses as an infusion every 6 hours (75 mg/kg every 6 hours).

DOSE ADJUSTMENTS

May be indicated in the elderly. ■ Reduce total daily dose in impaired renal function according to the following chart.



Ampicillin/Sulbactam Dose Guidelines in Impaired Renal Function

Creatinine Clearance (mL/min per 1.73 M^2)	Dose/Frequency
30 mL/min or more	Usual recommended dose q 6 to 8 hr
15 to 29 mL/min	Usual recommended dose q 12 hr
5 to 14 mL/min	Usual recommended dose q 24 hr
Hemodialysis patients[a]	Usual recommended dose q 24 hr On day of dialysis, give immediately after dialysis

[a] One source recommends 1.5 to 3 Gm every 12 to 24 hours for hemodialysis patients, given after dialysis on dialysis days. A dose of 3 Gm/24 hr has been recommended for peritoneal dialysis patients.

DILUTION

Each 1.5 Gm or fraction thereof must be initially reconstituted with 4 mL of SWFI (375 mg/mL). Allow to stand to dissipate foaming. Solution should be clear and colorless to pale yellow. Must be further diluted to a final concentration of 3 to 45 mg/mL in one of the following solutions and given by slow IV injection or as an intermittent IV infusion: D5W, D5/$^{1}/_{2}$NS, LR, or NS. Also available in piggyback vials, pharmacy bulk packages, and ADD-Vantage vials for use with ADD-Vantage infusion containers.

Storage:

Store at CRT before dilution. Stability of different concentrations in each solution varies (see literature).

COMPATIBILITY

May be inactivated in solution with aminoglycosides (e.g., amikacin, gentamicin). Do not mix in the same solution. Appropriate spacing and/or separate sites required. See Drug/Lab Interactions.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over a minimum of 10 to 15 minutes.

Intermittent IV:

A single dose over 15 to 30 minutes or longer, depending on amount of solution. Too-rapid injection may cause seizures.

ACTIONS

An antibacterial combination consisting of the semi-synthetic penicillin, ampicillin sodium, and the beta-lactamase inhibitor sulbactam sodium. The addition of sulbactam extends the antibacterial spectrum of ampicillin to include many bacteria normally resistant to it and to other beta-lactam antibacterials. The antibacterial combination has a broad spectrum of bactericidal activity against selected gram-positive, gram-negative, and anaerobic organisms (see literature). Inhibits bacterial cell wall synthesis. Peak serum levels achieved by end of infusion. Widely distributed into many body tissues and fluids. Half-life is 1 hour. Crosses the placental barrier. Excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of skin and skin structure, intra-abdominal, and gynecologic infections due to susceptible strains of specific organisms.

CONTRAINDICATIONS

History of serious hypersensitivity reactions (e.g., anaphylaxis or Stevens-Johnson syndrome) to ampicillin, sulbactam, or other beta-lactam antibacterial drugs (e.g., penicillins and cephalosporins). ■ Patients with a previous history of cholestatic jaundice/hepatic dysfunction associated with ampicillin/sulbactam. ■ Infectious mononucleosis because of increased incidence of rash.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported in patients on penicillin therapy; most likely to occur in patients with a history of penicillin allergy or sensitivity to multiple allergens. There have been reports of individuals with a history of penicillin hypersensitivity experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Hepatic dysfunction, including hepatitis and cholestatic jaundice, has been associated with the use of ampicillin/sulbactam. Hepatic toxicity is usually reversible; however, deaths have been reported. ■ May cause severe skin reactions (e.g., acute generalized exanthematous pustulosis [AGEP], dermatitis exfoliative, erythema multiforme, Stevens-Johnson syndrome [SJS], and toxic epidermal necrolysis [TEN]). ■ Studies indicated to determine the causative organism and susceptibility to ampicillin/sulbactam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ampicillin and sulbactam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of this drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ampicillin and sulbactam.

Monitor:

Watch for early symptoms of hypersensitivity reactions, especially in individuals with a history of allergic problems. ■ Monitor for possible skin reactions. If a skin rash develops, monitor closely and discontinue if lesions progress. ■ AST may be increased. Renal, hepatic, and hematopoietic function should be checked during prolonged therapy. Hepatic function should be monitored at regular intervals in patients with hepatic impairment. ■ May cause thrombophlebitis. Observe carefully and rotate infusion sites.

Patient Education:

Promptly report any S/S of a hypersensitivity reaction (e.g., itching, rash, wheezing), fever, sore throat, unusual bleeding or bruising, severe stomach cramps and/or diarrhea, or seizures. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Animal studies have not shown adverse effects on fertility or in the fetus. Use only if clearly needed. ■ Use caution with breast-feeding. May cause diarrhea, candidiasis, or allergic response in nursing infants. ■ Safety for IV use in pediatric patients over 1 year of age has been established for skin and skin structure infections but not for other uses; however, it is in use. Elimination rate markedly reduced in neonates. ■ Safety and effectiveness of IM use in pediatric patients not established.

Elderly:

Consider degree of age-related impaired renal function. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Concurrent use with probenecid may result in increased and prolonged ampicillin and sulbactam blood levels. ■ Frequently used concomitantly with **aminoglycosides** (e.g., gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer at separate sites. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines);

may interfere with bactericidal action. ■ May decrease clearance and increase toxicity of **methotrexate.** ■ Ampicillin-induced skin rash potentiated by **allopurinol**. ■ False-positive glucose reaction with **Clinitest and Benedict's or Fehling's solution.** ■ May cause **false values** in other lab tests; see literature.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis, is possible. Diarrhea and rash occur most frequently. Abdominal distension; burning, discomfort, and pain at injection site; candidiasis; chest pain; chills; decreased hemoglobin, hematocrit, RBC, WBC, lymphocytes, neutrophils, and platelets; decreased serum albumin and total protein; dysuria; edema; epistaxis; erythema; facial swelling; fatigue; flatulence; glossitis; headache; increased alkaline phosphatase, BUN, creatinine, LDH, AST, ALT; increased basophils, eosinophils, lymphocytes, monocytes, and platelets; itching; malaise; mucosal bleeding; nausea and vomiting; phlebitis; RBCs and hyaline casts in urine; substernal pain; thrombophlebitis; tightness in throat; and urine retention can occur. May cause CDAD. Higher than normal doses may cause neurologic adverse reactions, including convulsions, especially with impaired renal function.

Post-Marketing:

Abdominal pain, abnormal hepatic function, acute generalized exanthematous pustulosis, agranulocytosis, angioedema, black "hairy" tongue, cholestasis, cholestatic hepatitis, convulsions, dizziness, dyspepsia, dyspnea, erythema multiforme, exfoliative dermatitis, gastritis, hemolytic anemia, hyperbilirubinemia, jaundice, melena, positive direct Coombs' test, Stevens-Johnson syndrome, stomatitis, thrombocytopenic purpura, toxic epidermal necrolysis, tubulointerstitial nephritis, and urticaria.

ANTIDOTE

Notify the physician of any side effect. For severe symptoms, discontinue the drug, treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be effective in overdose.

ANGIOTENSIN II INJECTION

(an-jee-oh-**TEN**-sin too)
Giapreza
Peptide hormone
Vasopressor
pH 5.5

USUAL DOSE

Titrate to effect for each individual patient. Recommended starting dose is 20 nanograms (ng)/kg/min via continuous IV infusion. Use of a central venous line is recommended. Monitor blood pressure response and titrate angiotensin II every 5 minutes by increments of up to 15 ng/kg/min as needed to achieve or maintain target blood pressure. Do not exceed 80 ng/kg/min during the first 3 hours of treatment.

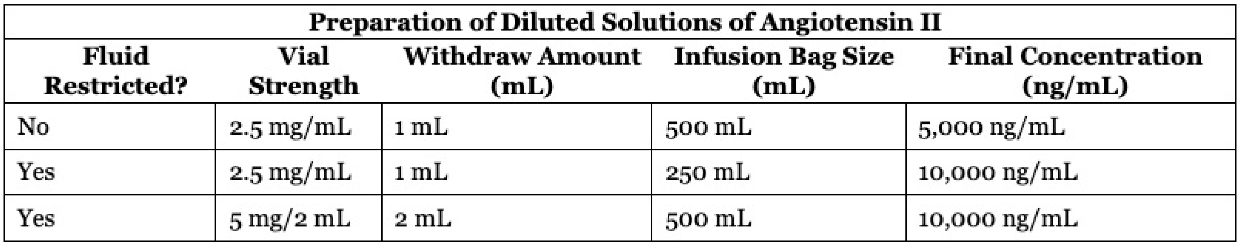
Once the underlying shock has sufficiently improved, down-titrate every 5 to 15 minutes by increments of up to 15 ng/kg/min based on blood pressure. Maintenance doses should not exceed 40 ng/kg/min. Doses as low as 1.25 ng/kg/min may be used.

DOSE ADJUSTMENTS

See Usual Dose. ■ No dose adjustments required based on age, sex, or impaired renal or hepatic function.

DILUTION

Available in sterile vials containing 2.5 mg/mL or 5 mg/2 mL. Must be diluted in NS. Dilute the contents of one vial in 250 to 500 mL of NS to achieve a final concentration of 5,000 ng/mL or 10,000 ng/mL according to the following chart.



Preparation of Diluted Solutions of Angiotensin II

Fluid Restricted?	Vial Strength	Withdraw Amount (mL)	Infusion Bag Size (mL)	Final Concentration (ng/mL)
No	2.5 mg/mL	1 mL	500 mL	5,000 ng/mL
Yes	2.5 mg/mL	1 mL	250 mL	10,000 ng/mL
Yes	5 mg/2 mL	2 mL	500 mL	10,000 ng/mL

Filters:

Specific information not available.

Storage:

Before use, refrigerate vials at 2° to 8° C (36° to 46° F). Diluted solution may be stored at RT or under refrigeration. Discard prepared solution after 24 hours whether stored under refrigeration or at RT. After use, discard vial and any unused portion of the drug product.

COMPATIBILITY

Must be diluted in NS. Specific information on **compatibility** with other fluids or drugs is not available.

RATE OF ADMINISTRATION

See Usual Dose. For IV infusion only. Administration through a central venous line is recommended.

ACTIONS

A synthetic form of human angiotensin II. Angiotensin II is a naturally occurring peptide hormone of the renin-angiotensin-aldosterone system (RAAS). It raises blood pressure by vasoconstriction and increased aldosterone release. Direct action of angiotensin II on the vessel wall is mediated by binding to the G-protein–coupled angiotensin II receptor type 1 on vascular smooth muscle cells, which stimulates calcium/calmodulin-dependent phosphorylation of myosin and causes smooth muscle contraction. Median time to reach the target mean arterial pressure end point is approximately 5 minutes. Half-life is less than 1 minute. Metabolized by aminopeptidase A and angiotensin-converting enzyme 2 to angiotensin-(2-8) [angiotensin III] and angiotensin-(1-7), respectively in plasma, erythrocytes, and many of the major organs (i.e., intestine, kidney, liver, and lung).

INDICATIONS AND USES

Treatment of hypotension in adults with septic or other distributive shock.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

A higher incidence of arterial and venous thrombotic and thromboembolic events occurred in patients receiving angiotensin II compared with placebo-treated patients. Deep venous thromboses were the major occurrence. Concurrent venous thromboembolism (VTE) prophylaxis is recommended.

Monitor:

Monitor vital signs. Continuous monitoring is indicated in these critically ill patients. ■ Monitor for S/S of potential thromboembolic events, and administer VTE prophylaxis. ■ See Drug/Lab Interactions.

Maternal/Child:

Published data on use in pregnancy are not available. However, septic or other distributive shock is a medical emergency that can be fatal if left untreated. Delaying treatment in pregnant women with hypotension associated with septic or other distributive shock is likely to increase the risk of maternal and fetal morbidity and mortality. ■ No data available on the presence of angiotensin II in human milk, the effects on the breast-fed infant, or the effects on milk production. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No significant difference in safety or effectiveness between patients 65 years of age or older and younger patients.

DRUG/LAB INTERACTIONS

Response to angiotensin II may be increased with concomitant use of **angiotensin-converting enzyme (ACE) inhibitors**. ■ Response to angiotensin II may be decreased with concomitant use of **angiotensin II receptor blockers (ARBs)**.

SIDE EFFECTS

Thromboembolic events, including arterial and venous thrombotic events and deep vein thrombosis, are the most common adverse reactions. Acidosis, delirium, fungal infection, hyperglycemia, peripheral ischemia, tachycardia, and thrombocytopenia have also been reported.

Overdose:

Hypertension, necessitating close monitoring and supportive care.

ANTIDOTE

Notify the physician of all side effects or unexpected changes in vital signs. For accidental overdose with hypertension, reduce rate or temporarily discontinue until condition stabilizes. Monitor and provide supportive care as indicated. Effects are expected to be brief because the half-life of angiotensin II is less than 1 minute. Should a hypersensitivity reaction occur, treat as indicated (e.g., antihistamines, epinephrine, corticosteroids). Resuscitate if indicated.

ANIDULAFUNGIN

(a-**nid**-yoo-luh-**FUN**-jin)
Eraxis
Antifungal (echinocandin)

USUAL DOSE

Pretreatment:

Pretesting and baseline studies required; see Monitor and Maternal/Child.

Candidemia and other *Candida* infections (intra-abdominal abscess and peritonitis):

Begin with a ***loading dose*** of 200 mg as an infusion on Day 1. Follow with a daily dose of 100 mg as an infusion beginning on Day 2. Base duration of treatment on patient’s clinical response. In general, antifungal therapy should continue for at least 14 days after the last positive culture.

Esophageal candidiasis:

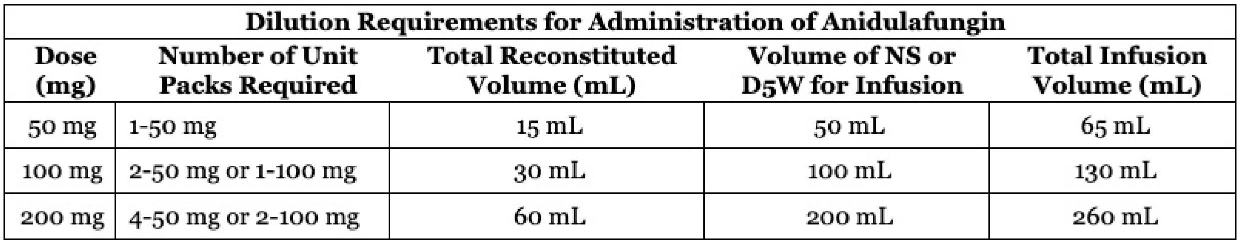
Begin with a ***loading dose*** of 100 mg as an infusion on Day 1. Follow with a daily dose of 50 mg as an infusion beginning on Day 2. Treat for a minimum of 14 days and for at least 7 days following resolution of symptoms. Relapse of esophageal candidiasis has occurred in patients with HIV infections; suppressive antifungal therapy may be considered after a course of treatment.

DOSE ADJUSTMENTS

No dose adjustment is indicated based on age, gender, or race; in patients with any degree of renal or hepatic insufficiency; or in patients using concomitant medications that are known metabolic substrates, inhibitors, or inducers of cytochrome P_{450} (CYP450) isoenzymes; see Drug/Lab Interactions. ■ No dose adjustment is required in patients with HIV who are receiving concomitant antiretroviral therapy (e.g., HIV protease inhibitors [e.g., amprenavir (Agenerase), indinavir (Crixivan), nelfinavir (Viracept), ritonavir (Norvir), saquinavir (Invirase)]).

DILUTION

Each 50-mg vial must be reconstituted with 15 mL of SWFI, and each 100-mg vial must be reconstituted with 30 mL of SWFI. The resulting concentration is 3.33 mg/mL. Aseptically transfer the reconstituted dose (50, 100, or 200 mg) into the appropriately sized IV container of D5W or NS for infusion as shown in the following chart. The final concentration of infusion solution is 0.77 mg/mL.



Dilution Requirements for Administration of Anidulafungin

Dose (mg)	Number of Unit Packs Required	Total Reconstituted Volume (mL)	Volume of NS or D5W for Infusion	Total Infusion Volume (mL)
50 mg	1-50 mg	15 mL	50 mL	65 mL
100 mg	2-50 mg or 1-100 mg	30 mL	100 mL	130 mL
200 mg	4-50 mg or 2-100 mg	60 mL	200 mL	260 mL

Filters:

No data available from manufacturer.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Excursions for 96 hours up to 25° C (77° F) are permitted, and the vial can be returned to storage at 2° to 8° C. Reconstituted solution can be stored at up to 25° C (77° F) for up to 24 hours. Infusion solution can be stored at temperatures up to 25° C for up to 48 hours or stored frozen for at least 72 hours.

COMPATIBILITY

Manufacturer states, “Do not mix or co-infuse with other medications or electrolytes. **Compatibility** of anidulafungin with intravenous substances, additives, or medications other than D5W or NS has not been established.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Flush IV line with D5W or NS before and after infusion.

Do not exceed an infusion rate of 1.1 mg/min (equivalent to 1.4 mL/min or 84 mL/hr when diluted as directed). Infusion at a rate greater than 1.1 mg/min may cause histamine-mediated reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria).

ACTIONS

A semi-synthetic lipopeptide, anidulafungin is an echinocandin, the newest class of antifungal agents. Acts by inhibiting the synthesis of 1,3-beta-D-glucan, an integral component of the fungal cell wall not present in mammalian cells. Extensively protein bound. Steady state is achieved after a loading dose. Not metabolized, it undergoes slow chemical degradation. Hepatic metabolism has not been observed. Anidulafungin is not a clinically relevant substrate, inducer, or inhibitor of cytochrome P_{450} (CYP450) isoenzymes. Terminal half-life ranges from 40 to 50 hours. Some excretion in feces, with minimal excretion in urine.

INDICATIONS AND USES

Treatment of the following fungal infections: candidemia and other forms of *Candida* infections (intra-abdominal abscess and peritonitis) and esophageal candidiasis.

Limitations of use:

Has not been studied in *Candida* infections associated with endocarditis, osteomyelitis, and meningitis. ■ Has not been studied in sufficient numbers of neutropenic patients to determine effectiveness.

CONTRAINDICATIONS

Hypersensitivity to anidulafungin or any of its components (e.g., fructose, mannitol, polysorbate 80, tartaric acid, sodium hydroxide, and/or hydrochloric acid) or to other echinocandins (e.g., micafungin [Mycamine]).

PRECAUTIONS

Do not give as an IV bolus; for IV infusion only. ■ Abnormal liver function tests have been reported. Isolated cases of significant hepatic dysfunction, hepatitis, or worsening hepatic failure have occurred. ■ *Candida* isolates with reduced susceptibility to anidulafungin have been reported, which suggests a potential for development of drug resistance. Clinical significance unknown. Cross-resistance with other echinocandins (e.g., micafungin [Mycamine]) has not been studied. ■ Has been shown to be active against *Candida albicans* resistant to fluconazole (Diflucan). ■ See Monitor and Antidote.

Monitor:

Specimens for fungal culture, serologic testing, and histopathologic testing should be obtained before therapy to isolate and identify causative organisms. Therapy may begin as soon as all specimens are obtained and before results are known. Reassess after test results are known. ■ Baseline CBC with differential and platelet count, BUN, and liver function tests (e.g., ALT, AST) may be indicated. ■ Monitor for evidence of impaired hepatic function (e.g., increased ALT, AST, serum alkaline phosphatase). ■ Monitor for S/S of infusion-related, possibly histamine-related, adverse reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria). ■ Anaphylaxis, including shock, has been reported. Monitor for S/S of a hypersensitivity reaction (e.g., bronchospasm, dyspnea, hives, hypotension, pruritus, rash, swelling of eyelids, lips, or face); discontinue infusion if a hypersensitivity reaction occurs.

Patient Education:

Promptly report any hypersensitivity or infusion-related reactions (e.g., bronchospasm, dyspnea, dizziness, flushing, itching, rash, urticaria). Report S/S of liver dysfunction (anorexia, fatigue, jaundice, nausea and vomiting, dark urine, or pale stools).

Maternal/Child:

Use during pregnancy only if benefits justify risk to fetus. Based on animal studies, anidulafungin can cause fetal harm when administered to a pregnant woman. ■ Use caution if required during breast-feeding. Secreted in milk of drug-treated rats; not known if anidulafungin is secreted in human milk. Effects on breast-fed infants or on milk production unknown. ■ Safety and effectiveness for use in pediatric patients 16 years of age or younger have not been established; however, some immunocompromised pediatric (2 through 11 years) and adolescent (12 through 17 years) patients with neutropenia were included in studies; see prescribing information.

Elderly:

Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Anidulafungin is not a clinically relevant substrate, inducer, or inhibitor of cytochrome P_{450} (CYP450) isoenzymes. It is considered unlikely that it will have a clinically relevant effect on the metabolism of drugs metabolized by CYP450 isoenzymes and/or other drugs likely to be coadministered with it.

SIDE EFFECTS

Patients treated for candidemia and other *Candida* infections:

Deep vein thrombosis; diarrhea; elevated ALT, AST, alkaline phosphatase; fever; hypokalemia; insomnia; nausea; vomiting.

Patients treated for esophageal candidiasis:

Anemia; diarrhea; dyspepsia (aggravated); elevated ALT, AST, and gamma-glutamyl transferase; fever; headache; leukopenia; nausea; neutropenia; phlebitis; rash; and vomiting.

Histamine-mediated reactions (e.g., bronchospasm, dyspnea, flushing, hypotension, pruritus, rash, urticaria) or hypersensitivity reactions (including anaphylaxis) may occur. Significant hepatic dysfunction (e.g., hepatitis, hepatocellular damage, hyperbilirubinemia, or hepatic failure) has occurred. Many other side effects have been reported in small numbers of patients.

Post-Marketing:

Anaphylactic reaction, anaphylactic shock, bronchospasm.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Reduce rate of infusion if a histamine-mediated reaction occurs. If a hypersensitivity reaction occurs, discontinue anidulafungin and treat as indicated. Appropriate treatment may include oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, IV fluids, and ventilation equipment. S/S indicative of hepatic side effects may require evaluation of benefits versus risk of continuing anidulafungin therapy. Not removed by hemodialysis. Resuscitate as indicated.

ANTHRAX IMMUNE GLOBULIN INTRAVENOUS (HUMAN) BBW

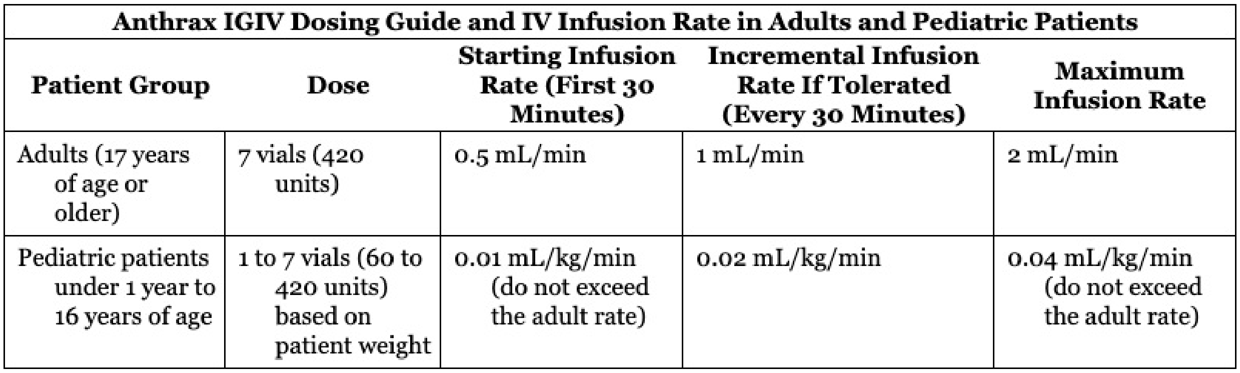
Anthrasil
Antidote
Immunizing agent (passive)

USUAL DOSE

Pretreatment:

Baseline studies required; see Monitor. See Precautions.

Used in combination with appropriate antimicrobial therapy. In adults and pediatric patients, select initial dose based on clinical severity. Data in animal models suggest that administration of higher doses may result in improved survival. In adults, severe cases may warrant the use of 14 vials (840 units). See the chart under Pediatric Dose for the number of vials recommended based on weight (1 to 7 vials) in pediatric patients.



Anthrax IGIV Dosing Guide and IV Infusion Rate in Adults and Pediatric Patients

Patient Group	Dose	Starting Infusion Rate (First 30 Minutes)	Incremental Infusion Rate If Tolerated (Every 30 Minutes)	Maximum Infusion Rate
Adults (17 years of age or older)	7 vials (420 units)	0.5 mL/min	1 mL/min	2 mL/min
Pediatric patients under 1 year to 16 years of age	1 to 7 vials (60 to 420 units) based on patient weight	0.01 mL/kg/min (do not exceed the adult rate)	0.02 mL/kg/min	0.04 mL/kg/min (do not exceed the adult rate)

PEDIATRIC DOSE

Anthrax IGIV Dosing Guide for Pediatric Patients (Based on Weight)	
Body Weight in kg	**Number of Anthrax IGIV Vials per Dose***
Less than 5 kg	1 vial
5 to less than 10 kg	1 vial
10 to less than 18 kg	2 vials
18 to less than 25 kg	3 vials
25 to less than 35 kg	4 vials
35 to less than 50 kg	5 vials
50 to less than 60 kg	6 vials
60 or more kg	7 vials

*Dose may be doubled for severe cases in patients weighing more than 5 kg.

DOSE ADJUSTMENTS

Depending on the severity of symptoms and the response to treatment, consider an initial dose of 840 units (14 vials) in adults, or double the initial recommended vials in pediatric patients. ■ Repeat dosing may be required, especially in patients experiencing substantial hemorrhage (i.e., large transfusion requirements), in patients with significant compartmental fluid losses (i.e., from large volume and/or repeated therapeutic thoracentesis and/or abdominal paracentesis), and in patients whose immune response may be impaired or delayed. Consider the magnitude of ongoing blood and fluid losses and the clinical status of the patient in determining the time interval between doses when repeat doses are administered.

DILUTION

Available frozen in single-use vials with a minimum potency of ≥60 units per vial. Bring required number of frozen vials to achieve desired dose to room temperature by one of 2 ways. (1) ***For immediate use:*** Thaw rapidly by placing at RT for 1 hour followed by a water bath at 37° C (98.6° F) until thawed; (2) ***Alternatively:*** Place vials in a refrigerator at 2° to 8° C (36° to 46° F) until thawed (approximately 14 hours). *Do not thaw in a microwave oven, and do not refreeze vials.* Set thawed vials on bench or counter for a few minutes to reach RT before preparing infusion. The solution should be clear or slightly opalescent. Gently swirl upright vials by hand to ensure uniformity. ***Do not shake***. No further dilution is required. Withdraw contents of vial(s) into a syringe, transfer into an appropriately sized IV bag, and label with the volume to be infused.

Filters:

Use of an in-line filter is optional.

Storage:

Store frozen at or below ≤−15° C (≤5° F) until required for use. Do not use after expiration date. Contains no preservatives. Prepare from vial to infusion bag and then infuse as soon as possible. Do not refreeze, reuse, or save anthrax IGIV for future use.

Discard any partially used vials.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See chart under Usual Dose. Administer in an IV line with a constant infusion pump. Slow the rate or temporarily stop the infusion if adverse reactions occur (e.g., changes in pulse rate or blood pressure, flushing, headache, nausea). For patients at risk for thrombosis, or for patients with any degree of pre-existing renal insufficiency or at risk for developing renal insufficiency, administer anthrax IGIV at the minimum infusion rate practicable; see Monitor.

ACTIONS

Anthrax immune globulin intravenous (human) is a sterile solution of purified human immune globulin G (IgG); contains polyclonal antibodies that bind the protective antigen (PA) component of *Bacillus anthracis* lethal and edema toxins. Anthrax IGIV is prepared using plasma collected from healthy, screened donors who were immunized with BioThrax (Anthrax Vaccine Adsorbed) to achieve high titers of anti-anthrax antibody, and it is purified through multiple manufacturing processes. The polyclonal immune globulin G in anthrax IGIV is a passive immunizing agent that neutralizes anthrax toxin. It binds to PA to prevent PA-mediated cellular entry of anthrax edema factor and lethal factor. Administered in combination with appropriate antibiotic therapy because it is not known to have direct antibacterial activity against anthrax bacteria, which otherwise may continue to grow and produce anthrax toxins. Peak levels are reached immediately after infusion and declined over the duration of the study (84 days). Half-life is 24 to 28 days.

INDICATIONS AND USES

Treatment of inhalational anthrax in adult and pediatric patients in combination with appropriate antibacterial drugs.

Limitations of use:

Does not have direct antibacterial activity. ■ Does not cross the blood-brain barrier and does not prevent or treat meningitis. ■ Has not been studied in the pediatric, geriatric, or obese populations.

CONTRAINDICATIONS

History of anaphylaxis or previous severe systemic reaction associated with administration of anthrax IGIV or other human immune globulin preparations. ■ IgA-deficient patients with antibodies against IgA and a history of IgA hypersensitivity.

PRECAUTIONS

For intravenous use only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Repeated dosing and single doses greater than 840 units have not been studied in humans. Without substantially delaying therapy, if doses greater than initial recommendations or repeat doses are required, consider performing therapeutic thoracentesis and/or abdominal paracentesis as indicated before or concurrently with administration of anthrax IGIV. ■ Hypersensitivity reactions, including anaphylaxis, may occur. Patients with known antibodies to IgA may be at greater risk; see Contraindications. ■ Contains maltose; may give falsely high blood glucose levels with some point-of-care blood glucose testing systems (e.g., those based on the GDH-PQQ or glucose-dye-oxidoreductase methods), resulting in inappropriate administration of insulin and life-threatening hypoglycemia; see Monitor. ■ Thrombosis may occur with immune globulin products, including anthrax IGIV. Risk factors may include advanced age, cardiovascular risk factors, history of venous or arterial thrombosis, hypercoagulable conditions, hyperviscosity, indwelling vascular catheters, prolonged immobilization, and the use of estrogens. Thrombosis may occur in the absence of known risk factors. Consider risk versus benefit against alternative therapies if anthrax IGIV administration is being considered. ■ Acute renal dysfunction, acute renal failure, acute tubular necrosis, proximal tubular nephropathy, osmotic nephropathy, and death may occur with IGIV products, including anthrax IGIV. Use with caution in patients with any degree of pre-existing renal insufficiency and in patients at risk for developing renal insufficiency (e.g., patients receiving known nephrotoxic drugs, patients with diabetes, age greater than 65 years, paraproteinemia, sepsis, volume depletion). ■ Infusion-related reactions may occur. May be related to the rate of infusion. ■ Hemolytic anemia and hemolysis may develop subsequent to anthrax IGIV administration. Risk factors may include high doses (e.g., greater than 2 Gm per kg) as a single dose or divided over several days, non-O blood group, or an underlying inflammatory state (e.g., elevated C-reactive protein or erythrocyte sedimentation rate). ■ Aseptic meningitis syndrome (AMS) may occur with IGIV products, including anthrax IGIV. Usually associated with high total doses (e.g., greater than 2 Gm per kg). May begin within hours to 2 days after treatment but improves within several days after discontinuing treatment. ■ Noncardiogenic pulmonary edema may occur in patients receiving IGIV products, including anthrax IGIV. ■ Made from human plasma; may carry a risk of transmitting blood-borne infectious agents (e.g., viruses, Creutzfeldt-Jakob disease). No cases of transmission of these infections have been reported.

Monitor:

Obtain baseline renal function tests (e.g., BUN, serum creatinine) before the initial infusion of anthrax IGIV, and repeat at appropriate intervals. Monitor urine output. ■ Monitor for S/S of a hypersensitivity reaction (e.g., angioedema, bronchospasm with wheezing or cough, erythema, hypotension, laryngeal edema, pruritus, rash, stridor, tachycardia, tightness of the chest, urticaria). ■ To avoid interference by maltose contained in anthrax IGIV, perform blood glucose measurement in patients receiving anthrax IGIV with a glucose-specific method (monitor and test strips). Review product information and, if uncertainty exists, contact the manufacturer to confirm appropriateness for use with maltose-containing products. ■ Monitor for S/S of thromboembolic complications (e.g., chest pain, limb or abdominal swelling and/or pain, shortness of breath, loss of sensation or motor power, altered consciousness, vision, or speech). For patients at risk for thrombosis, administer anthrax IGIV at the minimum infusion rate practicable. Ensure adequate hydration before administration, and assess blood viscosity in patients at risk for hyperviscosity. ■ Consider baseline assessment of blood viscosity in patients at risk for hyperviscosity, including those with cryoglobulins, fasting chylomicronemia/markedly high triacylglycerols (triglycerides), or monoclonal gammopathies. ■ For patients with any degree of pre-existing renal insufficiency and in patients at risk for developing renal insufficiency, administer anthrax IGIV at the minimum rate of infusion practicable. Ensure that patients are not volume depleted before anthrax IGIV infusion. Do not exceed the recommended infusion rate, and follow the infusion schedule closely. ■ Monitor for infusion-related reactions (e.g., chills, fever, headache, nausea and vomiting) during and after the infusion and follow the recommended infusion rate. ■ Monitor for S/S of hemolysis. In higher-risk patients, consider appropriate lab testing (e.g., hemoglobin or hematocrit) before infusion; repeat in 36 to 96 hours and again 7 to 10 days after infusion. ■ Monitor for S/S of AMS (e.g., drowsiness, fever, nausea and vomiting, nuchal rigidity, painful eye movements, photophobia, and severe headache). CSF studies are frequently positive with pleocytosis, (predominantly from the granulocytic series) and with elevated protein levels, but negative culture results. ■ Monitor for S/S of transfusion-related acute lung injury (TRALI) such as fever, hypoxia, normal left ventricular function, pulmonary edema, severe respiratory distress. Typically occurs within 1 to 6 hours after the infusion. If TRALI is suspected, perform appropriate tests for the presence of anti-HLA and antineutrophil antibodies in the product.

Patient Education:

Read FDA-approved patient labeling. ■ Inform health care provider if you have had previous reactions to human immune globulin or are IgA deficient. ■ Promptly report chills and/or fever and other S/S of an infusion or hypersensitivity reaction (e.g., chest pain, dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, rash, shortness of breath). ■ May interfere with some types of blood glucose monitoring systems. ■ There is a potential risk for serious adverse effects from administration of immune globulin products, including thrombosis, hemolysis, AMS, TRALI, ARDS, and acute renal failure. Report a burning sensation in the head, chills, cyanosis, diaphoresis, dyspnea, faintness or light-headedness, fatigue, fever, hives, itching or rash, neck pain or difficulty moving neck, tachycardia, wheezing. Report chest pain or tightness, pain and/or swelling of an arm or a leg with warmth over the affected area, difficulty passing urine, decreased urine output, fluid retention, edema, shortness of breath, or sudden weight gain. Remote risk of viral or Creutzfeldt-Jakob disease infection; consider risk versus benefit of therapy.

Maternal/Child:

No human data to assess the risk for anthrax IGIV during pregnancy or breast-feeding. Use only if clearly needed. ■ Safety and effectiveness for use in pediatric patients have not been studied but may be used. Dose is based on body weight.

Elderly:

Safety and effectiveness in patients over 65 years of age have not been studied.

DRUG/LAB INTERACTIONS

IGIV may impair the effectiveness of **live virus vaccines**. Defer vaccination with live virus vaccines until approximately 3 months after anthrax IGIV administration. Revaccinate patients who received anthrax IGIV shortly after a live virus vaccination. ■ Based on animal studies, anthrax IGIV did not interfere with antibiotic therapy (e.g., ciprofloxacin [Cipro], levofloxacin [Levaquin]). ■ May give **falsely high blood glucose levels** with certain types of blood glucose testing systems; see Precautions. ■ May **interfere with some serologic tests** (e.g., a false-positive Coombs' test). ■ **Elevated glucose** may be reported in urinalysis specimens.

SIDE EFFECTS

Back pain, headache, infusion site pain and swelling, and nausea were most common in healthy volunteers in clinical trials. Safety profile may be different in patients with severe inhalational/systemic anthrax. Serious adverse reactions are hypersensitivity reactions, including anaphylaxis and thrombosis. Infusion reactions may occur. Acute renal insufficiency/failure, acute respiratory distress syndrome, ascites, cardiac arrest/death, coagulopathy, edema, hyperkalemia, hypotension, metabolic acidosis, peripheral edema, pleural effusion, and pulmonary edema have been reported. Other serious side effects associated with IGIV products may occur.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically or by decreasing the rate of infusion. Toxicity from anthrax and/or serious adverse reactions may be life threatening. Supportive and/or aggressive therapy as indicated will help sustain the patient. If renal function deteriorates, consider discontinuing anthrax IGIV. Discontinue treatment if AMS occurs. If a hypersensitivity reaction occurs, discontinue anthrax IGIV and treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol (Ventolin), IV fluids, and ventilation equipment as indicated. Manage TRALI using oxygen therapy with adequate ventilator support. Resuscitate as necessary.

ANIFROLUMAB

(an-i-**FROL**-ue-mab)
Saphnelo
Immune globulin
Interferon receptor antagonist

USUAL DOSE

Adult:

300 mg IV every 4 weeks.

PEDIATRIC DOSE

Safety and efficacy have not been established.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

DILUTION

Before use, inspect vial and do not use if solution is cloudy, discolored, or contains particulate matter. Allow to warm to room temperature. ***Do not shake vial.*** Withdraw and discard 2 mL of NS from a 100-mL bag; withdraw 2 mL from the vial and add to the NS bag. Invert bag and mix gently; ***do not shake***.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS.

RATE OF ADMINISTRATION

Use a separate line with an in-line, low–protein binding, 0.2-micron filter and infuse over 30 minutes. Upon completion, flush infusion set with 25 mL of NS.

ACTIONS

Anifrolumab is an IgG1-kappa monoclonal antibody that blocks the activity of type 1 interferon receptors, which in turn reduces inflammatory and immunologic processes associated with systemic lupus erythematosus.

INDICATIONS AND USES

Systemic lupus erythematosus.

CONTRAINDICATIONS

Anaphylaxis to anifrolumab or any component of the formulation.

PRECAUTIONS

Infusion reactions:

Consider premedication in patients with a history of infusion reactions. Stop infusion and start supportive treatment if patient develops infusion-related reactions.

Infections:

Serious and potentially fatal infections may occur during treatment. Patients are at increased risk for respiratory infections and herpes zoster.

Malignancy:

Immunosuppressant therapy may increase the risk of malignancy.

Immunizations:

Patients should be brought up-to-date with immunizations before starting therapy. Do not give live or live attenuated vaccines.

Monitor:

Monitor for signs and symptoms of hypersensitivity and infection.

Patient Education:

Contact physician for infection (fever, chills, sore throat, ear, sinus pain, cough, increased sputum or change in color of sputum, painful urination, mouth sores or wounds that do not heal); stomach pain or diarrhea; warm, red, or painful skin or sores on body; muscle pain; sweating; shingles; dizziness; headache; vomiting; fatigue; weakness.

Maternal/Child:

Anifrolumab is a humanized monoclonal antibody (IgG1), and human IgG is known to cross the placenta. Data collection to monitor pregnancy and infant outcomes is ongoing. It is unknown whether anifrolumab will pass in breast milk; the manufacturer states the decision to breast-feed during therapy should consider the risk of infant exposure.

Elderly:

Refer to adult dosing and precautions.

DRUG/LAB INTERACTIONS

There are many drug interactions with anifrolumab, and the following drugs should be avoided: bacilli Calmette-Guérin (BCG), baricitinib, belimumab, biologic antipsoriasis agents, biologic disease-modifying antirheumatic drugs, cladribine, dengue tetravalent vaccine, MMR and varicella virus vaccine, natalizumab, pimecrolimus, poliovirus vaccine, ruxolitinib, tacrolimus topical, talimogene laherparepvec, tertomotide, tofacitinib, typhoid vaccine, upadacitinib, vaccines (live), yellow fever vaccine.

SIDE EFFECTS

Infection, bronchitis, upper respiratory tract infection, malignant neoplasm of breast, squamous cell carcinoma, hypersensitivity reaction, antibody development, herpes zoster infection, cough, infusion-related reactions, anaphylaxis, angioedema.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions.

ANTIHEMOPHILIC FACTOR (HUMAN ■

RECOMBINANT ■ RECOMBINANT [Fc FUSION PROTEIN] ■ RECOMBINANT [PEGYLATED] ■ RECOMBINANT [PEGYLATED-aucl] ■ RECOMBINANT [SINGLE CHAIN] ■ RECOMBINANT [PORCINE SEQUENCE][a])

(an-tie-hee-moe-**FIL**-ik **FAK**-tor)

AHF, Factor VIII ■ Hemofil M, Koate DVI ■ Advate, Helixate FS, Kogenate FS, Kogenate FS Bio-Set, Kovaltry, Kovaltry Bio-Set, Novoeight, Nuwiq, Recombinate, Xyntha, Xyntha Solofuse ■ Eloctate ■ Adynovate ■ Jivi ■ Afstyla ■ Obizur[a]

Antihemophilic agent

Available factor VIII products and their origins include the following:

Hemofil M, Koate DVI (Human):

Blood product derivatives. May contain trace amounts of mouse or hamster protein.

Advate, Helixate FS, Kogenate FS, Kogenate FS Bio-Set, Kovaltry, Kovaltry Bio-Set, Novoeight, Xyntha, Xyntha Solofuse (Recombinant):

Stabilized without human albumin. No human or animal-derived proteins are used in the purification or formulation processes. May contain trace amounts of mouse or hamster protein.

Recombinate (Recombinant):

Stabilized in human albumin. May contain bovine protein and trace amounts of mouse or hamster protein.

Eloctate (Recombinant):

B-domain–deleted recombinant factor VIII Fc (BDD-rFVIIIFc) fusion protein is the active ingredient. No human or animal-derived proteins are used in the purification or formulation processes.

Nuwiq (Recombinant):

B-domain–deleted recombinant factor VIII (BDD-rFVIII) is the active ingredient. No human or animal-derived proteins are used in the purification or formulation processes.

Adynovate (Recombinant) PEGylated:

The cell culture, pegylation, purification process, and formulation do not use additives of human or animal origins. May contain trace amounts of hamster protein.

Jivi (Recombinant) PEGylated-aucl:

The cell culture, pegylation, purification process, and formulation do not use additives of human or animal origins. May contain trace amounts of mouse and hamster protein.

Afstyla (Recombinant):

A single polypeptide chain with a truncated B-domain. No human or animal-derived proteins are used in the purification or formulation processes.

Obizur* (Recombinant):

Porcine sequence. May contain trace amounts of hamster protein.

Alphanate and Humate P (see AHF and von Willebrand Factor Complex monograph):

From human plasma; intermediate and high purity.

USUAL DOSE (International units [IU])

Pretreatment:

Pretesting and baseline studies required; see Monitor.

Adults and pediatric patients:

Dosing is completely individualized. Dose, frequency, and duration of treatment are based on severity of the factor VIII deficiency, location and extent of bleeding, clinical condition of the patient, desired antihemophilic factor level, body weight, and presence of factor VIII inhibitors. Measure factor VIII level before administration; see Monitor. In general, a dose of 1 IU/kg will raise the plasma factor VIII activity by 2 IU/dL. On average, a plasma antihemophilic factor level of 20% to 40% of normal is required to control minor hemorrhage. A level of 30% to 60% of normal may be required to control moderate bleeding; greater percentages are required for major bleeding or surgical procedures.

All products except Obizur use a variation of the following formula.

To calculate the dose needed based on a desired factor VIII increase (%):

$$\text{Dose (IU)} = \text{Body weight (kg)} \times \text{Desired factor VIII increase (IU/dL or \% of normal)} \times 0.5$$

To calculate the expected % factor VIII increase for a given dose:

$$\text{Expected \% factor VIII increase} = (\text{\# Units administered} \times 2) \div \text{Body weight (kg)}$$

The following charts outline AHF dosing recommendations for the various AHF products. ***Consult individual product labeling for more detailed information.***

Control and Prevention of Bleeding Episodes				
Degree of Bleeding	**AHF Product**	**Required Peak Postinfusion Factor VIII Activity (as % of Normal or IU/dL)**	**Dose (IU/kg)**	**Frequency and Duration of Therapy**
Minor Early hemarthrosis, mild muscle bleed, or mild oral bleed Superficial muscle or soft tissue and oral bleeds	Advate	20 to 40	10 to 20 IU/kg	Repeat every 12 to 24 hr (8 to 24 hr in patients under 6 years of age) for 1 to 3 days until bleeding is resolved or healing is achieved.
	Adynovate Jivi[a]	20 to 40	10 to 20 IU/kg	Adynovate: Repeat every 12 to 24 hr until bleeding is resolved. Jivi: Repeat every 24 to 48 hr until bleeding is resolved.
	Afstyla	20 to 40	See formula	Repeat every 12 to 24 hr until bleeding is resolved.
	Eloctate	40 to 60	20 to 30 IU/kg	Repeat every 24 to 48 hr (12 to 24 hr in patients under 6 years of age) until bleeding is resolved or healing is achieved.
	Helixate FS Kogenate FS	20 to 40	10 to 20 IU/kg	Repeat dose if there is evidence of further bleeding until bleeding is resolved.
	Koate DVI	20	10 IU/kg	May respond to a single dose. Repeat if there is evidence of further bleeding.
	Kovaltry Kovaltry Bio-Set	20 to 40	See formula	Repeat every 12 to 24 hr for at least 1 day until bleeding episode as indicated by pain is resolved or healing is achieved.
	Novoeight Recombinate Xyntha Hemofil M	20 to 40	See formula	Repeat every 12 to 24 hr for at least 1 day (usually 1 to 3 days) until bleeding is resolved or healing is achieved.
	Nuwiq	20 to 40	See formula	Repeat every 12 to 24 hr for at least 1 day until bleeding is resolved.
Moderate Moderate bleeding into muscle (except iliopsoas), bleeding into oral cavity, definite hemarthroses, and known trauma	Advate	30 to 60	15 to 30 IU/kg	Repeat every 12 to 24 hr (8 to 24 hr in patients under 6 years of age) for 3 days or more until bleeding is resolved or healing is achieved.

	Adynovate Jivi[a]	30 to 60	15 to 30 IU/kg	Adynovate: Repeat every 12 to 24 hr until bleeding is resolved. Jivi: Repeat every 24 to 48 hr until bleeding is resolved.
	Afstyla	30 to 60	See formula	Repeat every 12 to 24 hr until bleeding is resolved.
	Eloctate	40 to 60	20 to 30 IU/kg	Repeat every 24 to 48 hr (12 to 24 hr in patients under 6 years of age) until bleeding is resolved or healing is achieved.
	Helixate FS Kogenate FS	30 to 60	15 to 30 IU/kg	Repeat every 12 to 24 hr until bleeding is resolved.
	Koate DVI	30 to 50	Initial: 15 to 25 IU/kg Repeat: 10 to 15 IU/kg	Repeat with lower dose every 8 to 12 hr if needed until bleeding is resolved or healing is achieved.
	Kovaltry Kovaltry Bio-Set	30 to 60	See formula	Repeat every 12 to 24 hr for 3 to 4 days or more until pain and acute disability are resolved.
	Novoeight Recombinate Xyntha Hemofil M	30 to 60	See formula	Repeat every 12 to 24 hr until pain and acute disability are resolved and/or adequate local hemostasis is achieved (approximately 3 to 4 days).
	Nuwiq	30 to 60	See formula	Repeat every 12 to 24 hr for 3 to 4 days or more until bleeding is resolved.
Major/Life Threatening Significant GI bleed; intracranial, intraabdominal, or intrathoracic bleeding; CNS bleeding; limb-threatening hemorrhage; bleeding into retropharyngeal or retroperitoneal spaces or iliopsoas sheath or into eyes/retina; fractures; head trauma	Advate	60 to 100	30 to 50 IU/kg	Repeat every 8 to 24 hr (6 to 12 hr in patients under 6 years of age) for 3 days or more until bleeding is resolved or healing is achieved.
	Adynovate Jivi[a]	60 to 100	30 to 50 IU/kg	Every 8 to 12 hr until bleeding is resolved.
	Afstyla	60 to 100	See formula	Repeat every 8 to 24 hr until bleeding is resolved.

Eloctate	80 to 100	40 to 50 IU/kg	Repeat every 12 to 24 hr (8 to 24 hr in patients under 6 years of age) until bleeding is resolved or healing is achieved (approximately 7 to 10 days).
Helixate FS Kogenate FS	80 to 100	Initial: 40 to 50 IU/kg Repeat: 20 to 25 IU/kg	Every 8 to 12 hr until bleeding is resolved.
Koate DVI	80 to 100	Initial: 40 to 50 IU/kg Repeat: 20 to 25 IU/kg	Every 8 to 12 hr until bleeding is resolved.
Kovaltry Kovaltry Bio-Set	60 to 100	See formula	Repeat every 8 to 24 hr until bleeding is resolved.
Novoeight Recombinate Xyntha Hemofil M	60 to 100	See formula	Repeat every 8 to 24 hr until bleeding is resolved (approximately 7 to 10 days).
Nuwiq	60 to 100	See formula	Repeat every 8 to 24 hr until bleeding is resolved.

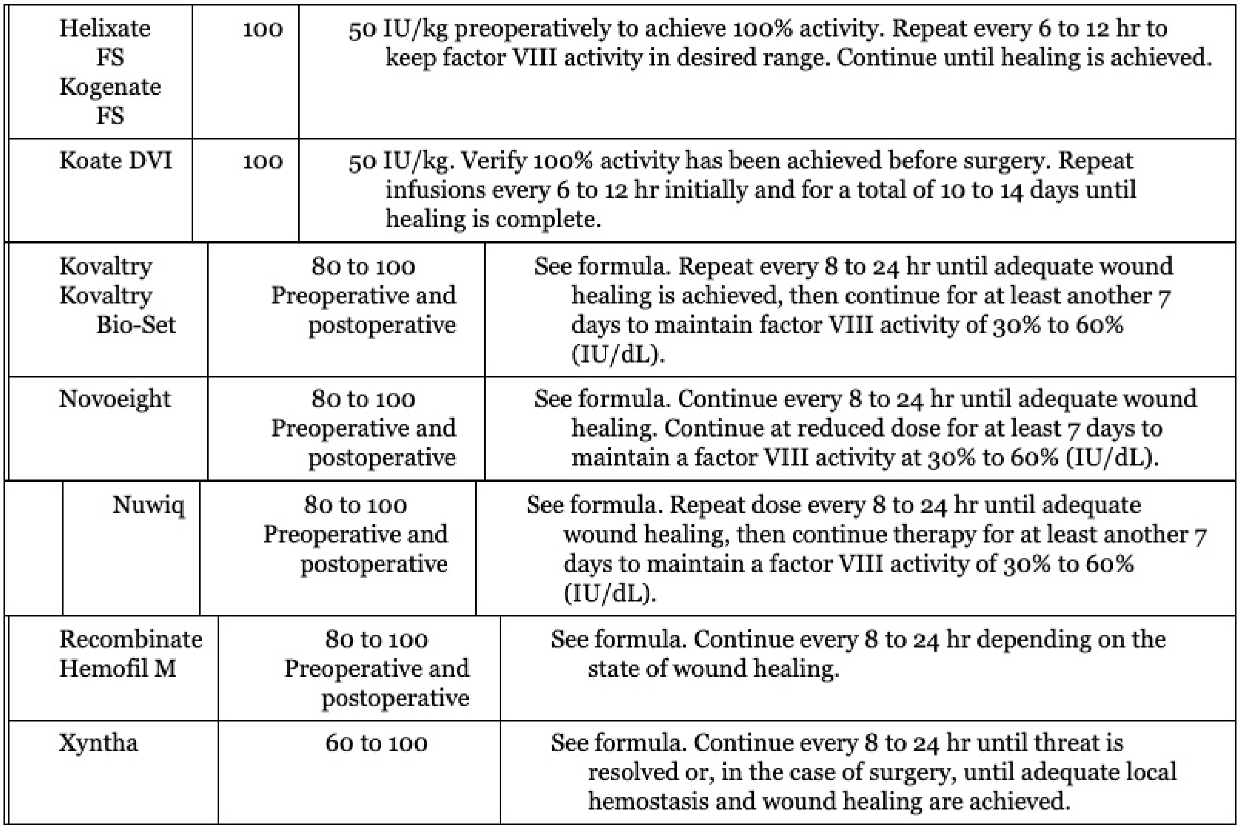
IU, International unit.

[a] Jivi: Total recommended maximum dose per infusion is approximately 6,000 IU (rounded to vial size).

Perioperative Management (Surgical Prophylaxis)

Type of Surgery	AHF Product	Required Peak Postinfusion Factor VIII Activity (as % of Normal or IU/dL)	Dose, Frequency, and Duration of Therapy
Minor Including tooth extraction	Advate	60 to 100	A single bolus infusion (30 to 50 IU/kg) beginning within 1 hr of operation. Optional additional dosing every 12 to 24 hr as needed to control bleeding. For dental procedures, adjunctive therapy may be considered.
	Adynovate	60 to 100	A single bolus infusion (30 to 50 IU/kg) beginning within 1 hr of operation. Repeat after 24 hours if necessary. Single dose or repeat as needed until bleeding is resolved.
	Afstyla	30 to 60	See formula. Repeat every 24 hr for at least 1 day until healing is achieved.
	Eloctate	50 to 80	25 to 40 IU/kg. Repeat every 24 hr (12 to 24 hr in patients under 6 years of age). Continue for at least 1 day until healing is achieved.

	Jivi[a]	30 to 60 Preoperative and postoperative	15 to 30 IU/kg. Repeat every 24 hr for at least 1 day until healing is achieved.
	Helixate FS Kogenate FS	30 to 60	15 to 30 IU/kg. Repeat every 12 to 24 hr until bleeding is resolved.
	Koate DVI	Not listed	See Major. Less intensive treatment schedules may provide adequate hemostasis.
	Kovaltry Kovaltry Bio-Set	30 to 60 Preoperative and postoperative	See formula. Repeat every 24 hr for at least 1 day until healing is achieved.
	Novoeight	30 to 60	See formula. Repeat every 24 hr for at least 1 day until healing is achieved.
	Nuwiq	30 to 60 Preoperative and postoperative	See formula. Repeat dose every 24 hr. Continue at least 1 day until healing is achieved.
	Recombinate Hemofil M	60 to 80	See formula. A single infusion plus oral antifibrinolytic therapy within 1 hr is sufficient in approximately 70% of cases.
	Xyntha	30 to 60	See formula. Repeat every 12 to 24 hr for 3 to 4 days until adequate local hemostasis is achieved. For tooth extraction, a single infusion plus oral antifibrinolytic therapy within 1 hr may be sufficient.
Major Examples include intracranial, intra-abdominal, or intrathoracic surgery, joint replacement surgery	Advate Adynovate	80 to 120 Preoperative and postoperative	Preoperative: 40 to 60 IU/kg. Verify 100% activity has been achieved before surgery. Maintenance: 40 to 60 IU/kg every 8 to 24 hr (6 to 24 hr in patients under 6 years of age [Advate] or under 12 years of age [Adynovate]) depending on desired level of factor VIII and state of wound healing.
	Afstyla	80 to 100	See formula. Repeat every 8 to 24 hr until adequate wound healing, then continue for at least another 7 days to maintain a factor VIII activity of 30% to 60% (IU/dL).
	Eloctate	80 to 120 Preoperative and postoperative	Preoperative: 40 to 60 IU/kg. Verify 100% activity has been achieved before surgery. Follow with a repeat dose of 40 to 50 IU/kg after 8 to 24 hr (6 to 24 hr in patients under 6 years of age) and then every 24 hr to maintain factor VIII activity within target range until adequate wound healing; then continue for at least 7 days to maintain factor VIII activity within target range.
	Jivi[a]	80 to 100 Preoperative and postoperative	40 to 50 IU/kg. Repeat every 12 to 24 hours until adequate wound healing is complete, then continue therapy for at least another 7 days to maintain a Factor VIII activity of 30% to 60% (IU/dL).



Helixate FS Kogenate FS	100	50 IU/kg preoperatively to achieve 100% activity. Repeat every 6 to 12 hr to keep factor VIII activity in desired range. Continue until healing is achieved.
Koate DVI	100	50 IU/kg. Verify 100% activity has been achieved before surgery. Repeat infusions every 6 to 12 hr initially and for a total of 10 to 14 days until healing is complete.
Kovaltry Kovaltry Bio-Set	80 to 100 Preoperative and postoperative	See formula. Repeat every 8 to 24 hr until adequate wound healing is achieved, then continue for at least another 7 days to maintain factor VIII activity of 30% to 60% (IU/dL).
Novoeight	80 to 100 Preoperative and postoperative	See formula. Continue every 8 to 24 hr until adequate wound healing. Continue at reduced dose for at least 7 days to maintain a factor VIII activity at 30% to 60% (IU/dL).
Nuwiq	80 to 100 Preoperative and postoperative	See formula. Repeat dose every 8 to 24 hr until adequate wound healing, then continue therapy for at least another 7 days to maintain a factor VIII activity of 30% to 60% (IU/dL).
Recombinate Hemofil M	80 to 100 Preoperative and postoperative	See formula. Continue every 8 to 24 hr depending on the state of wound healing.
Xyntha	60 to 100	See formula. Continue every 8 to 24 hr until threat is resolved or, in the case of surgery, until adequate local hemostasis and wound healing are achieved.

IU, International unit.

[a] Jivi: Total recommended maximum dose per infusion is approximately 6,000 IU (rounded to vial size).

Obizur (porcine preparation):

Obizur does not use a formula. **Indicated for use only in acquired hemophilia. Not indicated for use in congenital hemophilia A**. The recommended dose of Obizur for minor, moderate, and/or major bleeding is 200 IU/kg as an initial dose. Subsequent doses may be given every 4 to 12 hours and should be titrated to individual clinical response and to maintain recommended factor VIII trough levels (50% to 100% of normal for minor or moderate bleeding and 100% to 200% of normal for an acute bleed, decreasing to 50% to 100% of normal after acute bleed is controlled, if required). Maintain the factor VIII activity within the target range. Plasma levels of factor VIII should not exceed 200% of normal or 200 IU/dL.

Routine prophylaxis to prevent or reduce the frequency of bleeding

(e.g., severe factor VIII deficiency with frequent hemorrhages):

Advate:

20 to 40 IU/kg every other day (3 to 4 times per week). Alternately, an every-third-day dosing regimen targeted to maintain factor VIII trough levels greater than or equal to 1% may be used. Adjust dose based on patient response.

Adynovate:

Adults and adolescents (12 years of age or older): Administer 40 to 50 IU/kg 2 times per week. ***Pediatric patients (under 12 years of age):*** 55 IU/kg 2 times per week with a maximum of 70 IU/kg/dose. Adjust dose based on patient's clinical response.

Afstyla:

Adults and adolescents (12 years of age or older): Recommended starting regimen is 20 to 50 IU/kg administered 2 to 3 times weekly. ***Pediatric patients (under 12 years of age):*** Recommended starting regimen is 30 to 50 IU/kg administered 2 to 3 times weekly. More frequent or higher doses may be required in pediatric patients under 12 years of age to account for the higher clearance in this age-group. Adjust dose based on patient's response.

Eloctate:

Initiate therapy with a dose of 50 IU/kg every 4 days. Adjust dose based on patient response (range 25 to 65 IU/kg at 3- to 5-day intervals). More frequent or higher doses up to 80 IU/kg may be required in pediatric patients under 6 years of age.

Jivi:

Initiate therapy at 30 to 40 IU/kg twice weekly. Based on bleeding episodes, the regimen may be adjusted to 45 to 60 IU/kg every 5 days. Regimen may be further individually adjusted to less or more frequent dosing. Total recommended maximum dose per infusion is approximately 6,000 IU (rounded to vial size).

Helixate FS and Kogenate FS:

Adults: 25 IU/kg 3 times a week. ***Pediatric patients:*** 25 IU/kg every other day.

Kovaltry, Kovaltry Bio-Set:

Adults and adolescents: 20 to 40 IU/kg 2 or 3 times a week. ***Pediatric patients 12 years of age or younger:*** 25 to 50 IU/kg twice weekly, 3 times weekly, or every other day according to individual requirements.

Novoeight:

Adults and adolescents (12 years of age or older): 20 to 50 IU/kg 3 times a week or 20 to 40 IU/kg every other day. ***Pediatric patients (under 12 years of age):*** 25 to 60 IU/kg 3 times a week or 25 to 50 IU/kg every other day.

Nuwiq:

Adults and adolescents (12 to 17 years of age): 30 to 40 IU/kg every other day. ***Pediatric patients (2 to 11 years of age):*** 30 to 50 IU/kg every other day or 3 times per week.

DOSE ADJUSTMENTS

Titrate the dose and frequency to the patient's clinical response. ■ If factor VIII level fails to increase as expected or if bleeding is not controlled after administration of the calculated dose, factor VIII antibodies (inhibitors) are probable; may respond to an increased dose, especially if titer is less than 10 Bethesda units/mL. Frequent determinations of circulating AHF levels indicated. ■ Higher or more frequent dosing may be required in pediatric patients.

DILUTION

Products are available in multiple strengths. Actual number of AHF units is shown on each vial. Consult package insert of product to obtain product-specific information on dilution. All preparations provide diluent, and most provide administration equipment that may include transfer devices, needles (single- or double-ended), filters or filter needles, syringes, vial adapters, and/or administration sets for each vial. Use only the diluent provided, and maintain strict aseptic technique. Warm to room temperature (25° C [77° F]) before dilution and maintain throughout administration to avoid precipitation of active ingredients. If more than one vial is required to achieve the desired dose, multiple vials may be drawn into the same container (e.g., syringe). Follow manufacturer's instructions. Products do not contain a preservative, and all products must be used within 3 hours of reconstitution (4 hours for Afstyla and Novoeight).

Filters:

Supplied by manufacturer if required.

Storage:

Consult package insert of product to obtain product-specific information on storage requirements after reconstitution. Before reconstitution, store all formulations in original packages to protect from light at 2° to 8° C (35° to 46° F). (Recombinate may be stored at RT or under refrigeration.) Do not freeze. **All formulations except Adynovate and Obizur** can be stored at RT for 2 months or longer before reconstitution. **Adynovate** can be stored at RT for up to 1 month. Do not return to the refrigerator after storage at RT. **Afstyla** can be stored at RT, not to exceed 25° C (77° F), for a single period of up to 3 months (within the expiration date on carton and vial labels). Do not return product to the refrigerator. **Jivi** can be stored at RT for up to 6 months. Do not return to the refrigerator after storage at RT. **Obizur** should be refrigerated until use. Do not use beyond expiration dates on vials (or revised expiration date if stored at RT, whichever is earlier).

COMPATIBILITY

Administration through a separate line without mixing with other IV fluids or medications is recommended.

RATE OF ADMINISTRATION

Use administration set supplied by manufacturer, if provided. Rate of administration is based on patient comfort. Reduce rate of infusion or temporarily discontinue if there is a significant increase in heart rate or if S/S of hypersensitivity occur.

Advate, Adynovate:
A single dose over 5 minutes or less. Do not exceed a rate of 10 mL/min.

Afstyla, Eloctate, Hemofil M:
A single dose administered at a rate not to exceed 10 mL/min.

Jivi:
A single dose administered over 1 to 15 minutes. Maximum infusion rate is 2.5 mL/min.

Helixate FS, Kogenate FS, Kogenate FS Bio-Set, Kovaltry, Kovaltry Bio-Set:
A single dose over 1 to 15 minutes is usually well tolerated.

Koate-DVI:
A single dose over 5 to 10 minutes.

Novoeight:
A single dose over 2 to 5 minutes.

Nuwiq:
A single dose at a maximum rate of 4 mL/min.

Obizur:
A single dose at a rate of 1 to 2 mL/min.

Recombinate (reconstituted with 5 mL of SWFI):
Do not exceed a rate of 5 mL/min.

Recombinate (reconstituted with 10 mL SWFI):
Do not exceed a rate of 10 mL/min.

Xyntha, Xyntha Solofuse:
A single dose over several minutes, based on patient comfort.

ACTIONS

AHF is one of nine major factors in the blood that must act in sequence to produce coagulation, or clotting. It is the specific clotting factor deficient in patients with hemophilia A (classic hemophilia). Administration of AHF can temporarily correct the coagulation defect in these patients. One international unit (IU) of AHF is approximately equal to the level of factor VIII activity in 1 mL of fresh pooled human plasma. **Adynovate** and **Jivi** exhibit an extended terminal half-life through pegylation, which reduces binding to the physiologic factor VIII clearance receptor (LRP1). **Afstyla** is expressed as a single-chain factor VIII molecule with covalent linkage between heavy and light chains, keeping the molecule in the single-chain form and resulting in increased stability and increased von Willebrand factor (vWF) affinity. vWF stabilizes factor VIII and protects it from degradation.

Recombinant porcine sequence AHF (Obizur):

Patients with acquired hemophilia have normal factor VIII genes but develop autoantibodies against their own factor VIII (i.e., inhibitors). These autoantibodies neutralize circulating human factor VIII and create a functional deficiency of factor VIII. Obizur temporarily replaces the inhibited endogenous factor VIII that is needed for effective hemostasis in patients with acquired hemophilia A.

INDICATIONS AND USES

On-demand treatment and control of bleeding episodes in adults and pediatric patients with hemophilia A (congenital factor VIII deficiency) **(all products *except*** Jivi and Obizur). ■ Perioperative management (surgical prophylaxis) in adults and pediatric patients with hemophilia A **(all products *except*** Jivi and Obizur). ■ Routine prophylaxis to prevent or reduce the frequency of bleeding in adults and pediatric patients with hemophilia A **(Advate, Adynovate, Afstyla, Eloctate, Helixate FS, Kogenate FS, Kovaltry, Kovaltry Bio-Set, Novoeight, Nuwiq).** ■ Routine prophylaxis to prevent bleeding episodes and risk of joint damage in pediatric patients without pre-existing joint damage **(Helixate FS, Kogenate FS)**. ■ On-demand treatment and control of bleeding episodes, perioperative management of bleeding, and routine prophylaxis to reduce the frequency of bleeding episodes in adolescent and adult patients (12 years and older) with hemophilia A **(Jivi)**. ■ Treatment of bleeding episodes in adults with ***acquired hemophilia A (Obizur)***.

Limitations of use:

All products: Not indicated for treatment of von Willebrand disease.

Jivi:

Jivi is not indicated for use in pediatric patients under 12 years of age due to greater risk for hypersensitivity reactions. ■ **Jivi** is not indicated for use in previously untreated patients.

Obizur:

Safety and efficacy of **Obizur** has not been established in patients with a baseline anti-porcine factor VIII inhibitor titer of greater than 20 Bethesda units. ■ **Obizur is not indicated for treatment of congenital hemophilia A.**

CONTRAINDICATIONS

All products:

Hypersensitivity to the specific product or to any component of a product (e.g., mouse, hamster, or bovine protein [monoclonal antibody–derived factor VIII, porcine sequence]; various stabilizers; polysorbate 80; polyethylene glycol [PEG]).

PRECAUTIONS

Should be administered under the direction of a physician specialist. ■ Hypersensitivity reactions (including anaphylaxis) are possible. ■ Formation of neutralizing antibodies (inhibitors) to factor VIII can occur; see Monitor. ■ In patients receiving **Jivi**, a clinical immune response associated with IgM anti-PEG antibodies (manifested as symptoms of acute hypersensitivity and/or loss of drug effect) has been observed, primarily in patients under 6 years of age. Symptoms of the clinical immune response were transient, and anti-PEG IgM titers decreased over time to undetectable levels. In cases of clinical suspicion of loss of drug effect, conduct testing for Factor VIII inhibitors. A low post-infusion Factor VIII level in the absence of detectable Factor VIII inhibitors indicates that loss of drug effect is likely due to anti-PEG antibodies. Discontinue **Jivi** and switch patient to a previously effective Factor VIII product. ■ Plasma-derived products may contain infectious agents that can cause disease (e.g., viruses and, theoretically, the Creutzfeldt-Jakob disease agent). The risk that these products will transmit an infectious agent has been reduced by screening plasma donors, testing for the presence of viruses, and inactivating and/or removing certain viruses during manufacturing. Hepatitis A and parvovirus 19 have been reported infrequently with plasma-based products, usually in immunocompromised patients or pregnant women. ■ Intravascular hemolysis can occur when large volumes of plasma-derived products are given to individuals with blood groups A, B, or AB. Monitor for progressive anemia. ■ Components of some products may contain latex; use caution to avoid a hypersensitivity reaction. ■ Hemophilic patients with cardiovascular risk factors or diseases may be at the same risk as nonhemophilic patients for developing cardiovascular events when clotting has been normalized by treatment with factor VIII. ■ Treatment of choice when volume or RBC replacement is not needed; avoids hypervolemia and hyperproteinemia. ■ Not useful to treat other coagulation factor deficiencies. ■ Catheter-related infections may occur if antihemophilic factor is administered via central venous access devices (CVADs). These infections have not been associated with the actual AHF product. ■ Desmopressin may be the preferred treatment for mild to moderate hemophilia A (AHF levels that are at least 5%).

Monitor:

All products:

Identification of factor VIII deficiency with determination of circulating AHF levels should be obtained before administration. Monitor plasma factor VIII activity by the one-stage clotting assay (except **Afstyla** and **Jivi** [see below]) to confirm that adequate factor VIII levels have been achieved and maintained. Adjust dose as indicated. ■ Monitor heart rate and blood pressure before and during treatment. ■ Monitor for the development of factor VIII inhibitors. Should be suspected if factor VIII plasma levels are not obtained or if bleeding is not controlled with an appropriate dose. The Bethesda inhibitor assay determines if factor VIII inhibitors are present. Bethesda Units (BU) are used to report inhibitor levels. ■ Monitor patients with a known or suspected inhibitor to factor VIII more frequently. ■ Monitor for S/S of a hypersensitivity reaction (e.g., anaphylaxis, angioedema, chest or throat tightness, dizziness, dyspnea, face swelling, fever, flushing, hypotension, laryngeal edema, nausea, paresthesia, pruritus, rash, tachycardia, urticaria, vomiting, wheezing). ■ Monitor for signs of bleeding. ■ Monitor hemoglobin and hematocrit. ■ Monitor patients with CVADs for S/S of infection. ■ See Precautions.

Afstyla:

Monitoring of plasma factor VIII levels by a chromogenic assay is preferred over the one-stage clotting assay routinely used in U.S. clinical laboratories (most accurately reflects the clinical hemostatic potential of Afstyla). The one-stage clotting assay result underestimates the factor VIII activity level compared with the chromogenic assay result by approximately one-half. ***If the one-stage clotting assay is used, multiply the result by a conversion factor of 2 to determine the patient's factor VIII activity level.***

Jivi:

Monitor the Factor VIII activity of Jivi in plasma using either a validated chromogenic substrate assay or a validated one-stage clotting assay. Validation required to prevent underestimation or overestimation of Factor VIII activity; see manufacturer's prescribing information.

Obizur:

Monitor factor VIII activity 30 minutes and 3 hours after initial dose and 30 minutes after subsequent doses. Use of the Nijmegen-Bethesda inhibitor assay is recommended.

Patient Education:

All products:

Read manufacturer-supplied patient product information. ■ Instruction for self-administration and proper storage and preparation may be appropriate. ■ Discontinue antihemophilic factor and immediately report S/S of a hypersensitivity reaction (e.g., hives, hypotension, itching, rash, tightness of the chest, wheezing). ■ Review prescription and nonprescription medications with a health care provider. ■ Contact provider for lack of clinical response. May indicate development of inhibitors. ■ Consult with health care provider before travel. Bring an adequate supply of AHF based on current treatment regimen.

Plasma-derived products:

Report S/S of hepatitis A (e.g., persistent poor appetite and tiredness, fever, dark urine, yellowing of the skin, nausea, vomiting, and abdominal pain). ■ Report S/S of parvovirus B19 (e.g., chills, drowsiness, fever, and runny nose followed 2 weeks later by a rash and joint pain).

Maternal/Child:

Use during pregnancy only if clearly needed. ■ Use caution during breast-feeding. ■ Advate, Afstyla, Helixate FS, Kogenate FS, Kovaltry, Kovaltry Bio-Set, and Recombinate have been used in pediatric patients of all ages, including infants. Other formulations are indicated for use in pediatric patients but did not include newborns in clinical trials. ■ ***All products:*** Clearance (based on kg body weight) is higher in the pediatric population. Half-life is shorter; see Dose Adjustments. ■ ***Jivi:*** Safety and effectiveness in pediatric patients under 12 years of age has not been established. Jivi is not indicated in this age-group. Adverse reactions due to immune response to PEG, including hypersensitivity reactions and/or loss of drug effect, have been observed; see Precautions. ■ ***Obizur:*** Safety and efficacy for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently from younger subjects.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

May respond to reduced rate of administration. Serious adverse reactions include hypersensitivity reactions and factor VIII inhibitors.

Plasma-based AHF:

Abdominal pain, blurred vision, bradycardia, chills, clouding or loss of consciousness, diarrhea, dizziness, dysgeusia, factor VIII inhibition, fever, flushing, headache, hemolytic anemia, hyperfibrinogenemia, hypersensitivity reactions (anaphylaxis, backache, chills, erythema, fever, hives, hypotension, nausea, pruritus, rash, tightness of chest, urticaria, wheezing), lethargy, paresthesias, somnolence, stinging at infusion site, tachycardia, tingling, or vomiting may occur.

Recombinant products:

The most commonly reported side effects included arthralgia, back pain, central venous access device–associated infections, chills, cough, dizziness, dry mouth, epistaxis, fever, flushing, headache, increased hepatic enzymes, infusion site reactions (e.g., inflammation, pain), inhibitor formation in previously untreated or minimally treated patients, limb injury, malaise, nasopharyngitis, nausea, nonneutralizing anti–factor VIII antibody formation, paresthesia, skin-associated hypersensitivity reactions (e.g., erythema, pruritus, rash, urticaria), and generalized hypersensitivity reactions, including anaphylaxis.

Obizur:

In clinical trials, development of inhibitors to porcine factor VIII occurred in more than 5% of patients.

Jivi:

Anti-PEG antibodies.

ANTIDOTE

Most side effects usually subside spontaneously in 15 to 20 minutes and are generally related to the rate of infusion. Keep the physician informed. Slow or discontinue infusion temporarily if heart rate increases or beginning S/S of a hypersensitivity reaction occur. Discontinue immediately and treat hypersensitivity reactions (antihistamines, epinephrine, corticosteroids). Premedication with antihistamines (e.g., diphenhydramine) may be considered for patients with previous hypersensitivity reactions. Resuscitate as necessary.

ANTIHEMOPHILIC FACTOR ■ VON WILLEBRAND FACTOR COMPLEX (HUMAN)

(an-tie-hee-moe-**FIL**-ik **FAK**-tor)
Alphanate, Humate-P
Antihemorrhagic

USUAL DOSE (International units [IU])

Pretreatment:

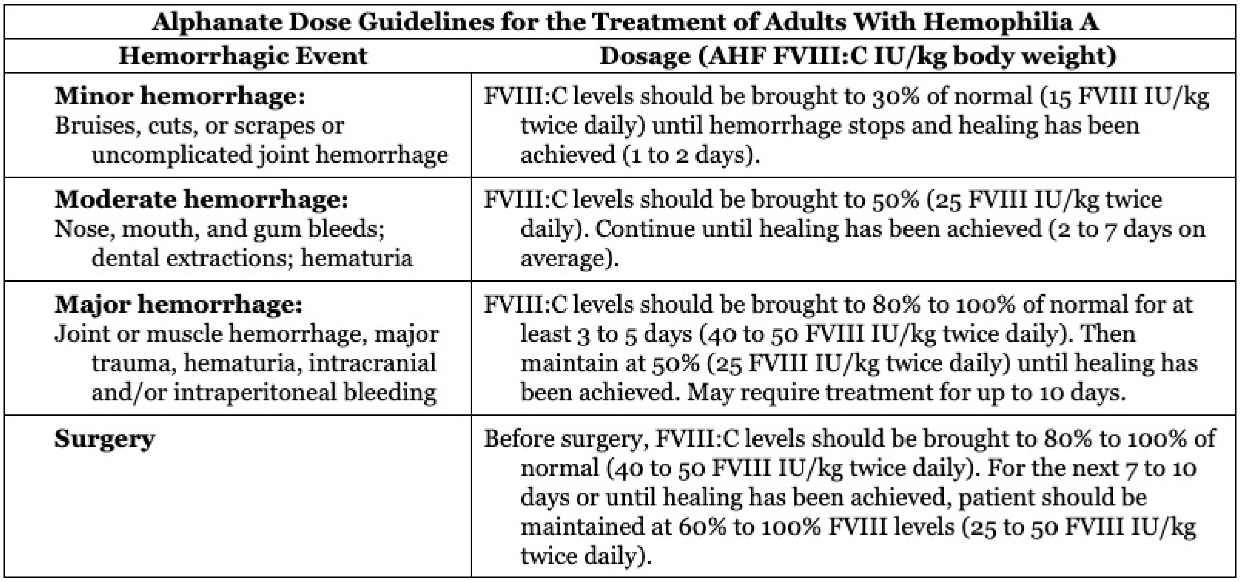
See Precautions.

Completely individualized. Based on degree of deficiency, desired antihemophilic factor level, body weight, severity of bleeding, and presence of factor VIII inhibitors. One international unit (IU) of factor VIII or 1 IU of von Willebrand factor:Ristocetin Cofactor (vWF:RCof) is approximately equal to the level of factor VIII activity or vWF:RCof found in 1 mL of fresh pooled human plasma.

Alphanate

Treatment of hemophilia A (adults):

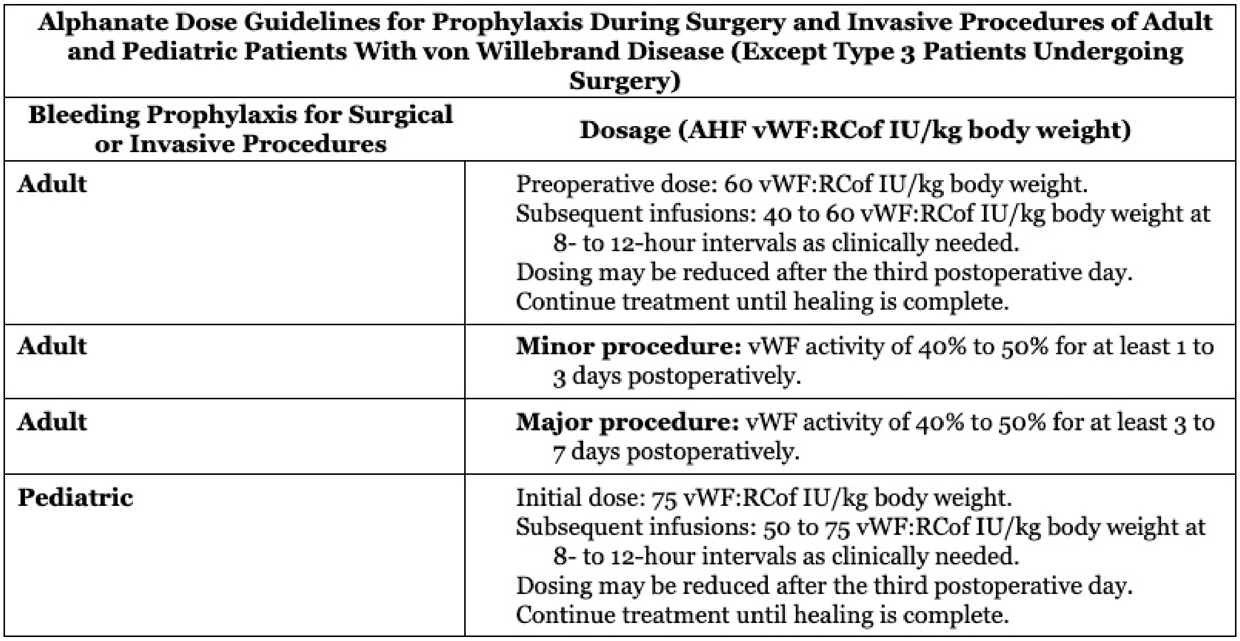
Dose requirements and frequency are calculated on the basis of an expected initial response of 2% of normal FVIII:C IU/kg of body weight administered. Assess adequacy of treatment by clinical effects and monitoring of factor VIII activity. See Precautions. The following general dosages are recommended for adult patients:



Alphanate Dose Guidelines for the Treatment of Adults With Hemophilia A

Hemorrhagic Event	Dosage (AHF FVIII:C IU/kg body weight)
Minor hemorrhage: Bruises, cuts, or scrapes or uncomplicated joint hemorrhage	FVIII:C levels should be brought to 30% of normal (15 FVIII IU/kg twice daily) until hemorrhage stops and healing has been achieved (1 to 2 days).
Moderate hemorrhage: Nose, mouth, and gum bleeds; dental extractions; hematuria	FVIII:C levels should be brought to 50% (25 FVIII IU/kg twice daily). Continue until healing has been achieved (2 to 7 days on average).
Major hemorrhage: Joint or muscle hemorrhage, major trauma, hematuria, intracranial and/or intraperitoneal bleeding	FVIII:C levels should be brought to 80% to 100% of normal for at least 3 to 5 days (40 to 50 FVIII IU/kg twice daily). Then maintain at 50% (25 FVIII IU/kg twice daily) until healing has been achieved. May require treatment for up to 10 days.
Surgery	Before surgery, FVIII:C levels should be brought to 80% to 100% of normal (40 to 50 FVIII IU/kg twice daily). For the next 7 to 10 days or until healing has been achieved, patient should be maintained at 60% to 100% FVIII levels (25 to 50 FVIII IU/kg twice daily).

IU, International unit.



Alphanate Dose Guidelines for Prophylaxis During Surgery and Invasive Procedures of Adult and Pediatric Patients With von Willebrand Disease (Except Type 3 Patients Undergoing Surgery)

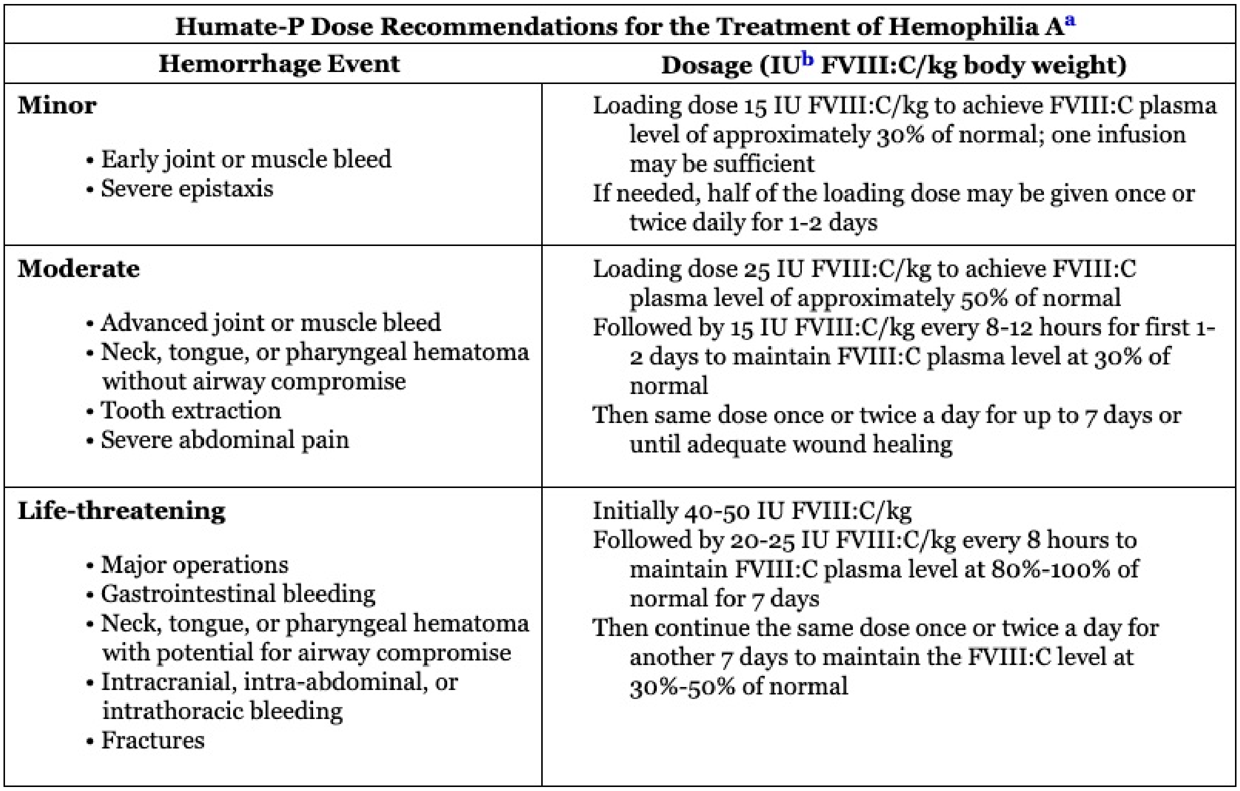
Bleeding Prophylaxis for Surgical or Invasive Procedures	Dosage (AHF vWF:RCof IU/kg body weight)
Adult	Preoperative dose: 60 vWF:RCof IU/kg body weight. Subsequent infusions: 40 to 60 vWF:RCof IU/kg body weight at 8- to 12-hour intervals as clinically needed. Dosing may be reduced after the third postoperative day. Continue treatment until healing is complete.
Adult	**Minor procedure:** vWF activity of 40% to 50% for at least 1 to 3 days postoperatively.
Adult	**Major procedure:** vWF activity of 40% to 50% for at least 3 to 7 days postoperatively.
Pediatric	Initial dose: 75 vWF:RCof IU/kg body weight. Subsequent infusions: 50 to 75 vWF:RCof IU/kg body weight at 8- to 12-hour intervals as clinically needed. Dosing may be reduced after the third postoperative day. Continue treatment until healing is complete.

IU, International unit.

Humate-P

Treatment of hemophilia A (adults):

As a general rule, 1 IU of factor VIII activity per kg body weight will increase the circulating factor VIII level by approximately 2 IU/dL. Assess adequacy of treatment by clinical effects and monitoring of factor VIII activity. See Precautions. The following general dosages are recommended for adult patients:



Humate-P Dose Recommendations for the Treatment of Hemophilia A[a]

Hemorrhage Event	Dosage (IU[b] FVIII:C/kg body weight)
Minor • Early joint or muscle bleed • Severe epistaxis	Loading dose 15 IU FVIII:C/kg to achieve FVIII:C plasma level of approximately 30% of normal; one infusion may be sufficient If needed, half of the loading dose may be given once or twice daily for 1-2 days
Moderate • Advanced joint or muscle bleed • Neck, tongue, or pharyngeal hematoma without airway compromise • Tooth extraction • Severe abdominal pain	Loading dose 25 IU FVIII:C/kg to achieve FVIII:C plasma level of approximately 50% of normal Followed by 15 IU FVIII:C/kg every 8-12 hours for first 1-2 days to maintain FVIII:C plasma level at 30% of normal Then same dose once or twice a day for up to 7 days or until adequate wound healing
Life-threatening • Major operations • Gastrointestinal bleeding • Neck, tongue, or pharyngeal hematoma with potential for airway compromise • Intracranial, intra-abdominal, or intrathoracic bleeding • Fractures	Initially 40-50 IU FVIII:C/kg Followed by 20-25 IU FVIII:C/kg every 8 hours to maintain FVIII:C plasma level at 80%-100% of normal for 7 days Then continue the same dose once or twice a day for another 7 days to maintain the FVIII:C level at 30%-50% of normal

[a] In all cases, the dose should be adjusted individually by clinical judgment of the potential for compromise of a vital structure and by frequent monitoring of factor VIII activity in the patient's plasma.

[b] *IU,* International unit.

Treatment of von Willebrand Disease (vWD) (adults and pediatric patients):

As a rule, 40 to 80 IU vWF:RCof (corresponding to 16 to 32 IU factor VIII in Humate-P) per kg body weight given every 8 to 12 hours. Repeat doses are administered as needed based on monitoring of appropriate clinical and laboratory measures. Expected levels of vWF:RCof are based on an expected in vivo recovery of 1.5 IU/dL rise per IU/kg vWF:RCof administered. The administration of 1 IU of factor VIII per kg body weight can be expected to lead to a rise in circulating vWF:RCof of approximately 3.5 to 4 IU/dL. The following general dosages are recommended for adult and pediatric patients:

Humate-P Dose Recommendations for Treatment of von Willebrand Disease in Adult and Pediatric Patients

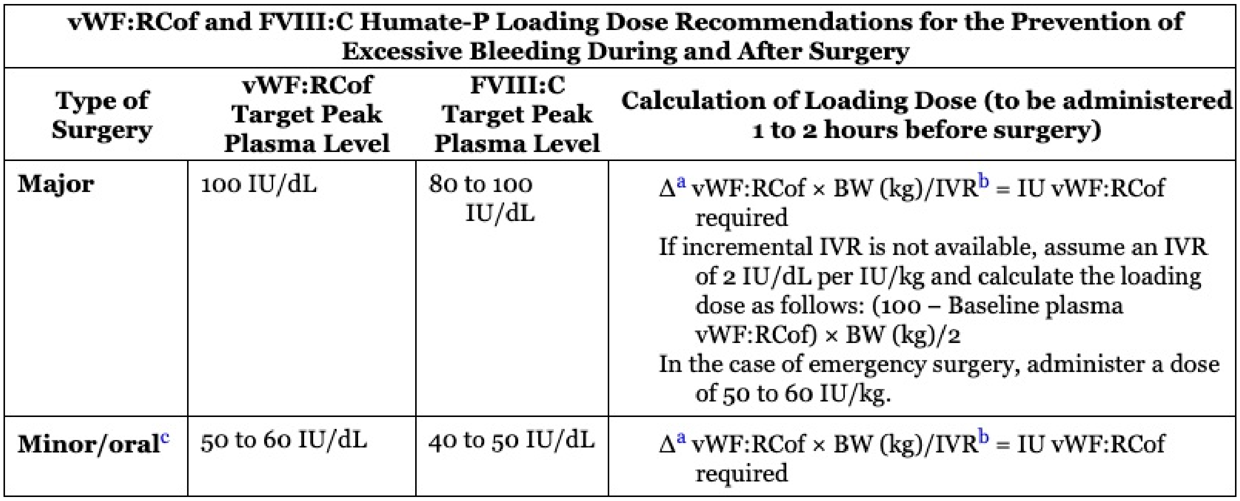
Classification	Hemorrhage	Dosage (IU[a] vWF:RCof/kg body weight)
TYPE 1		
Mild *(Where use of desmopressin is known or suspected to be inadequate)* Baseline vWF:RCof activity typically >30% of normal (i.e., >30 IU/dL)	**Major (examples)** • Severe or refractory epistaxis • GI bleeding • CNS trauma • Traumatic hemorrhage	Loading dose 40 to 60 IU/kg Then 40 to 50 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 50 IU/kg daily for a total of up to 7 days of treatment
Moderate or Severe Baseline vWF:RCof activity typically <30% of normal (i.e., <30 IU/dL)	**Minor (examples)** • Epistaxis • Oral bleeding • Menorrhagia	40 to 50 IU/kg (1 or 2 doses)
	Major (examples) • Severe or refractory epistaxis • GI bleeding • CNS trauma • Hemarthrosis • Traumatic hemorrhage	Loading dose of 50 to 75 IU/kg Then 40 to 60 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 60 IU/kg daily for a total of up to 7 days of treatment *Factor VIII:C levels should be monitored and maintained according to the guidelines for hemophilia A therapy*[b]
TYPE 2 (ALL VARIANTS) AND TYPE 3		
	Minor (clinical indications above)	40 to 50 IU/kg (1 or 2 doses)
	Major (clinical indications above)	Loading dose of 60 to 80 IU/kg Then 40 to 60 IU/kg every 8 to 12 hours for 3 days to keep the nadir level of vWF:RCof >50% of normal (i.e., >50 IU/dL) Then 40 to 60 IU/kg daily for a total of up to 7 days of treatment *Factor VIII:C levels should be monitored and maintained according to the guidelines for hemophilia A therapy*[b]

[a] IU, International unit.

[b] In instances where both FVIII and vWF levels must be monitored.

Prevention of excessive bleeding during and after surgery in vWD:

In the case of emergency surgery, administer a loading dose of 50 to 60 IU/kg Humate-P and closely monitor the patient's trough coagulation factor levels. Measurement of incremental in vivo recovery (IVR) and assessment of baseline plasma vWF:RCof and FVIII:C levels are recommended in all patients before surgery. As shown in the following charts, calculation of the loading dose requires four values: the target peak plasma vWF:RCof level, the baseline vWF:RCof level, body weight (BW) in kilograms, and IVR. If individual recovery values are not available, a standardized loading dose can be used based on an assumed vWF:RCof IVR of 2 IU/dL per IU/kg of vWF:RCof product administered.



vWF:RCof and FVIII:C Humate-P Loading Dose Recommendations for the Prevention of Excessive Bleeding During and After Surgery

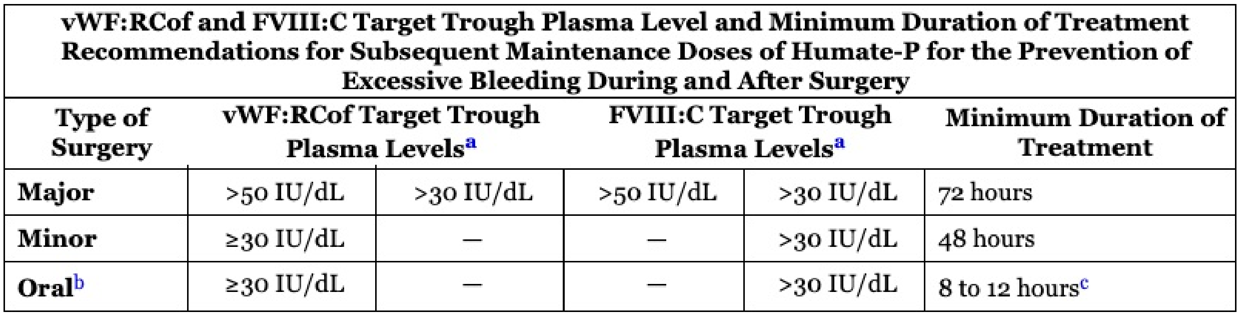
Type of Surgery	vWF:RCof Target Peak Plasma Level	FVIII:C Target Peak Plasma Level	Calculation of Loading Dose (to be administered 1 to 2 hours before surgery)
Major	100 IU/dL	80 to 100 IU/dL	Δ[a] vWF:RCof × BW (kg)/IVR[b] = IU vWF:RCof required If incremental IVR is not available, assume an IVR of 2 IU/dL per IU/kg and calculate the loading dose as follows: (100 − Baseline plasma vWF:RCof) × BW (kg)/2 In the case of emergency surgery, administer a dose of 50 to 60 IU/kg.
Minor/oral[c]	50 to 60 IU/dL	40 to 50 IU/dL	Δ[a] vWF:RCof × BW (kg)/IVR[b] = IU vWF:RCof required

IU, International unit.

[a] Δ = Target peak plasma vWF:RCof − Baseline plasma vWF:RCof.

[b] IVR = Incremental recovery as measured in the patient.

[c] Oral surgery is defined as removal of fewer than three teeth, if the teeth are nonmolars and have no bony involvement. Removal of more than one impacted wisdom tooth is considered major surgery due to the expected difficulty of the surgery and the expected blood loss, particularly in subjects with type 2A or type 3 vWD. Removal of more than two teeth is considered major surgery in all patients.



vWF:RCof and FVIII:C Target Trough Plasma Level and Minimum Duration of Treatment Recommendations for Subsequent Maintenance Doses of Humate-P for the Prevention of Excessive Bleeding During and After Surgery

Type of Surgery	vWF:RCof Target Trough Plasma Levels[a]		FVIII:C Target Trough Plasma Levels[a]		Minimum Duration of Treatment
Major	>50 IU/dL	>30 IU/dL	>50 IU/dL	>30 IU/dL	72 hours
Minor	≥30 IU/dL	—	—	>30 IU/dL	48 hours
Oral[b]	≥30 IU/dL	—	—	>30 IU/dL	8 to 12 hours[c]

IU, International unit.

[a] Trough levels for either coagulation factor should not exceed 100 IU/dL.

[b] See note on oral surgery in previous chart.

[c] At least one maintenance dose following surgery based on individual pharmacokinetic values.

PEDIATRIC DOSE

Treatment of hemophilia A (unlabeled):

For immediate control of bleeding, follow the general recommendations for dosing and administration for adults. See Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

Adjust subsequent doses based on FVIII:C plasma level achieved or as outlined in specific charts.

DILUTION

Consult individual product instructions in the package insert; each product has a specific process for dilution. Information may be updated frequently. **Alphanate** provides diluent, a double-ended transfer needle, and a microaggregate filter for use in administration. **Humate-P** provides diluent and a filter transfer set.

Alphanate and Humate-P:

Actual number of AHF units is shown on each vial. Use only the diluent provided and maintain strict aseptic technique. Use a plastic syringe to prevent binding to glass surfaces. Warm to room temperature (25° C [77° F]) before dilution and maintain throughout administration to avoid precipitation of active ingredients.

Filters:

Filters supplied by manufacturer; see Dilution.

Storage:

Alphanate: Refrigerate before use. Avoid freezing. May be stored at CRT for up to 2 months. Label vial with date removed from refrigeration. ***Humate-P:*** Store up to 25° C (up to 77° F). Avoid freezing. ***Alphanate and Humate-P:*** Do not refrigerate after reconstitution. Confirm expiration date on vial. Administer within 3 hours of reconstitution to ensure sterility. Discard any unused solution.

COMPATIBILITY

Compatibility information not available from manufacturer. Administration through a separate line without mixing with other IV fluids or medications is generally recommended for these products; consult a pharmacist.

RATE OF ADMINISTRATION

Inject solution slowly. Rapid administration may result in vasomotor reactions.
Humate-P recommends a maximum rate of 4 mL/min.
Alphanate recommends a maximum rate not to exceed 10 mL/min.

ACTIONS

A purified, sterile, lyophilized concentrate of antihemophilic factor (factor VIII) and von

Willebrand Factor (vWF). Factor VIII is an essential cofactor in the activation of factor X, leading ultimately to the formation of thrombin and fibrin. It is the specific clotting factor deficient in patients with hemophilia A (classic hemophilia). vWF is important for correcting the coagulation defect in patients with von Willebrand disease (vWD). It promotes platelet aggregation and platelet adhesion on damaged vascular endothelium and acts as a stabilizing carrier protein for the procoagulant protein factor VIII. vWF activity is measured with an assay that uses an agglutinating cofactor called Ristocetin (RCof). The vWF:RCof assay provides a quantitative measurement of vWF function by determining how well vWF helps platelets adhere to one another. Reduced vWF:RCof activity indicates a deficiency of vWF. Following administration of FVIII/vWF, there is a rapid increase of plasma factor VIII activity, followed by a rapid decrease in activity and then a slower rate of decrease in activity. The mean initial half-life in hemophilic patients is 8.3 to 27.5 hours with Alphanate and 12.2 hours (range: 8.4 to 17.4 hours) with Humate-P. In patients with vWD, bleeding time decreases. Antihemophilic factor/von Willebrand Factor Complex is obtained from pooled human fresh frozen plasma. Multiple methods of purification are used to inactivate infectious agents, including viruses.

INDICATIONS AND USES

Alphanate

Prevention and control of bleeding in patients with factor VIII deficiency due to hemophilia A or acquired factor VIII deficiency. ■ Prophylaxis for surgical and/or invasive procedures in adult and pediatric patients with von Willebrand disease (vWD) (type 1 or 2) in which the use of desmopressin is either ineffective or contraindicated. ■ Not indicated for patients with severe vWD (type 3).

Humate-P

Treatment and prevention of bleeding in adult patients with hemophilia A. ■ Treatment of spontaneous and trauma-induced bleeding episodes and prevention of excessive bleeding during and after surgery in adult and pediatric patients with severe vWD or with mild or moderate vWD in which the use of desmopressin is known or suspected to be inadequate. ■ Safety and efficacy of prophylactic dosing to prevent spontaneous bleeding and to prevent excessive bleeding related to surgery have not been established in patients with vWD.

CONTRAINDICATIONS

Alphanate:

None known when used as indicated.

Humate-P:

History of anaphylactic or severe systemic response to AHF-vWF preparations or known hypersensitivity to any of its components.

PRECAUTIONS

Alphanate and Humate-P:

For IV use only. ■ Important to establish that coagulation disorder is caused by factor VIII or vWF deficiency. Not useful in treatment of other deficiencies. ■ Health care professionals should use caution during administration; may have risk of exposure to viral infection. ■ Manufactured from human plasma. Risk of transmitting infectious agents (e.g., HIV, hepatitis and, theoretically, Creutzfeldt-Jakob disease) has been greatly reduced by screening, testing, and manufacturing techniques. However, risk of transmission cannot be totally eliminated. ■ Hepatitis A and B vaccines are recommended for patients receiving plasma derivatives. ■ Thrombotic events have been reported. Use caution in patients with known risk factors for thrombosis. Incidence may be higher in females. ■ Inhibitors may develop with large or frequent doses; see Monitor.

Monitor:

Complex contains blood group isoagglutinins (anti-A and anti-B). When very large or frequently repeated doses are needed, as when inhibitors are present or when presurgical and postsurgical care is involved, patients of blood groups A, B, and AB should be monitored for signs of intravascular hemolysis and decreasing hematocrit values; see Antidote. ■ Replacement therapy should be monitored by appropriate coagulation tests, especially in cases involving major surgery. Monitor factor VIII and vWF:RCof as indicated in dosing guidelines.

Patient Education:

Prophylactic hepatitis A and hepatitis B vaccines recommended. ■ Report symptoms of possibly transmitted viral infections immediately. Symptoms may include anorexia, arthralgias, fatigue, jaundice, low-grade fever, nausea, or vomiting. ■ Report rash or any other sign of hypersensitivity reaction promptly.

Maternal/Child:

Category C: use only if clearly needed. ■ Adequate and well-controlled studies with long-term evaluation of joint damage have not been done in pediatric patients. Joint damage may result from suboptimal treatment of hemarthroses. ■ Safety and effectiveness for use in neonates with vWD have not been established. Has been used safely in infants, children, and adolescents with vWD.

Elderly:

Numbers insufficient to determine differences in response compared with younger adults. Consider overall status in dosing.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Alphanate and Humate-P:

Usually well tolerated. Rare cases of hypersensitivity reactions, including anaphylaxis, have been reported (symptoms may include chest tightness, edema, fever, pruritus, rash, throat tightness). Other reported side effects include chills, headache, lethargy, nausea and vomiting, paresthesia, phlebitis, somnolence, and vasodilation. Inhibitors of factor VIII may occur.

Post-Marketing:

Alphanate: In addition to the above, cardiac arrest, femoral venous thrombosis, flushing, itching, joint pain, pulmonary embolus, seizure, shortness of breath, swelling of the parotid gland, urticaria. ***Humate-P:*** Hypersensitivity reactions (including anaphylaxis), development of inhibitors to factor VIII, hemolysis, hypervolemia, thromboembolic complications.

ANTIDOTE

Keep physician informed of all side effects. If mild reactions occur (mild allergic reaction, chills, nausea, or stinging at the infusion site) and additional treatment is indicated, a product from a different lot should be considered. Discontinue immediately at first sign of a moderate to severe hypersensitivity reaction. Treat as necessary (antihistamines, epinephrine, corticosteroids). Development of acute hemolytic anemia, increased bleeding tendency, or hyperfibrinogenemia may require transfusion with Type O red blood cells. Discontinue administration of Alphanate/Humate-P and consider alternative therapy. Resuscitate as necessary.

ANTI-INHIBITOR COAGULANT COMPLEX BBW

(an-**TIE**-in-**HIH**-bih-tor coe-**AG**-you-lant **COM**-plex)
Feiba
Antihemorrhagic

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

A unit of **Feiba (nanofiltered and vapor heated)** is expressed as factor VIII inhibitor bypassing activity. Identification of factor VIII inhibitor levels and PT mandatory before administration.

Feiba

Range is 50 to 100 units/kg.
Specific suggested dosing regimens include:

Joint hemorrhage:

50 units/kg; repeat at 12-hour intervals if indicated. May be increased to 100 units/kg if indicated. Continue treatment until clinical improvement (e.g., mobilization of the joint, reduction of swelling, relief of pain). ***Do not exceed 200 units/kg/24 hr.***

Mucous membrane bleeding:

50 units/kg; repeat at 6-hour intervals if indicated. Monitor visible bleeding sites and hematocrit closely. May be increased to 100 units/kg every 6 hours for up to 2 doses if bleeding does not stop. ***Do not exceed 200 units/kg/24 hr.***

Serious soft tissue hemorrhage:

100 units/kg; repeat at 12-hour intervals if indicated.

Other severe hemorrhage (e.g., CNS bleeding):

100 units/kg; repeat at 12-hour intervals if indicated. Feiba may be indicated at 6-hour intervals until clear clinical improvement occurs.

DILUTION

Actual number of units shown on each vial. Use only the diluent provided and maintain strict aseptic technique. Bring to room temperature before reconstitution. Follow manufacturer's guidelines for reconstitution using the BAXJECT device. May stick to sides of glass syringes; use of plastic syringes recommended. Gently swirl. Do not shake. May be given through Y-tube or three-way stopcock of infusion set. To avoid hypotension from prekallikrein activator (PKA), give **Feiba** within 3 hours of reconstitution.

Filters:

The manufacturer of ***Feiba*** uses a needleless transfer device and has no recommendation for use of an in-line filter.

Storage:

Within the indicated shelf life, may be stored in original packaging to protect from light at RT (not to exceed 25° C [77° F]). Do not freeze.

COMPATIBILITY

Compatibility information not available from manufacturer. Administration through a separate line without mixing with other IV fluids or medications is generally recommended. If anti-inhibitor coagulant is given as a continuous IV, one source says heparin 5 to 10 units/mL of concentrate may be added to avoid thrombophlebitis; consult a pharmacist.

RATE OF ADMINISTRATION

If symptoms of too-rapid infusion (headache, flushing, changes in BP or pulse rate) occur, discontinue until symptoms subside. Restart at a lower rate.

Feiba:

Do not exceed 2 units/kg/min.

ACTIONS

An activated prothrombin complex prepared from pooled human plasma. Controls bleeding in patients with factor VIII inhibitors. Mechanism of action is not well understood. Onset of response is usually within 12 hours. Peak response is usually seen within 36 to 72 hours.

Feiba:

1 unit of activity is the amount of anti-inhibitor coagulant complex (AICC) that will shorten the aPTT of a high-titer factor VIII inhibitor reference plasma to 50% of the blank value.

INDICATIONS AND USES

Prophylaxis and treatment of hemorrhagic complications in hemophiliacs (hemophilia A or B) with factor VIII inhibitors who are bleeding or will undergo elective or emergency surgery. Anti-inhibitor coagulant complex (AICC) is most frequently indicated if presenting factor VIII inhibitor levels are above 5 to 10 Bethesda units (BU) or rise to that level following treatment with antihemophilic factor (AHF). Patients whose factor VIII inhibitor levels are between 5 and 10 BU and whose inhibitor levels remain at those levels may be treated with either AHF or AICC. Patients whose inhibitor levels are less than or equal to 5 BU and whose inhibitor levels remain at those levels may be treated with AHF.

Unlabeled uses:

Feiba has been used in the prophylaxis and treatment of hemorrhagic complications in nonhemophiliacs with acquired inhibitors to factors VIII, XI, and XII.

CONTRAINDICATIONS

Patients with a normal coagulation mechanism; patients with significant signs of DIC; treatment of bleeding due to coagulation factor deficiencies in the absence of inhibitors to coagulation factors VIII or IX.

PRECAUTIONS

Anamnestic responses (development of antibodies, reducing effectiveness of the drug) with a rise in factor VIII inhibitor titers have been seen in up to 20% of cases. ■ Thrombotic and thromboembolic events have been reported (e.g., DIC, venous thrombosis, pulmonary embolism, MI, and stroke). Risk of complications may be increased in surgical patients, in patients with thrombotic risk factors, and in patients receiving higher doses. Patients receiving more than 100 units/kg/dose or 200 mg/kg/day are at increased risk for DIC or acute coronary ischemia. Use high doses only as long as necessary to stop bleeding. ■ Patients with DIC, advanced atherosclerotic disease, crush injury, septicemia, or concomitant treatment with recombinant factor VIIa (e.g., NovoSeven RT) have an increased risk of developing thrombotic events due to circulating tissue factor (TF) or predisposing coagulopathy. ■ Use with caution and only if there are no therapeutic alternatives in patients at risk for DIC or arterial or venous thrombosis or in patients with existing thrombotic conditions (e.g., MI or venous thrombosis). ■ Use with caution in patients with a history of coronary heart disease, liver disease, or postoperative immobilization, in the elderly, and in neonates; weigh benefits versus risk. ■ Do not use Feiba for the treatment of bleeding episodes resulting from coagulation factor deficiencies. ■ Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection. ■ See Drug/Lab Interactions.

Monitor:

Monitor PT before and after treatment. Use only accurate means of treatment evaluation; see Drug/Lab Interactions. ■ Monitor vital signs before, during, and after the infusion. ■ Monitor for S/S of acute coronary ischemia, DIC, and other thrombotic or thromboembolic events (e.g., changes in BP and HR, chest pain, cough, respiratory distress); see Antidote. ■ Laboratory indications of DIC may include decreased fibrinogen, decreased platelet count, and/or the presence of fibrin-fibrinogen degradation products (FDP) or significantly prolonged TT, PT, or PTT. ■ Monitor for S/S of a hypersensitivity reaction (e.g., rash, shortness of breath).

Patient Education:

Manufactured from pooled human plasma. Possibility of viral transmission exists. Promptly report S/S of viral infections (e.g., chills, drowsiness, fever, runny nose followed by joint pain, rash, and/or S/S of hepatitis A [e.g., days to weeks of poor appetite, low-grade fever, and tiredness followed by abdominal pain, dark urine, jaundice, nausea, vomiting]).

Maternal/Child:

Category C: use only if clearly needed. ■ Data not available for use in newborns. ■ Safety for use in breast-feeding not established.

Elderly:

May have increased risk for thromboembolic complications.

DRUG/LAB INTERACTIONS

Not recommended for use with **antifibrinolytic products** (aminocaproic acid, tranexamic acid). Feiba has been used with **antifibrinolytics;** however, they should be used with caution and not administered until at least 12 hours after Feiba. ■ aPTT, WBCT, and other **clotting factor tests** do not correlate with clinical improvement. Attempts to normalize these values may lead to overdose and DIC.

SIDE EFFECTS

Anaphylaxis, bradycardia, chest pain, chills, cough, decreased fibrinogen concentration, decreased platelet count, DIC, fever, flushing, headache, hypertension, hypotension, myocardial infarction, prolonged PT, prolonged PTT, prolonged thrombin time, respiratory distress, tachycardia, thrombosis or thromboembolism, urticaria. Consider risk potential of contracting AIDS or hepatitis.

Overdose:

Increased risk for DIC, MI, or thromboembolism.

Post-Marketing:

Anaphylactic reaction, DIC, hypersensitivity, hypoaesthesia, facial hypoaesthesia, hypotension, injection site pain, thromboembolism, thrombosis.

ANTIDOTE

If side effects occur, discontinue the infusion and notify the physician. May be resumed at a slower rate or discontinued, or an alternate product may be used. Symptoms of DIC (BP and pulse rate changes, respiratory discomfort, chest pain, cough, prolonged clotting tests, cyanosis of hands and feet, persistent bleeding from puncture sites or mucous membranes) require discontinuation of the infusion and immediate treatment. Treat anaphylaxis or other hypersensitivity reactions (changes in BP or HR [may indicate prekallikrein activity]) with antihistamines, epinephrine, corticosteroids and resuscitate as necessary.

ANTITHROMBIN III (HUMAN)

(an-tie-**THROM**-bin)
AT-III, Thrombate III
Anticoagulant
Antithrombotic
pH 6.5 to 7.5

USUAL DOSE (International units [IU])

Pretreatment:

See Precautions.

Antithrombin III:

Loading dose, maintenance dose, and dosing intervals are completely individualized based on confirmed diagnosis (see Precautions), patient weight, clinical condition, degree of deficiency, type of surgery or procedure involved, physician judgment, desired level of antithrombin III (AT-III), and actual plasma levels achieved as verified by appropriate lab tests. One unit/kg should raise the level of AT-III by 1.4%. The desired AT-III level after the first dose should be about 120% of normal (normal is 0.1 to 0.2 Gm/L). AT-III levels must be maintained at normal or at least above 80% of normal for 2 to 8 days depending on individual patient factors. Usually achieved by administration of a maintenance dose once daily. Concomitant administration of heparin usually indicated; see Drug/Lab Interactions.

Calculate the initial loading dose using the following formula (assumes a plasma volume of 40 mL/kg):

$$\text{Dosage units} = \frac{(\text{Desired AT-III level } [\%] - \text{ Baseline AT-III } [\%]) \times \text{Body weight (kg)}}{\div 1.4\%}$$

For a 70-kg patient with a baseline AT-III level of 57% the initial dose of Thrombate III would be (120% − 57%) × 70 ÷ 1.4 = 3,150 International units (IU). Measurement of plasma levels is suggested pre-infusion, 20 minutes postinfusion (peak), 12 hours postinfusion, and preceding next infusion (trough). If recovery differs from the anticipated rise of 1.4% for each IU/kg, modify the formula accordingly. If the above patient has a 20-minute AT-III level of 147%, the increase in AT-III measured for each 1 IU/kg administered is (147% − 57%) × 70 kg ÷ 3,150 IU = 2% rise for each IU/kg administered. This in vivo recovery would be used to calculate future doses. A maintenance dose of approximately 60% of the loading dose every 24 hours is the average required to maintain plasma levels between 80% and 120%. Dose and interval based on plasma levels.

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

Diluent, double-ended needles for dilution, and filter needle for aspiration into a syringe are provided. Warm unopened diluent and concentrate to room temperature. Enter diluent bottle with double-ended transfer needle first. Enter vacuum concentrate bottle with double-ended transfer needle at a 45-degree angle. Direct diluent from above to sides of vial to gently moisten all contents. Remove diluent bottle and transfer needle; swirl continuously until completely dissolved. Draw into a syringe through the filter needle. Remove filter needle; replace with an administration set (not provided). For larger doses, several bottles may be drawn into one syringe. Use a separate filter needle for each bottle.

Filters:

Filter needle supplied by manufacturer; see Dilution. For larger doses, several bottles may be drawn into one syringe. Use a separate filter needle for each bottle.

Storage:

Store in refrigerator before dilution; avoid freezing. Do not refrigerate after reconstitution. Use within 3 hours of reconstitution.

COMPATIBILITY

Administration through a separate line without mixing with other IV fluids or medications is recommended.

RATE OF ADMINISTRATION

Too-rapid injection may cause dyspnea.
A single dose over 10 to 20 minutes.

ACTIONS

Manufactured from human plasma, purified and heat treated through specific processes, AT-III is a plasma-based protein produced by the body to inactivate specific clotting proteins and control clot formation. Identical to heparin cofactor I, a factor in plasma necessary for heparin to exert its anticoagulant effect. It inactivates thrombin and the activated forms of factors IX, X, XI, and XII (all coagulation enzymes except factors VIIa and XIIIa). Increases AT-III levels within 30 minutes and has a half-life of up to 3 days.

INDICATIONS AND USES

Treatment of patients with hereditary AT-III deficiency to prevent thrombosis during surgical or obstetric procedures (replacement therapy) or during acute thrombotic episodes.

CONTRAINDICATIONS

None when used as indicated.

PRECAUTIONS

For IV use only. ■ Confirm diagnosis of hereditary AT-III deficiency based on a clear family history of venous thrombosis as well as decreased plasma AT-III levels and the exclusion of acquired deficiency. Present laboratory tests may not be able to identify all cases of congenital AT-III deficiency. ■ Every unit of plasma used to manufacture AT-III is tested and found nonreactive for HBsAg and negative for antibody to HIV by FDA-approved tests, then heat-treated by a special process. Even with these precautions, individuals who receive multiple infusions may develop viral infection, particularly non-A, non-B hepatitis. HIV infection remains a remote possibility. ■ May reverse heparin resistance.

Monitor:

See varying methods for measuring AT-III levels under Usual Dose. Should be measured at least twice daily until the patient is stabilized and peak and trough levels established, then measured daily. All blood work should be drawn immediately before the next infusion of AT-III.

Patient Education:

Inform of risks of thrombosis in connection with pregnancy and surgery and the fact that AT-III deficiency is hereditary.

Maternal/Child:

Neonatal AT-III levels should be measured immediately after birth if parents are known to have AT-III deficiency (fatal neonatal thromboembolism [e.g., aortic thrombi] has occurred). Treatment of the neonate should be under the direction of a physician knowledgeable about coagulation disorders. Normal full-term and premature infants have lower than adult averages of AT-III plasma levels. ■ Category B: use only if clearly indicated. Fetal abnormalities not noted when administered in the third trimester. ■ Safety for use in pediatric patients not established.

DRUG/LAB INTERACTIONS

Half-life of AT-III decreases with concurrent **heparin** treatment. The anticoagulant effect of heparin is enhanced, and a reduced dose of heparin and low-molecular-weight heparins (LMWHs) is indicated to avoid bleeding.

SIDE EFFECTS

Bowel fullness, chest pain, chest tightness, chills, cramps, dizziness, fever, film over eye, foul taste in mouth, hives, light-headedness, oozing and hematoma formation, and shortness of breath have occurred with Thrombate III. Some patients with acquired AT-III deficiency diagnosed with disseminated intravascular coagulation (DIC) have had diuretic and vasodilatory effects. Rapid infusion may cause dyspnea.

ANTIDOTE

Levels of 150% to 210% found in a few patients have not caused any apparent complications. Observe for bleeding. Reduce rate of infusion immediately for dyspnea. Decrease rate or interrupt infusion as indicated until side effects subside. Keep physician informed of patient’s lab values and condition.

ANTITHROMBIN RECOMBINANT

(an-tie-**THROM**-bin re-**KOM**-be-nant)
Atryn
Anticoagulant
Antithrombotic
pH 7

USUAL DOSE (International units [IU])

Pretreatment:

See Precautions. Baseline studies required; see Monitor.

Dose must be individualized for each patient and is based on the pretreatment level of functional antithrombin (AT) (expressed in percentage of normal) and on body weight in kilograms according to the following chart. Treatment goal is to restore and maintain functional AT activity levels between 80% and 120% (0.8 to 1.2 IU/mL) of normal. Treatment should be initiated before delivery or approximately 24 hours before surgery to ensure AT level is in the target range. Different dosing formulas are used for the treatment of surgical and pregnant patients. Pregnant women being treated with antithrombin recombinant for any peripartum or perioperative event, including a cesarean section, should be treated according to the dosing formula for pregnant women.

Antithrombin Recombinant Dosing Formula for Surgical Patients and Pregnant Women

Loading Dose (IU)	Maintenance Dose (IU/hr)
Surgical Patients	
$\frac{(100-\text{Baseline AT activity level})}{2.3} \times \text{Body weight (kg)}$	$\frac{(100-\text{Baseline AT activity level})}{10.2} \times \text{Body weight (kg)}$
Pregnant Women	
$\frac{(100-\text{Baseline AT activity level})}{1.3} \times \text{Body weight (kg)}$	$\frac{(100-\text{Baseline AT activity level})}{5.4} \times \text{Body weight (kg)}$

IU, International unit.

Check AT level just after surgery or delivery; AT activity may be rapidly decreased by surgery or delivery. If AT activity level is below 80%, administer an additional bolus dose to rapidly restore decreased AT activity level. Then restart the maintenance dose at the same rate of infusion as before the bolus. Monitor AT activity at least once or twice daily and adjust doses according to the chart in Dose Adjustments. Continue treatment until adequate follow-up anticoagulation is established.

DOSE ADJUSTMENTS

Antithrombin Recombinant AT Activity Monitoring and Dose Adjustment

Initial Monitor Time	AT Level	Dose Adjustment	Recheck AT Level
2 hr after initiation of treatment	<80%	Increase by 30%	2 hr after each dose adjustment
	80% to 100%	None	6 hr after initiation of treatment or dose adjustment
	>120%	Decrease by 30%	2 hr after each dose adjustment

DILUTION (International units [IU])

Bring vials to RT no more than 3 hours before reconstitution. Each vial contains approximately 1,750 IU; exact potency is stated on the carton and label. Immediately before use, each vial ***must*** be reconstituted with 10 mL SWFI. ***Do not shake.*** Draw the reconstituted solution from one or more vials into a sterile syringe. May administer reconstituted solution directly or may further dilute in an infusion bag containing NS (e.g., dilute to obtain a final concentration of 100 IU/mL). Administer using an infusion set with a 0.22-micron in-line filter.

Filters:

Use of a 0.22-micron in-line filter required during infusion.

Storage:

Before use, refrigerate vials between 2° and 8° C (36° and 46° F). Use reconstituted or diluted solution within 8 to 12 hours of preparation. Do not use beyond expiration date on vial. Discard unused product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. Because of specific use and unique formulation, consider administering through a separate line without mixing with other IV fluids or medications.

RATE OF ADMINISTRATION (International units [IU])

Loading dose:

Administer as an infusion over 15 minutes. Follow immediately with the **maintenance dose** as a continuous infusion at the calculated IU/hr rate.

ACTIONS (International units [IU])

A recombinant human antithrombin produced by DNA technology. A DNA coding sequence for human antithrombin and a mammary gland–specific DNA sequence are introduced into genetically engineered goats. The goats' milk contains the antithrombin. The amino acid sequence of antithrombin recombinant is identical to that of human plasma-derived antithrombin. Purified through numerous processes to eliminate potential viruses. AT is the principal inhibitor of thrombin and factor Xa. AT neutralizes the activity of thrombin and factor Xa by forming a complex that is rapidly removed from the circulation. When AT is bound to heparin, the ability of antithrombin to inhibit thrombin and factor Xa can be enhanced by greater than 300- to 1,000-fold. Half-life range based on IU/kg is 11.6 to 17.7 hours. This recombinant formulation has a shorter half-life and more rapid clearance compared with plasma-derived antithrombin (e.g., Thrombate III). Secreted in breast milk.

INDICATIONS AND USES

Prevention of perioperative and peripartum thromboembolic events in patients with hereditary antithrombin deficiency. ■ ***Not indicated for treatment*** of thromboembolic events in patients with hereditary antithrombin deficiency.

CONTRAINDICATIONS

Known hypersensitivity to goat and goat milk proteins.

PRECAUTIONS

For IV use only. ■ Confirm diagnosis of hereditary antithrombin deficiency. ■ Hypersensitivity reactions may occur at any time during the infusion, thus requiring discontinuation of the infusion. ■ The anticoagulant effect of drugs that use antithrombin to exert their anticoagulation (e.g., heparin, low-molecular-weight heparins such as enoxaparin [Lovenox]) may be altered when antithrombin recombinant is added or withdrawn. Avoid excessive or insufficient anticoagulation by monitoring coagulation tests suitable for the anticoagulant used (e.g., aPTT and anti-factor Xa activity). To avoid bleeding or thrombosis, perform these tests regularly and at close intervals, especially during the first hours after the start or withdrawal of antithrombin recombinant. ■ See Drug/Lab Interactions.

Monitor:

Specific coagulation tests are required before administration and throughout the infusion process; see Usual Dose and Precautions. ■ Monitor throughout the infusion for S/S of a hypersensitivity reaction (e.g., hives, hypotension, generalized urticaria, tightness of the chest, wheezing, and/or anaphylaxis). ■ Monitor for S/S of bleeding or thrombosis.

Patient Education:

Inform physician of a past or present allergy to goats or goat milk. ■ Promptly report S/S of a hypersensitivity reaction (e.g., rash, shortness of breath, wheezing). ■ Risk of bleeding increased when used with other anticoagulants. Report bleeding from any source.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. Studies have not shown that antithrombin recombinant increases the risk of fetal abnormalities if administered during the third trimester of pregnancy. Adverse reactions have not been reported in neonates born to women treated with antithrombin recombinant during clinical trials. ■ Indicated for prevention of thromboembolic events in women with hereditary antithrombin deficiency during labor and delivery. ■ Levels that appear in breast milk are estimated to be the same as in normal lactating women; however, use only if clearly needed and with caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether elderly patients respond differently than younger subjects. Dosing should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DRUG/LAB INTERACTIONS

The anticoagulant effect of **heparin and low-molecular-weight heparin** is enhanced by antithrombin. Concurrent use with these anticoagulants may alter the half-life of antithrombin. Concurrent use with **heparin, low-molecular-weight heparins** such as enoxaparin (Lovenox), **or other anticoagulants** that use antithrombin to exert their anticoagulant effect must be monitored clinically and biologically. To avoid excessive anticoagulation, perform regular coagulation tests (aPTT and, where appropriate, anti-factor Xa activity) at close intervals and adjust the dose of anticoagulant as indicated.

SIDE EFFECTS

Hemorrhage and infusion site reactions were most commonly reported. Hemorrhage may be serious (intra-abdominal, hemarthrosis, and postprocedural). Less common side effects include feeling hot, hematoma, hematuria, hepatic enzyme abnormalities, hypersensitivity reactions (including anaphylaxis), and noncardiac chest pain.

ANTIDOTE

Keep physician informed of patient’s lab values and condition. Discontinue the infusion if a hypersensitivity reaction occurs. ■ Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

ANTI-THYMOCYTE GLOBULIN (RABBIT) BBW

(an-tie-**THI**-mo-cite **GLOB**-you-lin)
Thymoglobulin, Atgam (equine)[a]
Immunosuppressant
pH 7 to 7.4

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

To reduce the incidence and intensity of side effects during the infusion of anti-thymocyte globulin; premedication 1 hour before the infusion with corticosteroids (e.g., dexamethasone), acetaminophen, and/or an antihistamine (e.g., diphenhydramine) is recommended.

Anti-thymocyte globulin:

1.5 mg/kg of body weight daily for 7 to 14 days. Given as an infusion into a high-flow vein. Used in conjunction with maintenance immunosuppression (e.g., tacrolimus [Prograf], mycophenolate [Cell-Cept]); see Drug/Lab Interactions.

DOSE ADJUSTMENTS

Reduce dose by one-half if WBC count is between 2,000 and 3,000 cells/mm^3 or if platelet count is between 50,000 and 75,000 cells/mm^3. ■ Consider withholding dose or stopping anti-thymocyte therapy if WBC count falls below 2,000 cells/mm^3 or platelets fall below 50,000 cells/mm^3.

DILUTION

Calculate the number of vials required (25 mg/vial); 5 mL of SWFI as diluent per vial is supplied. Drug and diluent must be warmed to room temperature before dilution. Absolute sterile technique required throughout dilution process. For each vial required use a new syringe and needle. Withdraw 5 mL of diluent and inject into lyophilized powder. Rotate vial gently until powder is completely dissolved. Do not shake. Each reconstituted vial contains 25 mg (5 mg/mL). Must be further diluted by transferring into 50 mL of infusion solution (saline or dextrose) for each 25 mg of anti-thymocyte globulin. Total volume is usually between 50 to 500 mL. Invert the infusion bag gently once or twice to mix the solution.

Filters:

Use of a 0.22-micron in-line filter recommended.

Storage:

Refrigerate and protect from light until removed to prepare for reconstitution. Do not freeze. Do not use after expiration date on vial. Use reconstituted vials within 4 hours. Use infusion solutions immediately. Discard unused drug.

COMPATIBILITY

Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of a high-flow vein and a 0.22-micron filter recommended. Well-tolerated and less likely to produce side effects (e.g., chills and fever) when administered at the recommended rate and the patient is premedicated.

Initial dose:

A total daily dose equally distributed over a minimum of 6 hours.

Subsequent doses:

A total daily dose equally distributed over a minimum of 4 hours.

ACTIONS

A purified, pasteurized, gamma immune globulin, obtained by immunization of rabbits with human thymocytes. Mechanism of action not fully understood. May induce immunosuppression by T-cell depletion and immune modulation. Made up of a variety of antibodies that recognize key receptors on T-cells (those cells responsible for attacking and rejecting a foreign substance within the body). Anti-thymocyte globulin antibodies can inactivate and kill these T-cells, thus reversing the rejection process. May prevent organ loss and reduce the need for retransplantation. T-cell depletion is usually observed within a day of initiating thymoglobulin therapy. Half-life averages 2 to 3 days but the drug remains active, targeting the offending immune cells for days to weeks after treatment.

INDICATIONS AND USES

Treatment of kidney transplant acute rejection in conjunction with concomitant immunosuppression.

Unlabeled uses:

Compassionate use in the treatment of acute rejection in bone marrow, heart, and liver transplants. Treatment of myelodysplastic syndrome (MDS).

CONTRAINDICATIONS

Patients with a known allergy to rabbit proteins, an acute viral illness, or a history of anaphylaxis during rabbit immunoglobulin administration.

PRECAUTIONS

Administered only under the direction of a physician experienced in immunosuppressive therapy and management of renal transplant patients in a facility with adequate laboratory and supportive medical resources. ■ Not considered effective for treating antibody-mediated (humoral) rejections. ■ Prolonged use or overdose in combination with other immunosuppressive agents may cause over-immunosuppression resulting in severe infections and may increase the incidence of lymphoma or posttransplant lymphoproliferative disease (PTLD) or other malignancies. Use of appropriate antiviral, antibacterial, antiprotozoal, and/or antifungal prophylaxis is recommended. In clinical trials, viral prophylaxis with ganciclovir infusion was used. ■ In clinical trials, anti-rabbit antibodies developed in 68% of patients. Controlled studies on repeat use of anti-thymocyte globulin in patients with anti-rabbit antibodies have not been conducted. Use caution if repeat courses are indicated; monitoring of lymphocyte count is recommended to ensure that T-cell depletion is achieved. ■ If anaphylaxis occurs during or after therapy, further administration of anti-thymocyte globulin is contraindicated.

Monitor:

Obtain baseline and monitor WBC and platelet counts during therapy. Thrombocytopenia or neutropenia may occur and are reversible following dose adjustment; see Dose Adjustments. ■ Close clinical observation is imperative. Monitor for side effects during and after infusion. Anaphylaxis has occurred; emergency equipment, medications, and supplies must be available. ■ Monitoring of the lymphocyte count (i.e., total lymphocyte count and T-cell counts [absolute and/or subset]) may help assess the degree of T-cell depletion. ■ Monitor carefully for signs of infection. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Imperative that all medications (especially immunosuppressants) be reviewed with physician. ■ Report any previous hypersensitivity/anaphylactic reaction. ■ Report acute viral infections immediately. ■ Promptly report chest pain, irregular or rapid heartbeat, shortness of breath, swelling of the face or throat, or wheezing during infusion of medication. ■ See Appendix D, p. 1311. ■ May be associated with an increased risk of malignancy.

Maternal/Child:

Category C: safety for use during pregnancy and breast-feeding not established. Safety and effectiveness for use in pediatric patients not established. Use only if clearly needed. ■ Has been used in pediatric patients in limited European studies and in the United States for compassionate use. Response similar to adults.

Elderly:

Specific information not available.

DRUG/LAB INTERACTIONS

Concurrent use with **immunosuppressants** (e.g., azathioprine, cyclosporine, mycophenolate, tacrolimus) may potentiate the immunosuppressive action of these agents; many transplant centers decrease maintenance immunosuppression therapy during the period of antibody therapy. ■ May **stimulate the production of antibodies,** which cross-react with rabbit immune globulins. ■ May interfere with **rabbit antibody-base immunoassays** and with **cross-match or panel-reactive antibody cytotoxicity assays.**

SIDE EFFECTS

Are dose-limiting. Abdominal pain, asthenia, diarrhea, dizziness, dyspnea, fever, headache, hyperkalemia, hypertension, infection, infusion reaction (e.g., chills and fever), leukopenia, malaise, nausea, pain, peripheral edema, tachycardia, and thrombocytopenia were reported frequently. Anaphylaxis has been reported.

Overdose:

Leukopenia or thrombocytopenia.

ANTIDOTE

Notify physician of all side effects. Most can be managed symptomatically. Manage leukopenia or thrombocytopenia during therapy or in overdose with dose reduction. Infusion reactions are managed with premedication and reduction in the rate of infusion. Treat infections aggressively; see Precautions. May require discontinuation of therapy. Discontinue infusion and/or therapy immediately if anaphylaxis occurs. Treat anaphylaxis immediately with epinephrine, diphenhydramine, oxygen, vasopressors (e.g., dopamine), corticosteroids, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

ANTIVENIN *(LATRODECTUS MACTANS)*

(an-tee-**VEN**-in **lat**-roh-**DEK**-tus **MACK**-tans)
Black Widow Spider Species Antivenin
Antivenin

USUAL DOSE

Pretreatment:

Testing for sensitivity to horse serum required before use. See Precautions for additional pretreatment requirements.

Antivenin:

Entire contents of 1 vial of antivenin (2.5 mL) is recommended for adults and pediatric patients. One vial is usually enough, but a second dose may be necessary in rare instances. Best results obtained if administered within 4 hours of envenomation.

PEDIATRIC DOSE

Same as adult dose. See Maternal/Child.

DILUTION

Each single dose (6,000 antivenin units) must be initially diluted with 2.5 mL SWFI (supplied). Keep needle in rubber stopper of antivenin and shake vial to dissolve contents completely. Must be further diluted in 10 to 50 mL NS for IV injection.

Storage:

Refrigerate unopened vials; do not freeze. Refrigerate reconstituted and/or diluted solution; discard in 6 hours.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

A single dose over a minimum of 15 minutes.

ACTIONS

Prepared from the blood serum of horses immunized against the venom of the black widow spider. One unit will neutralize one average mouse-lethal dose of black widow spider venom when both are injected simultaneously under lab conditions.

INDICATIONS AND USES

Treatment of patients with symptoms resulting from bites of black widow spiders *(Latrodectus mactans)* and similar spiders.

CONTRAINDICATIONS

Hypersensitivity to horse serum unless only treatment available for a life-threatening situation. Several techniques including preload of antihistamine and/or desensitization may be considered (see literature).

PRECAUTIONS

Read drug literature supplied with antivenin completely before use. Essential to evaluate symptoms and individual status of each patient. ■ Determine patient response to any previous injections of serum of any type and history of any hypersensitivity reactions. ■ Hospitalize patient if possible. ■ Muscle relaxants may be the initial treatment of choice in healthy individuals between 16 and 60. Antivenin use may be deferred while patient is observed. ■ Test every patient without exception for sensitivity to horse serum (1-mL vial of 1:10 dilution horse serum supplied). Conjunctival test and skin test recommended for maximum safety. Usually begin with the conjunctival test.

Conjunctival test: Instill 1 drop 1:10 horse serum into conjunctival sac for adults (1 drop 1:100 dilution for pediatric patients). Itching, redness, burning, and/or lacrimation within 10 minutes is a positive reaction. A drop of NS in the opposite eye is used as a control and should be asymptomatic. Reverse adverse effects of positive reaction with 1 drop epinephrine ophthalmic solution.

Skin test: Inject no more than 0.02 mL of 1:10 horse serum intradermally. In patients with a history of allergies, use a 1:100 solution. A similar injection of NS can be used as a control. Compare in 10 minutes. An urticarial wheal surrounded by a zone of erythema is a positive reaction.

■ A systemic reaction may occur even when both sensitivity tests are negative. ■ May be given IM. IV preferred in severe cases, if patient is in shock, or in pediatric patients under 12 years of age.

Monitor:

Supportive therapy is indicated. 10 mL of 10% calcium gluconate IV may control muscle pain. Morphine may be needed. Barbiturates or diazepam may be used for restlessness. Prolonged warm baths are helpful; corticosteroids have been used. ■ Observe patient constantly for respiratory paralysis. Can occur from toxin alone, and narcotics and sedatives may precipitate respiratory depression. ■ Observe for serum sickness for 8 to 12 days.

Patient Education:

Contact physician immediately for any S/S of a delayed hypersensitivity reaction (e.g., rash, pruritus, urticaria) after hospital discharge.

Maternal/Child:

Category C: use only if clearly needed. ■ Safety for use in breast-feeding not established. ■ Safety for use in pediatric patients not established, but there have been no adverse effects when used.

DRUG/LAB INTERACTIONS

Concomitant use of **antihistamines** may interfere with sensitivity tests. **Narcotics** and **sedatives** may precipitate respiratory depression.

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse. Serum sickness may occur. Usually appears in 7 to 12 days. Local pain, local erythema, and urticaria without systemic reaction can occur.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Treat anaphylaxis immediately. Epinephrine, diphenhydramine, oxygen, vasopressors (dopamine), corticosteroids, H_2 antagonists, and ventilation equipment must always be available. Resuscitate as necessary.

ANTIVENIN *(MICRURUS FULVIUS)*

(an-tee-**VEN**-in mi-**KROO**-rus **FUL**-vee-us)
North American Coral Snake Antivenin
Antivenin
pH 6.5 to 7.5

USUAL DOSE

Pretreatment:

Testing for sensitivity to horse serum required before use. See Precautions for additional pretreatment requirements.

Antivenin:

Entire contents of 3 to 5 vials (30 to 50 mL) is recommended depending on the nature and severity of envenomation. Up to 10 vials may be required if the snake's entire venom load was delivered by the bite. Best results obtained if administered within 4 hours of envenomation.

PEDIATRIC DOSE

Same as adult dose; not adjusted by weight of patient.

DILUTION

Each single vial must be diluted with 10 mL SW for injection. ***Do not use supplied diluent; do not use bacteriostatic water for injection (BWFI).*** Start an IV infusion of 250 to 500 mL NS. May be administered through the tubing of the free-flowing IV or added to the infusion solution after initial 2 mL given without adverse reaction.

Storage:

Store vials at CRT; do not freeze. Use reconstituted solution within 48 hours and diluted solution within 12 hours.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

Inject the first 1 to 2 mL over a minimum of 3 to 5 minutes. If no adverse reaction, give remaining initial dose at maximum rate of administration based on severity of envenomation and fluid tolerance appropriate for patient's body weight and condition (e.g., 250 to 500 mL over 30 minutes in a healthy adult, 100 mL in small pediatric patients followed by 4 mL/min).

ACTIONS

Prepared from the blood serum of horses immunized against the venom of specific coral snakes. Will neutralize the venom of *M. fulvius fulvius* (eastern coral snake) and *M. fulvius tenere* (Texas coral snake). Response should be rapid and dramatic.

INDICATIONS AND USES

Treatment of patients with symptoms resulting from the venom of *M. fulvius fulvius* (eastern coral snake) and *M. fulvius tenere* (Texas coral snake). ■ Not effective for *M. euryxanthus* (Arizona or Sonoran coral snake).

CONTRAINDICATIONS

Hypersensitivity to horse serum unless only treatment available for a life-threatening situation. Several techniques including preload of antihistamines and/or desensitization may be considered (see literature).

PRECAUTIONS

Read drug literature supplied with antivenin completely before use. ■ Essential to evaluate symptoms and individual status of each patient. ■ Determine patient response to any previous injections of serum of any type and history of any hypersensitivity reactions. ■ Immobilize victim. At a minimum, splint bitten extremity. Hospitalize patient if possible. ■ Test every patient without exception for sensitivity to horse serum (1-mL vial of 1:10 dilution horse serum supplied). Skin test recommended.

Skin test:

Inject 0.02 to 0.03 mL of a 1:10 dilution of horse serum in NS. In patients with a history of allergies use a 1:100 dilution. A similar injection of NS can be used as a control. Compare sites in 5 to 30 minutes. An urticarial wheal surrounded by a zone of erythema is a positive reaction. ■ A systemic reaction may occur even when both sensitivity tests are negative. ■ Tetanus prophylaxis indicated.

Monitor:

Observe patient constantly. Additional antivenin may be needed. Paralysis can occur within 2 to 2½ hours. Death from respiratory paralysis has occurred within 4 hours. Local tissue reaction does not reflect the amount of envenomation. Observe S/S to assess amount of toxin injected. Symptoms may begin in 1 hour or be delayed up to 18 hours. ■ Supportive therapy is indicated. Monitoring of electrolytes and continuous bladder drainage (hemoglobinuria) are recommended. Respiratory depressants (e.g., narcotics, sedatives) are contraindicated or used with extreme caution. Keep equipment for artificial ventilation immediately available.

Patient Education:

Contact physician immediately for any S/S of a delayed hypersensitivity reaction (e.g., rash, pruritus, urticaria) after hospital discharge.

Maternal/Child:

Category C: use only if clearly needed. ■ Safety for use during breast-feeding not established; problems not documented.

DRUG/LAB INTERACTIONS

Concomitant use of **antihistamines** may interfere with sensitivity tests. ■ **Narcotics and sedatives** may precipitate respiratory depression.

SIDE EFFECTS

Acute anaphylaxis with urticaria, respiratory distress, and vascular collapse. Serum sickness may occur. Usually appears in 7 to 12 days. Local pain, local erythema, and urticaria without systemic reaction can occur.

ANTIDOTE

Discontinue the drug and notify the physician of all side effects. Treat anaphylaxis immediately. Epinephrine and diphenhydramine, oxygen, vasopressors (dopamine), H_2 antagonists, and ventilation equipment must always be available. Resuscitate as necessary.

ANTIVENIN CROTALIDAE POLYVALENT IMMUNE FAB (OVINE)

(an-tee-**VEN**-in kro-**TAL**-ih-day pol-ih-**VAY**-lent im-**MYOUN** fab)
CroFab
Antivenin

USUAL DOSE

Contact a regional poison control center for individual treatment advice.

Pretreatment:

Obtain blood work before administration; see Contraindications, Precautions, and Monitor.

Premedication:

Premedication may be indicated for patients with allergies. Initiate as soon as possible after crotalid snakebite in patients who develop signs of progressive envenomation (e.g., worsening local injury, coagulation abnormality, or systemic signs of envenomation); see Monitor. Has been effective when given within 6 hours of snakebite.

Initial dose:

Skin testing for sensitivity to serum is not required. 4 to 6 vials is the recommended initial dose based on clinical experience. Adjust based on severity of envenomation when patient is initially assessed. Observe for up to 1 hour after initial dose administered. Desired outcome is complete control of the envenomation (i.e., complete arrest of local manifestations and return of coagulation tests and systemic signs to normal).

Repeat doses:

If control of symptoms is not accomplished by the initial dose, give an additional dose of 4 to 6 vials. This dose may be repeated until initial control of the envenomation syndrome has been achieved. After initial control has been established, give additional 2-vial doses every 6 hours for up to 18 hours (3 doses). Optimal dosing following the 18-hour scheduled dose has not been determined. Additional 2-vial doses may be given as directed by the treating physician, based on the patient's clinical response. Up to 18 vials have been given without any observed direct toxic effect. Scheduled dosing rather than PRN dosing may provide better control of envenomation symptoms caused by the continued leaking of venom from depot sites.

PEDIATRIC DOSE

Absolute venom dose following snakebite is expected to be the same in pediatric patients and adults; no dose adjustment for age is required. See Maternal/Child.

DOSE ADJUSTMENTS

No dose adjustments recommended.

DILUTION

Reconstitute each vial with 18 mL NS. Mix by continuous gentle swirling. Do not shake. Further dilute the contents of the reconstituted vials in 250 mL NS and mix by gently swirling.

Storage:

Refrigerate unopened vials; do not freeze. Reconstituted vials and diluted solution must be used within 4 hours.

COMPATIBILITY

Specific information not available. Administration through a separate line without mixing with other IV fluids or medications is suggested because of specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

Initiate infusion at a rate of 25 to 50 mL/hr for the first 10 minutes. Carefully observe for hypersensitivity reactions. If no adverse reaction occurs, increase rate to 250 mL/hr so that total dose is administered over 1 hour. Reduce rate of administration if infusion-related reactions occur (e.g., fever, low back pain, nausea, wheezing), and monitor closely.

ACTIONS

A venom-specific Fab fragment of immunoglobulin G (IgG) obtained from the blood of healthy sheep flocks immunized with one of four snake venoms; see Indications for specific venoms. To obtain the final product, the four different monospecific antivenins are mixed. Works by binding and neutralizing venom toxins, facilitating their redistribution away from target tissues and their elimination from the body. Half-life is estimated to be 12 to 23 hours.

INDICATIONS AND USES

Management of patients with North American Crotalid envenomation. The term *Crotalid* is used to describe the Crotalinae subfamily (formerly known as Crotalidae) of venomous snakes and includes rattlesnakes, copperheads, cottonmouths/water moccasins. Early use (within 6 hours) is advised to prevent clinical deterioration and the occurrence of systemic coagulation abnormalities.

CONTRAINDICATIONS

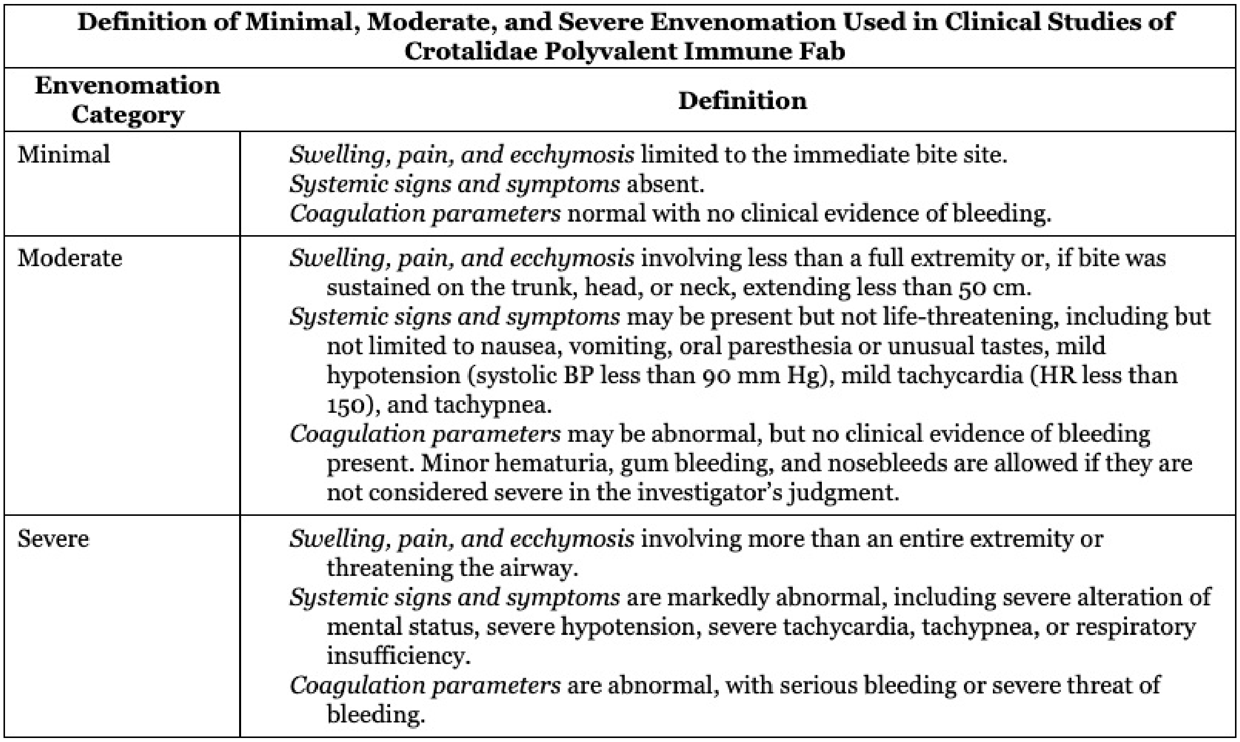
Known history of hypersensitivity to sheep, papaya, or papain unless benefits outweigh risks and appropriate management for anaphylactic reactions is readily available.

PRECAUTIONS

Usually administered in the hospital by or under the direction of the physician specialist with adequate diagnostic and treatment facilities readily available. ■ Patients with allergies to dust mites, latex, papain, chymopapain, other papaya extracts, the pineapple enzyme bromelain, or sheep protein may be at risk for a hypersensitivity reaction to this antivenin; see Contraindications; use caution. ■ Contains 0.03 mg of mercury per vial (ethyl mercury from thimerosal). Exposure from 18-vial dose is 0.6 mg of mercury. Definitive data not available; literature suggests that information related to methyl mercury toxicities may be applicable. ■ Recurrent coagulation abnormalities (e.g., decreased fibrinogen, decreased platelets, and elevated PT), defined as the return of a coagulation abnormality after it has been successfully treated with antivenin, were observed in patients who experienced coagulation abnormalities during their initial hospitalization and occurred in approximately one-half of patients studied. Crotalidae immune fab has a shorter persistence in the blood than crotalid venoms, which can leak from depot sites over a prolonged period of time; repeat dosing to prevent or treat such recurrence may be necessary. Optimal dosing to prevent recurrent coagulopathy has not been determined. ■ Use caution if a repeat course of treatment is required for a subsequent envenomation episode; crotalidae immune fab is a foreign protein and antibodies may develop, producing sensitivity.

Monitor:

Before antivenin is administered, draw adequate blood for baseline studies (e.g., type and cross-match, CBC, hematocrit, platelet count, PT, bleeding and coagulation times, BUN, electrolytes, and bilirubin). ■ Severity of envenomation is based on six body categories: cardiovascular, gastrointestinal, hematologic, local wound (e.g., pain, swelling, and ecchymosis), nervous system, and pulmonary effects. Specific parameters of minimal, moderate, and severe envenomation are outlined in the following chart.



Definition of Minimal, Moderate, and Severe Envenomation Used in Clinical Studies of Crotalidae Polyvalent Immune Fab

Envenomation Category	Definition
Minimal	*Swelling, pain, and ecchymosis* limited to the immediate bite site. *Systemic signs and symptoms* absent. *Coagulation parameters* normal with no clinical evidence of bleeding.
Moderate	*Swelling, pain, and ecchymosis* involving less than a full extremity or, if bite was sustained on the trunk, head, or neck, extending less than 50 cm. *Systemic signs and symptoms* may be present but not life-threatening, including but not limited to nausea, vomiting, oral paresthesia or unusual tastes, mild hypotension (systolic BP less than 90 mm Hg), mild tachycardia (HR less than 150), and tachypnea. *Coagulation parameters* may be abnormal, but no clinical evidence of bleeding present. Minor hematuria, gum bleeding, and nosebleeds are allowed if they are not considered severe in the investigator's judgment.
Severe	*Swelling, pain, and ecchymosis* involving more than an entire extremity or threatening the airway. *Systemic signs and symptoms* are markedly abnormal, including severe alteration of mental status, severe hypotension, severe tachycardia, tachypnea, or respiratory insufficiency. *Coagulation parameters* are abnormal, with serious bleeding or severe threat of bleeding.

■ Anaphylactic and anaphylactoid reactions, delayed hypersensitivity reactions (late serum reaction or serum sickness), and a possible febrile response to immune complexes formed by animal antibodies and neutralized venom components may occur. Observe all patients continuously for S/S of an acute hypersensitivity reaction (e.g., angioedema, bronchospasm with wheezing or cough, erythema, hypotension, pruritus, stridor, tachycardia, urticaria). ■ Follow-up monitoring is required for S/S of delayed hypersensitivity reactions or serum sickness (e.g., arthralgia, fever, myalgia, rash). ■ Monitor all vital signs at frequent intervals. Observe for signs of shock; treat with IV fluids, blood products, plasma expanders, vasopressors (e.g., dopamine) as indicated. ■ Keep emergency equipment available at all times, including oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment. ■ Initiate two IV lines as soon as possible—one to be used for supportive therapy, the other for antivenin and electrolytes. ■ If coagulation abnormalities occur, consider other disease processes associated with coagulation disorders (e.g., cancer, collagen disease, CHF, diarrhea, elevated temperature, hepatic disorder, hyperthyroidism, poor nutritional state, steatorrhea, vitamin K deficiency). ■ Monitor patients who experience coagulopathy due to snakebite during hospitalization for initial treatment for several weeks after discharge. Recurrent coagulopathy may persist for 1 to 2 weeks or more. Assess the need for retreatment and/or use of anticoagulant or antiplatelet agents. ■ Supportive measures to treat other manifestations of the snakebite (e.g., hypotension, pain, swelling, wound infection) should be implemented.

Patient Education:

Immediately report any S/S of delayed hypersensitivity reactions or serum sickness (e.g., pruritus, rash, or urticaria occurring after discharge). ■ Promptly report unusual bruising or bleeding (e.g., nosebleeds, excessive bleeding after toothbrushing or superficial injuries, blood in stools or urine, excessive menstrual bleeding, petechiae). May occur for up to 1 week or longer and indicate need for additional treatment.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Use caution; safety for use during breast-feeding not established. ■ Exposure to mercury has been associated with neurologic and renal toxicities. Developing fetuses and very young children are most susceptible and are at greater risk.

Elderly:

No specific studies on elderly patients.

DRUG/LAB INTERACTIONS

Studies have not been conducted.

SIDE EFFECTS

Pruritus, rash, and urticaria are frequent side effects. Anorexia, back pain, cellulitis, chest pain, chills, circumoral paresthesia, cough, delayed hypersensitivity reactions (late serum reaction or serum sickness), ecchymosis, febrile response to immune complexes formed by animal antibodies and neutralized venom components, general paresthesia, hypersensitivity reactions including anaphylaxis, hypotension, increased sputum, myalgia, nausea, nervousness, recurrent coagulopathy, and wound infection have occurred.

Post-Marketing:

Angioedema, bronchospasm, delayed hypersensitivity reactions (epigastric pressure, fever, hives, itching, rash), dizziness, dyspnea, erythema, failure to achieve initial control, headache, lip swelling, recurrent coagulopathy with medically significant bleeding, recurrent swelling (refractory to treatment), sweating, tachycardia, tachypnea, thrombocytopenia (refractory to treatment), tongue swelling, tracheal edema, treatment failure resulting in death, wheezing, worsening eyesight.

ANTIDOTE

Keep physician informed of all side effects and extent or progression of envenomation. Reduce the rate of administration if infusion-related reactions occur (e.g., fever, low back pain, nausea, wheezing). Monitor closely and discontinue antivenin if symptoms worsen or a hypersensitivity reaction occurs. Treat hypersensitivity reactions and/or anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment as indicated. Recurrent coagulopathy may require rehospitalization and additional antivenin administration. Resuscitate as necessary.

APREPITANT

(ap-**RE**-pi-tant)
Cinvanti, Aponvie
Antiemetic
Substance P/NK$_1$
Receptor antagonist

USUAL DOSE

Pretreatment:

See Maternal/Child.

Adult dose:

Highly emetogenic chemotherapy:

130 mg IV approximately 30 minutes before chemotherapy on Day 1.

Moderately emetotgenic chemotherapy:

100 mg IV 30 minutes before chemotherapy on Day 1.

DOSE ADJUSTMENTS

No dose adjustment indicated based on age, race, gender, renal status (including patients with ESRD undergoing dialysis), or mild to moderate hepatic insufficiency. Data in patients with severe hepatic insufficiency (Child-Pugh score >9) not available.

DILUTION

Supplied as an opaque, off-white to amber emulsion in a single-dose glass vial containing 130 mg/18 mL aprepitant.

Intravenous injection over 2 minutes:

Withdraw **18 mL for the 130-mg dose** or **14 mL for the 100-mg dose**. Do not dilute.

Intravenous infusion over 30 minutes:

Withdraw **18 mL for the 130-mg dose** or **14 mL for the 100-mg dose**. Transfer drug into a non-PVC infusion bag filled with 100 mL of NS or D5W. Gently invert the bag 4 to 5 times. Avoid shaking.

Filters:

Specific information not available.

Storage:

Before use, vials should be refrigerated at 2° to 8° C (36° to 46° F) or can remain at RT for up to 60 days. The diluted solution is stable at ambient RT for 6 hours in NS or for 12 hours in D5W or for up to 72 hours if stored under refrigeration in NS or D5W.

COMPATIBILITY

Manufacturer states, "Use only non-DEHP tubing and non-PVC infusion bags. Should not be mixed or reconstituted with solutions for which physical and chemical **compatibility** have not been established. Aprepitant for injection is **incompatible** with any solutions containing divalent cations (e.g., calcium or magnesium), including lactated Ringer's solution and Hartmann's solution."

RATE OF ADMINISTRATION

Injection:

A single dose as an injection over 2 minutes. Flush infusion line with NS before and after administration of aprepitant.

Infusion:

A single dose as an infusion equally distributed over 30 minutes. Use only non-DEHP tubing.

Complete the injection or infusion approximately 30 minutes before administration of chemotherapy.

ACTIONS

A selective high-affinity antagonist of human substance P/neurokinin$_1$ (NK$_1$) receptors. Has little or no affinity for 5-HT$_3$, dopamine, and corticosteroid receptors. Aprepitant inhibits emesis induced by cytotoxic chemotherapeutic agents, such as cisplatin, via central actions. Crosses the blood-brain barrier and occupies brain NK$_1$ receptors. Augments the antiemetic activity of the 5-HT$_3$-receptor antagonist ondansetron and the corticosteroid dexamethasone and inhibits both the acute and delayed phases of cisplatin-induced emesis. Highly protein bound. Undergoes extensive metabolism, primarily by CYP3A4 and to a lesser extent by CYP1A2 and CYP2C19. Eliminated primarily by metabolism; not renally excreted. Half-life is approximately 9 to 13 hours.

INDICATIONS AND USES

Used in combination with other antiemetic agents in adults for the prevention of acute and delayed nausea and vomiting associated with initial and repeat courses of highly emetogenic chemotherapy (HEC), including high-dose cisplatin, and for the prevention of nausea and vomiting associated with initial and repeat courses of moderately emetogenic chemotherapy (MEC).

Limitation of use:

Aprepitant has not been studied for the treatment of established nausea and vomiting.

CONTRAINDICATIONS

Hypersensitivity to any component of the product. ■ Concurrent use with pimozide (Orap); see Drug/Lab Interactions.

PRECAUTIONS

Aprepitant is a substrate, weak to moderate (dose dependent) inhibitor, and inducer of CYP3A4. Use with caution in patients receiving concomitant medications that are substrates, strong or moderate CYP3A4 inhibitors, or strong CYP3A4 inducers; see Drug/Lab Interactions. ■ Use with caution in patients with severe hepatic insufficiency (Child-Pugh score >9); see Dose Adjustments. ■ Serious hypersensitivity reactions, including anaphylaxis, have been observed during or soon after administration; see Monitor.

Monitor:

Monitor for S/S of a hypersensitivity reaction during and after the infusion (e.g., anaphylaxis, dyspnea, eye swelling, flushing, pruritus, wheezing). ■ Monitor IV site. ■ See Drug/Lab Interactions.

Patient Education:

Read FDA-approved patient information before starting therapy. ■ Discontinue use of aprepitant and promptly report S/S of a hypersensitivity reaction (e.g., difficulty breathing or swallowing, hives, itching, rash). ■ Efficacy of hormonal contraceptives may be reduced during and for 28 days after administration of the last dose of aprepitant. Alternative or backup methods of nonhormonal effective contraception (such as condoms or spermicides) should be used during treatment and for 1 month after the last dose of aprepitant. ■ Numerous drug interactions possible. A complete review of all prescription, nonprescription, and herbal products is required before each dose. ■ Patients on chronic warfarin therapy should have their INR checked in the 2-week period, particularly at 7 to 10 days, following initiation of regimen. ■ Report infusion site reactions.

Maternal/Child:

Avoid pregnancy due to alcohol content; may cause fetal harm, including CNS abnormalities, behavioral disorders, and impaired intellectual development. ■ Information on use during breast-feeding not available. Use caution. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to that seen in younger patients. Use caution when dosing; consider decreased hepatic, renal, or cardiac function and concomitant disease or other drug therapy.

DRUG/LAB INTERACTIONS

Aprepitant is a substrate, weak-to moderate (dose dependent) inhibitor, and inducer of CYP3A4. It is also an inducer of CYP2C9. ■ Use of aprepitant with other drugs that are CYP3A4 substrates may result in increased plasma concentration of the concomitant drug. ■ Concurrent use with **pimozide** is ***contraindicated***. Inhibition of CYP3A4 could result in elevated plasma concentrations of pimozide, potentially causing serious or life-threatening reactions such as QT prolongation; see Contraindications. ■ Efficacy of **hormonal contraceptives** may be reduced during and for 28 days after administration of the last dose of aprepitant (decreased estrogen and progestin exposure); see Patient Education. ■ Patients on chronic **warfarin** therapy should be closely monitored over a 2-week period, particularly at 7 to 10 days after initiation of aprepitant with each chemotherapy cycle. Coadministration may result in a clinically significant decrease in INR. ■ Aprepitant can increase plasma concentrations of **dexamethasone** and **methylprednisolone**. When given concurrently with aprepitant, reduce the dexamethasone and methylprednisolone PO doses by approximately 50% and the methylprednisolone IV dose by approximately 25%. (Dexamethasone doses listed in Usual Dose take the drug interaction into account.) ■ Coadministration of aprepitant with **chemotherapy agents metabolized by CYP3A4** (e.g., ifosfamide, vinblastine, and vincristine) should be done with caution and careful monitoring. ■ May increase plasma levels of **benzodiazepines**. Monitor for sedation. ■ Aprepitant is a CYP2C9 inducer. Has been shown to induce the metabolism of **CYP2C9 substrates** (e.g., tolbutamide, warfarin), thus decreasing plasma concentrations. Monitor patients receiving CYP2C9 substrates as indicated (e.g., plasma drug concentrations, therapeutic effect/efficacy, blood sugar control). ■ Avoid concomitant use with **moderate to strong CYP3A4 inhibitors** (e.g., clarithromycin, diltiazem, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, troleandomycin); may increase aprepitant plasma concentrations. ■ Coadministration with **strong CYP3A4 inducers** (e.g., carbamazepine, phenytoin, rifampin) may decrease aprepitant plasma concentrations and decrease efficacy. Avoid concurrent use. ■ Aprepitant is unlikely to interact with drugs that are **substrates for the P-glycoprotein transporter**. ■ Aprepitant did not have clinically important effects on the pharmacokinetics of **5-HT$_3$** antagonists (e.g., dolasetron, granisetron, ondansetron).

SIDE EFFECTS

The most common side effects reported include eructation, fatigue, headache, and infusion site reactions. Other reported side effects include abdominal pain or distention, acid reflux, acne, anemia, anxiety, bradycardia, cardiovascular disorder, chest discomfort, chills, cognitive disorder, conjunctivitis, constipation, cough, decreased neutrophil count, disorientation, dizziness, dream abnormality, dry mouth, dysgeusia, dysuria, edema, epigastric discomfort, euphoria, febrile neutropenia, flatulence, flushing, gait disturbance, gastroesophageal reflux disease, hematuria (microscopic), hyperglycemia, hyperhidrosis, hyponatremia, increased alkaline phosphatase, infusion site reactions, lethargy, muscle cramps or weakness, myalgia, nausea, neutropenic colitis, oily skin, palpitations, perforating duodenal ulcer, pharyngitis, photosensitivity, polydipsia, polyuria, postnasal drip, pruritus, rash, skin lesions, sneezing, somnolence, stomatitis, thirst, throat irritation, tinnitus, vomiting, and weight gain and/or weight loss.

Post-Marketing:

Hypersensitivity reactions (including anaphylaxis), pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria have been reported. Ifosfamide-induced neurotoxicity after aprepitant and ifosfamide coadministration has also been reported.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically. Discontinue aprepitant at the first sign of hypersensitivity. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines. Do not reinitiate aprepitant in patients who experience a severe hypersensitivity reaction. Aprepitant is not removed by hemodialysis.

ARGATROBAN

(ahr-**GAT**-troe-ban)
Anticoagulant
(direct thrombin inhibitor)
pH 3.2 to 7.5

USUAL DOSE

Pretreatment:

Discontinue all parenteral anticoagulants (e.g., heparin) and obtain baseline blood tests including an aPTT (prophylaxis or treatment) and ACT (PCI) before administration of argatroban; see Monitor.

Prophylaxis or treatment of thrombosis in patients with heparin-induced thrombocytopenia (HIT/HITTS):

Begin ***argatroban*** with an initial dose of 2 mcg/kg/min as a continuous infusion. Steady-state levels usually obtained within 1 to 3 hours. Check the aPTT in 2 hours and after any dose change. Adjust the mcg/kg/min dose (not to exceed 10 mcg/kg/min) as clinically indicated until the steady-state aPTT is 1.5 to 3 times the initial baseline value (not to exceed 100 seconds).

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI):

Aspirin

325 mg 2 to 24 hours before planned PCI was administered in studies. Begin ***argatroban*** with an initial infusion of 25 mcg/kg/min via a large-bore IV line. Next, administer a bolus of 350 mcg/kg over 3 to 5 minutes. 5 to 10 minutes after completion of bolus dose, check the ACT. The PCI may proceed if the ACT is greater than 300 seconds but less than 450 seconds. If ACT is less than 300 seconds, give an additional IV bolus of 150 mcg/kg, increase the infusion rate to 30 mcg/kg/min, and check the ACT in 5 to 10 minutes. If ACT is greater than 450 seconds, decrease the infusion rate to 15 mcg/kg/min and recheck the ACT in 5 to 10 minutes. When a therapeutic ACT has been achieved (between 300 and 450 seconds), the infusion dose in effect at the time the therapeutic ACT is achieved should be continued for the duration of the procedure. For situations outside these parameters, see Dose Adjustments. If anticoagulation is required after PCI, continue argatroban but lower infusion rate to 2 mcg/kg/min. Draw an aPTT in 2 hours and adjust the infusion rate as clinically indicated (not to exceed 10 mcg/kg/min) to reach an aPTT between 1.5 and 3 times baseline value (not to exceed 100 seconds); see All Situations in Monitor if transfer to oral anticoagulation is indicated.

DOSE ADJUSTMENTS

All situations:

No dose adjustment indicated in patients with impaired renal function, or based on age or gender. ■ In patients with hepatic impairment, initiate therapy at a lower dose and carefully titrate until the desired level of anticoagulation is reached. Achievement of steady-state aPTT levels may take longer and require more dose adjustments of argatroban in patients with hepatic impairment compared with patients with normal hepatic function.

Prophylaxis or treatment of thrombosis in patients with heparin-induced thrombocytopenia (HIT/HITTS):

Reduce initial dose to 0.5 mcg/kg/min in patients with moderate or severe hepatic impairment. There is a fourfold decrease in argatroban clearance in these patients; titrate dose carefully and monitor aPTT closely.

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI):

In case of dissection, impending abrupt closure, thrombus formation during the procedure, or inability to achieve or maintain an ACT over 300 seconds, additional bolus doses of 150 mcg/kg may be given and the infusion rate increased to 40 mcg/kg/min. Check the ACT after each additional bolus or change in rate of infusion. ■ In patients with hepatic impairment undergoing PCI, carefully titrate argatroban until desired level of anticoagulation is achieved. See Precautions for patients with clinically significant liver disease.

DILUTION

Available premixed at a final concentration of 1 mg/mL or as a 250-mg vial that must be diluted in 250 mL of NS, D5W, or LR to a concentration of 1 mg/mL. Mix by repeated inversion of the diluent bag for a minimum of 1 minute. Solution may initially be briefly hazy. Use of diluent at RT is recommended. Colder temperatures can slow down the rate of dissolution of precipitates. The vial should be discarded if the solution is cloudy or if an insoluble precipitate is noted. Do not expose prepared solutions to direct sunlight.

Storage:

Store vials in carton at CRT, protected from light and freezing. Diluted solution stable in ambient indoor light for 24 hours at 20° to 25° C (68° to 77° F). Light-resistant measures such as foil protection for IV lines are not necessary. Prepared solutions may be stable for up to 96 hours when protected from light and stored at 20° to 25° C (68° to 77° F) or refrigerated. Prepared solutions should not be exposed to direct sunlight. Store premixed bags in original carton at 20° to 25° C (68° to 77° F). Do not refrigerate or freeze. Protect from light.

COMPATIBILITY

Manufacturer states, “Should not be mixed with other drugs prior to dilution in a suitable IV fluid.” Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Prophylaxis or treatment of thrombosis in patients with heparin-induced thrombocytopenia (HIT/HITTS):

2 mcg/kg/min. See Usual Dose and/or Dose Adjustments as needed.

Anticoagulant in patients with or at risk for HIT/HITTS undergoing percutaneous coronary interventions (PCI):

See Usual Dose and/or Dose Adjustments for specific rates and criteria.

ACTIONS

An anticoagulant that is a highly selective synthetic direct thrombin inhibitor. It reversibly binds to the thrombin active site and exerts its anticoagulant effects by inhibiting thrombin-catalyzed or induced reactions, including fibrin formation; activation of coagulation factors V, VIII, and XIII and protein C; and platelet aggregation. Highly selective for thrombin with little or no effect on related serine proteases (trypsin, factor Xa, plasmin, and kallikrein). Inhibits both free and clot-bound thrombin. Does not require the cofactor antithrombin III for antithrombic activity. Produces a dose-dependent increase in aPTT, ACT, INR, PT, and TT. Anticoagulant effects are immediate. Steady-state levels of both drug and anticoagulant effect are usually attained within 1 to 3 hours and are maintained until the infusion is discontinued or the dose adjusted. Distribution is primarily in the extracellular fluid. Metabolized in the liver. Half-life range is 39 to 51 minutes. Excreted primarily in feces with some excretion in urine.

INDICATIONS AND USES

An anticoagulant for prophylaxis or treatment of thrombosis in patients with heparin-induced thrombocytopenia (HIT). ■ An anticoagulant in adult patients with or at risk for heparin-induced thrombocytopenia undergoing percutaneous coronary intervention (PCI). May be used in combination with aspirin.

CONTRAINDICATIONS

Hypersensitivity to argatroban or any of its components and patients with overt major bleeding.

PRECAUTIONS

All situations:

Hemorrhage can occur at any site. Intracranial and retroperitoneal hemorrhage has been reported. Use with extreme caution in disease states and other circumstances in which there is an increased danger of hemorrhage, including severe hypertension; immediately following lumbar puncture; spinal anesthesia; major surgery, especially involving the brain, spinal cord, or eye; hematologic conditions associated with increased bleeding tendencies such as congenital or acquired bleeding disorders and gastrointestinal lesions such as ulcerations. ■ Concomitant therapy with thrombolytic agents (e.g., alteplase [tPA], reteplase, streptokinase), antiplatelet agents, or other anticoagulants may increase the risk of bleeding, including life-threatening intracranial bleeding; see Drug/Lab Interactions. ■ Safety and effectiveness of argatroban for cardiac indications other than PCI in patients with HIT not established. ■ Use caution in patients with hepatic disease; argatroban clearance is decreased four-fold and elimination half-life is increased. Full reversal of anticoagulant effect may require longer than 4 hours. See Dose Adjustments.

PCI:

Avoid use of argatroban in PCI patients with clinically significant hepatic disease or AST/ALT levels equal to or greater than 3 times the upper limit of normal. These patients were not included in clinical trials.

Monitor:

All situations:

Obtain baseline and monitor platelet count, hemoglobin, hematocrit, and occult blood in stool in addition to required aPTT or ACT; see Usual Dose and specific parameters as follows. ■ Other coagulation tests (e.g., PT, INR, and TT) are affected by argatroban, but therapeutic ranges for these tests have not been identified. ■ Observe carefully for symptoms of a hemorrhagic event (e.g., unexplained fall in hematocrit, fall in hemoglobin, fall in BP, or any other unexplained symptom). ■ HIT is a serious, immune-mediated complication of heparin therapy that may result in subsequent venous and arterial thrombosis. Initial treatment of HIT is to discontinue all heparin, but patients still require anticoagulation for prevention and treatment of thromboembolic events. ■ Initiate oral anticoagulation with warfarin (Coumadin) when appropriate. Do not use a loading dose of warfarin; use the expected daily dose.

Monitor INR daily. Concurrent use with warfarin results in prolongation of the PT and INR beyond that produced by warfarin alone. With doses of argatroban up to 2 mcg/kg/min, argatroban can be discontinued when the INR is greater than 4 on combined therapy. After argatroban is discontinued, repeat the INR in 4 to 6 hours. If the INR is below the desired therapeutic range, resume the infusion of argatroban and repeat the procedure daily until the desired therapeutic range on warfarin alone is reached. See Drug/Lab Interactions. With doses of argatroban more than 2 mcg/kg/min the INR relationship is less predictable. Reduction of dose to 2 mcg/kg/min is recommended.

Prophylaxis or treatment of thrombosis:

Obtain a baseline aPTT before treatment begins. Repeat aPTT in 2 hours, after any dose adjustment, and as indicated to achieve desired target aPTT of 1.5 to 3 times baseline. ■ Repeated administration has been tolerated with no loss of anticoagulant activity and no evidence of neutralizing antibodies. No change in dose is required.

PCI:

Obtain baseline ACT before dosing; repeat ACT 5 to 10 minutes after bolus dosing, after a change in infusion rate, and at the end of the PCI procedure. Draw additional ACTs every 20 to 30 minutes during a prolonged procedure. ■ Follow standard procedures for maintenance and care of venous or arterial sheaths. In clinical studies, sheaths were removed no sooner than 2 hours after discontinuing argatroban and when ACT had decreased to less than 160 seconds. ■ See Dose Adjustments if anticoagulation is required after PCI.

Patient Education:

Review medication and medical history with physician. ■ Report all episodes of bleeding. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping. ■ Promptly report any S/S of hypersensitivity reaction (e.g., airway reactions, rash, dizziness).

Maternal/Child:

Use during pregnancy only if clearly needed. There are risks to the mother associated with untreated thrombosis in pregnancy and a risk of hemorrhage in the mother, fetus, and neonates associated with the use of anticoagulants. Monitor neonates for bleeding. ■ No data on the presence of argatroban in human milk or on its effects on milk production. ■ Safety and effectiveness for use in pediatric patients not established. ■ Has been used in a small number of pediatric patients with HIT or HITTS who require an alternative to heparin therapy. See package insert for dosing recommendations and monitoring parameters. Clearance was 50% lower in seriously ill pediatric patients compared with healthy adults.

Elderly:

Response similar to that in younger patients; efficacy is not affected by age. Safety analysis suggests that older patients tend to have an increased risk of events compared with younger patients; however, older patients have increased underlying conditions that may predispose them to adverse reactions.

DRUG/LAB INTERACTIONS

If argatroban is to be initiated after cessation of **heparin** therapy, allow sufficient time for heparin's effect on the aPTT to decrease before initiating argatroban therapy. ■ Drug interactions have not been demonstrated between argatroban and concomitantly administered **aspirin or acetaminophen.** ■ The safety and effectiveness of argatroban with thrombolytic agents and glycoprotein IIb/IIIa antagonists (e.g., eptifibatide, tirofiban) have not been established. ■ Risk of bleeding may be increased by any medicine that affects blood clotting, including **anticoagulants** (e.g., heparin, warfarin); **any medication that may cause hypoprothrombinemia, thrombocytopenia, or GI ulceration or bleeding** (e.g., selected antibiotics [e.g., cefotetan], aspirin, NSAIDs); **and/or any other medication that inhibits platelet aggregation** (e.g., clopidogrel, valproic acid). ■ Concurrent use with **warfarin** results in prolongation of the PT and INR beyond that produced by warfarin alone; see Monitor. The combination causes no further reduction in vitamin K dependent factor Xa than that seen with warfarin alone. Relationship between INR obtained on combined therapy and INR obtained on warfarin alone is dependent on both the dose of argatroban and the thromboplastin reagent used.

SIDE EFFECTS

All situations:

Bleeding is the most frequent adverse event. Hypersensitivity reactions (e.g., coughing, dyspnea, hypotension, rash) have been reported, most frequently in patients who also received streptokinase or contrast media.

Prophylaxis or treatment of thrombosis:

The most common side effects are cardiac arrest, diarrhea, dyspnea, fever, hypotension, and sepsis. Hemorrhagic events included brachial bleed, a decreased hemoglobin and hematocrit, GI bleed, groin bleed, GU bleed, hematuria, hemoptysis, intracranial bleed, limb and below-knee amputation stump, and multisystem hemorrhage and DIC. Abdominal pain, abnormal renal function, arrhythmias (e.g., atrial fibrillation, ventricular tachycardia), cerebrovascular disorder, coughing, infection, nausea, pain, pneumonia, UTI, and vomiting have occurred.

PCI:

The most common side effects are back pain, chest pain, headache, hypotension, nausea, and vomiting. Retroperitoneal and GI bleeding occurred in a few patients. Other minor bleeding included coronary arteries, a decreased hemoglobin and hematocrit, GI bleeding, GU bleeding, hematuria, groin, hemoptysis, and access site (venous or arterial). Abdominal pain, bradycardia, fever, and MI and other serious coronary events have occurred.

Overdose:

Symptoms of acute toxicity in animals included clonic convulsions, coma, loss of righting reflex, paralysis of hind limbs, and tremors.

ANTIDOTE

No specific antidote is available. Obtain aPTT, ACT, and/or other coagulation tests. Overdose with or without bleeding may be controlled by discontinuing argatroban or by decreasing the infusion dose; aPTT should return to baseline within 2 to 4 hours after discontinuation. Reversal may take longer in patients with hepatic impairment. If life-threatening bleeding develops and excessive plasma levels of argatroban are suspected, immediately stop argatroban infusion. Determine aPTT and hemoglobin, and prepare for blood transfusion as appropriate. Follow current guidelines for treatment of shock as indicated (fluid, vasopressors [e.g., dopamine], Trendelenburg position, plasma expanders [e.g., albumin]). Approximately 20% of argatroban may be cleared through a 4-hour dialysis session.

ARGININE HYDROCHLORIDE

(**AR**-jeh-neen hy-droh-**KLOR**-eyed)
R-Gene 10
Diagnostic agent
pH 5 to 6.5

USUAL DOSE

Pretreatment:

Specific testing requirements indicated; see Monitor.

Arginine:

30 Gm (300 mL) as a single dose under specific clinical conditions and procedures. Total dose should not exceed 30 Gm. Confirm serum electrolyte balance before administration.

PEDIATRIC DOSE

Weight 59 kg or less:

500 mg/kg (5 mL/kg) of body weight. Total dose should not exceed 30 gm. See Maternal/Child.

Weight 60 kg or more:

See Usual Dose.

DILUTION

Weight 60 kg or more:

Available as 10% solution (100 mg/mL) in 500-mL (300-mL fill) bottles ready for use as an IV infusion. Inspect each bottle; use only if clear and seal is intact. Expose rubber stopper by removing the tamperproof metal seal and disk. Close shut-off clamp and remove sterility protector from spike of the administration set. With bottle in an upright position, immediately insert the spike straight into the center of the stopper with a quick thrust. Do not twist; may cause stopper coring. Invert bottle to establish fluid level in the drip chamber and check for vacuum by observing rising filtered air bubbles. Discard if not clear or if vacuum is not present.

Weight 59 kg or less:

To avoid inadvertent delivery of an overdose, withdraw the weight-based dose from the 500-mL arginine bottle and place in a separate container for infusion.

Storage:

Store at CRT. Discard unused portions. Must be discarded within 4 hours of container penetration if stored at CRT or within 24 hours if refrigerated at 2° or 8° C (36° to 46° F). Do not use product that has been frozen.

COMPATIBILITY

Administration without mixing with other IV fluids or medications is suggested because of specific use. Stable in polypropylene syringes and in polyvinyl chloride (PVC) or ethylene vinyl acetate (EVA) infusion containers.

RATE OF ADMINISTRATION

A single dose evenly distributed over 30 minutes. Recommended dose must be infused in 30 minutes to ensure accurate test results. Use of an infusion pump is suggested. Excessive rates of infusion may cause local irritation and flushing, nausea, or vomiting.

ACTIONS

A diagnostic aid, it is an IV stimulant to the pituitary that often induces a pronounced rise in plasma level of human growth hormone (HGH) in normal individuals. This rise is diminished or absent in patients with impaired pituitary function.

INDICATIONS AND USES

IV stimulant to pituitary as a diagnostic aid. May be useful in detecting growth hormone deficiency in conditions such as panhypopituitarism, pituitary dwarfism, chromophobe adenoma, postsurgical craniopharyngioma, hypophysectomy, pituitary trauma, acromegaly, gigantism, and problems of growth or stature.

CONTRAINDICATIONS

Known hypersensitivity to any product ingredient.

PRECAUTIONS

Administer in a setting with facilities for monitoring the patient and responding to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ Confirm absolute patency of vein; hypertonic and acidic. Use of a large vein (e.g., anticubital) and confirmation of a patent catheter recommended. Observe site frequently. Extravasation can result in a severe burnlike reaction and/or tissue necrosis requiring surgical intervention. ■ False-positive or false-negative results approximately 30% of time. Cross-check or confirm result with a second arginine test or an insulin hypoglycemia test. Allow 1 day between each test. ■ Use extreme caution in pediatric patients; overdose has resulted in hyperchloremic metabolic acidosis, cerebral edema, and death. ■ High chloride content; use caution in patients with electrolyte imbalance. ■ Use caution in patients with renal disease. Metabolism results in nitrogen-containing products for excretion; consider temporary effect of an acute amino acid or nitrogen burden on the kidneys. ■ Basal and poststimulation levels of growth hormone are elevated in patients who are pregnant or are taking oral contraceptives.

Monitor:

Specific test procedure must be observed. ■ Schedule in morning; patient must be fasting overnight and have had a normal night's rest. ■ Maintain bed rest, fasting, and calming atmosphere from 30 minutes before infusion to completion of test process. ■ Draw blood samples from opposite arm of infusion 30 minutes before, at time infusion is begun, and every 30 minutes times 5. ■ Technician should promptly centrifuge and store all samples at −20° C (−4° F) until processed.

Maternal/Child:

Category B: pregnancy may cause a false-positive result. Do not use. ■ Safety for use during lactation not established. ■ Use extreme caution in pediatric patients; overdose has resulted in hyperchloremic metabolic acidosis, cerebral edema, and death.

Patient Education:

Promptly report S/S of a hypersensitivity reaction, delayed or immediate (e.g., hives, rash, shortness of breath or trouble breathing, swelling of eyelids, lips, or face). ■ Promptly report burning, pain, or swelling along the injection site.

Elderly:

Differences in response compared with younger adults have not been identified.

DRUG/LAB INTERACTIONS

Estrogens and estrogen-progestin combinations (e.g., oral contraceptives) may elevate growth hormone concentrations.

SIDE EFFECTS

Usually result from rate or hypertonicity of solution. Flushing, headache, local venous irritation, nausea, numbness, rash, tissue necrosis at site of infiltration, vomiting.

Overdose:

May cause transient metabolic acidosis with hyperventilation.

Post-Marketing:

Hypersensitivity reactions, including anaphylaxis and hematuria, have occurred during infusion or may be delayed 1 to 2 days. Extravasation requiring surgical intervention.

ANTIDOTE

Notify physician of all side effects. Discontinue drug and treat hypersensitivity reaction with diphenhydramine or epinephrine. If metabolic acidosis persists, calculation of deficit and use of an alkalizing agent (e.g., sodium bicarbonate) may be required. Discontinue drug if extravasation occurs, and notify physician to determine treatment. Resuscitate as necessary.

ARSENIC TRIOXIDE BBW

(**AR**-sen-ik try-**OKS**-ide)
Trisenox
Antineoplastic
pH 7.5 to 8.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. 12-lead ECG, serum electrolytes (calcium, magnesium, and potassium), serum creatinine, and potential changes in drug therapy required before beginning therapy. Gene pretesting may be indicated; see Indications and Uses, Monitor, and Precautions.

Differentiation syndrome prophylaxis:

For newly diagnosed low-risk acute promyelocytic leukemia, prednisone 0.5 mg/kg daily from Day 1 until the end of induction therapy with arsenic trioxide and tretinoin is recommended.

Newly diagnosed low-risk acute promyelocytic leukemia (APL):

Treatment course consists of 1 induction cycle and 4 consolidation cycles.

<table>
<tr><th colspan="9">Recommended Dose of Arsenic Trioxide in Combination With Tretinoin</th></tr>
<tr><th colspan="9">Induction (1 cycle)</th></tr>
<tr><td colspan="3">Arsenic trioxide
0.15 mg/kg once daily IV</td><td colspan="6">Until marrow remission but not to exceed 60 days</td></tr>
<tr><td colspan="3">Tretinoin
22.5 mg/M^2 twice daily PO</td><td colspan="6">Until marrow remission but not to exceed 60 days</td></tr>
<tr><th colspan="9">Consolidation (4 cycles)</th></tr>
<tr><th></th><th>Week 1</th><th>Week 2</th><th>Week 3</th><th>Week 4</th><th>Week 5</th><th>Week 6</th><th>Week 7</th><th>Week 8</th></tr>
<tr><td>Arsenic trioxide
0.15 mg/kg once daily IV</td><td>Days 1-5</td><td>Days 1-5</td><td>Days 1-5</td><td>Days 1-5</td><td>—</td><td>—</td><td>—</td><td>—</td></tr>
<tr><td>Tretinoin[a]
22.5 mg/M^2 twice daily PO</td><td>Days 1-7</td><td>Days 1-7</td><td>—</td><td>—</td><td>Days[b] 1-7</td><td>Days[b] 1-7</td><td>—</td><td>—</td></tr>
</table>

[a] Round tretinoin to the nearest 10-mg increment.

[b] Tretinoin omitted during the 4th cycle of consolidation.

Relapsed or refractory APL:

A treatment course consists of 1 induction cycle and 1 consolidation cycle.

Induction schedule:

0.15 mg/kg of body weight IV daily as an infusion until bone marrow remission or up to a maximum of 60 days.

Consolidation schedule:

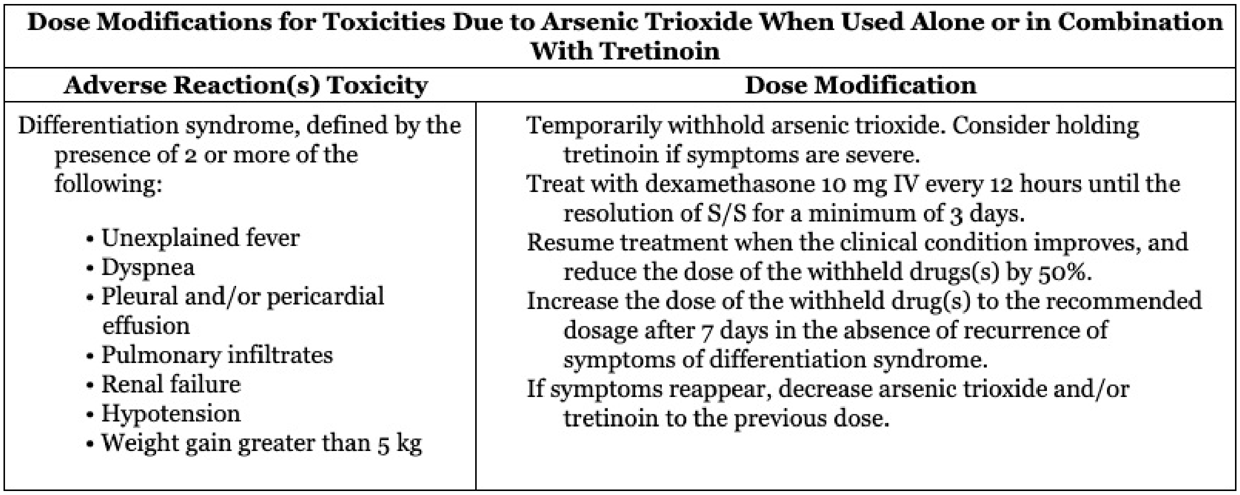
Begin 3 to 6 weeks after completion of induction therapy. 0.15 mg/kg IV daily for 25 doses over a period of up to 5 weeks.

PEDIATRIC DOSE

Relapsed or refractory APL in pediatric patients from 5 to 16 years of age:

See Usual Dose. See Maternal/Child.

DOSE ADJUSTMENTS



Dose Modifications for Toxicities Due to Arsenic Trioxide When Used Alone or in Combination With Tretinoin

Adverse Reaction(s) Toxicity	Dose Modification
Differentiation syndrome, defined by the presence of 2 or more of the following: • Unexplained fever • Dyspnea • Pleural and/or pericardial effusion • Pulmonary infiltrates • Renal failure • Hypotension • Weight gain greater than 5 kg	Temporarily withhold arsenic trioxide. Consider holding tretinoin if symptoms are severe. Treat with dexamethasone 10 mg IV every 12 hours until the resolution of S/S for a minimum of 3 days. Resume treatment when the clinical condition improves, and reduce the dose of the withheld drugs(s) by 50%. Increase the dose of the withheld drug(s) to the recommended dosage after 7 days in the absence of recurrence of symptoms of differentiation syndrome. If symptoms reappear, decrease arsenic trioxide and/or tretinoin to the previous dose.

QTc prolongation greater than 450 msec for men or greater than 460 msec for women	Withhold treatment with arsenic trioxide and any medication known to prolong the QTc interval. Replace electrolytes. After the QTc normalizes, resume treatment with arsenic trioxide at a 50% reduced dose (0.075 mg/kg once daily) for 7 days. If the 50% reduced dose is tolerated for 7 days (in the absence of QTc prolongation), increase the dose of arsenic trioxide to 0.11 mg/kg once daily for 7 days. The dose of arsenic trioxide can be increased to 0.15 mg/kg in the absence of QTc prolongation during that 14-day dose-escalation period.
Hepatotoxicity, defined by 1 or more of the following: • Total bilirubin (TB) greater than 3 × the upper limit of normal (ULN) • Aspartate aminotransferase (AST) greater than 5 × ULN • Alkaline phosphatase (AP) greater than 5 × ULN	Withhold treatment with arsenic trioxide and/or tretinoin. Resume treatment at a 50% reduced dose of the withheld drug(s) when TB is less than 1.5 × ULN and AP/AST are less than 3 × ULN. Increase the dose of the withheld drug(s) back to the recommended dosage after 7 days on the reduced dose in the absence of worsening of hepatotoxicity. Discontinue the withheld drug(s) permanently if hepatotoxicity recurs.
Other severe or life-threatening (Grade 3-4) nonhematologic reactions	Temporarily withhold arsenic trioxide and tretinoin. When the adverse reaction resolves to no more than mild (Grade 1), resume arsenic trioxide and tretinoin reduced by 2 dose levels (see the following chart).
Moderate (Grade 2) nonhematologic reactions	Reduce the dose of arsenic trioxide and/or tretinoin by 1 dose level (see the following chart).
Leukocytosis (WBC count greater than 10 Gi/L)	Administer hydroxyurea. Hydroxyurea may be discontinued when the WBC declines below 10 Gi/L.
Myelosuppression, defined by 1 or more of the following: • Absolute neutrophil count less than 1 Gi/L • Platelets less than 50 Gi/L lasting more than 5 weeks	Consider reducing the dose of arsenic trioxide and tretinoin by 1 dose level (see the following chart). If myelosuppression lasts 50 days or more or occurs on 2 consecutive cycles, assess a marrow aspirate for remission status. In the case of molecular remission, resume arsenic trioxide and tretinoin at 1 dose lower (see the following chart).

Dose Reduction Levels for Hematologic and Nonhematologic Toxicities

Dose Level	Arsenic Trioxide (mg/kg IV once daily)	Tretinoin[a] (mg/M^2 PO twice daily)
Starting level	0.15 mg/kg	22.5 mg/M^2
−1	0.11 mg/kg	18.75 mg/M^2
−2	0.1 mg/kg	12.5 mg/M^2
−3	0.075 mg/kg	10 mg/M^2

[a] Tretinoin is rounded to the nearest 10-mg increment.

■ Patients with severe renal impairment (CrCl less than 30 mL/min) or severe hepatic impairment (Child-Pugh Class C) should be closely monitored for toxicity. Dose reduction may be indicated. ■ Use in dialysis has not been studied.

DILUTION

Specific techniques required; see Precautions.

Vial contains 12 mg/6 mL (2 mg/mL) of a clear, colorless solution. Dilute each daily dose with 100 to 250 mL D5W or NS immediately after withdrawal from the vial and give as an infusion.

Storage:

Store vials at CRT. Do not freeze. Do not use beyond expiration date. Discard unused portions of each vial; contains no preservatives. Diluted solutions are stable for 24 hours at RT and 48 hours if refrigerated.

COMPATIBILITY

Manufacturer states, “Do not mix arsenic trioxide with other medications.”

RATE OF ADMINISTRATION

A single daily dose as an infusion over 2 hours. May be extended up to 4 hours if acute vasomotor reactions are observed (e.g., flushing, hypertension, hypotension, pallor). May be given through a peripheral vein; a central venous catheter is not required.

ACTIONS

An antineoplastic agent. Mechanism of action not understood. May cause morphologic changes and DNA fragmentation in selected promyelocytic leukemia cells and damage or degrade selected fusion proteins. Widely distributed. Arsenic trioxide is immediately hydrolyzed to its active form, arsenious acid. Metabolized in the liver (not by the cytochrome P_{450} family of isoenzymes). Elimination half-life is 10 to 14 hours. Excreted in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

In combination with tretinoin for treatment of adults with newly-diagnosed low-risk acute promyelocytic leukemia (APL) whose APL is characterized by the presence of the t(15;17) translocation or PML/RAR-alpha gene expression. ■ Induction of remission and consolidation in patients with APL who are refractory to, or have relapsed from, retinoid and anthracycline chemotherapy, and whose APL is characterized by the presence of the t(15;17) translocation or PML/RAR-alpha gene expression.

Unlabeled uses:

APL, including intermediate- or high-risk disease in adults and APL in pediatric patients.

CONTRAINDICATIONS

Known hypersensitivity to arsenic.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of a physician experienced in the management of patients with acute leukemia, with facilities for monitoring the patient and responding to any medical emergency. ■ Differentiation syndrome, which may be life-threatening or fatal, has been observed in patients with APL. Symptoms may include acute respiratory distress, dyspnea, fever, hypotension, peripheral edema, pleural or pericardial effusions, pulmonary infiltrates, weight gain, and renal, hepatic, or multiorgan dysfunction with or without leukocytosis. See Dose Adjustments, Monitor, and Antidote. ■ Can cause QT interval prolongation and complete atrioventricular block. QT prolongation can lead to torsades de pointes, which can be fatal. Do not administer arsenic trioxide to patients with ventricular arrhythmia or prolonged QTcF. Risk of torsades de pointes is increased by extent of QT prolongation, concomitant administration of QT prolonging drugs, a history of torsades de pointes, pre-existing QT interval prolongation, congestive heart failure, administration of potassium-wasting diuretics, or other conditions that result in hypokalemia or hypomagnesemia; see Drug/Lab Interactions. QT prolongation was observed between 1 and 5 weeks after infusion and returned toward baseline by the end of 8 weeks after infusions were complete. ■ Serious encephalopathy, including Wernicke's encephalopathy, has occurred. Wernicke's encephalopathy is a neurologic emergency. ■ Use caution in patients with impaired renal function; exposure may be increased. Monitor patients with severe renal impairment (CrCl less than 30 mL/min) closely for toxicity; dose reduction may be required. ■ Use with caution in patients with impaired hepatic function. Data are limited. Monitor patients with severe hepatic impairment (Child-Pugh Class C) closely for toxicity. ■ Hepatotoxicity (e.g., elevations of AST, alkaline phosphatase, and serum bilirubin) has occurred in patients treated with arsenic trioxide in combination with tretinoin. These elevations may resolve with temporary discontinuation of arsenic trioxide and/or tretinoin; see Dose Adjustments and Monitor. ■ Moderately emetogenic. Consider administration of antiemetics to prevent nausea and vomiting and improve patient comfort. ■ Arsenic trioxide is a human carcinogen. Development of second primary malignancies may occur.

Monitor:

Before initiating therapy: Confirmation of eligibility for treatment (presence of the t(15;17) translocation or PML/RAR-alpha gene expression) may be indicated. Obtain baseline 12-lead ECG to assess the QTc interval, CBC with differential, platelet count, coagulation studies (e.g., PT/INR), serum electrolytes (e.g., calcium, magnesium, and potassium), and serum creatinine. Correct pre-existing electrolyte abnormalities and, if possible, discontinue drugs that are known to prolong the QT interval; see Drug/Lab Interactions. If it is not possible to discontinue the interacting drug, perform cardiac monitoring frequently. ***During induction therapy:*** Monitor blood counts, coagulation studies, and chemistries at least two to three times weekly through recovery. Monitor at least weekly during consolidation. May be indicated more frequently. Keep potassium concentrations above 4 mEq/dL and magnesium concentrations above 1.8 mg/dL. ■ Monitor ECG weekly and more frequently in unstable patients. No data on the effect of arsenic trioxide on the QT interval during the infusion. If the QT interval is greater than 500 msec at any time during therapy, reassess the patient, correct concomitant risk factors, and consider risk/benefit of continuing versus suspending arsenic trioxide; see Dose Adjustments. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for signs of APL differentiation syndrome (e.g., abnormal chest auscultatory findings or radiographic abnormalities, dyspnea, weight gain, and unexplained fever). Has occurred as early as Day 1 of induction to as late as the second month of induction therapy. If differentiation syndrome is suspected, irrespective of the leukocyte count, begin immediate treatment with hemodynamic monitoring and high-dose steroids (e.g., dexamethasone 10 mg IV twice daily); continue until S/S have resolved for at least 3 days. Temporary discontinuation of arsenic trioxide treatment may be required; see Dose Adjustments. ■ Monitor for neurologic symptoms (e.g., ataxia, cognitive deficits, confusion, decreased level of consciousness, ocular motor dysfunction, seizures, and visual symptoms) and nutritional status while receiving treatment. If encephalopathy is suspected, immediately initiate parenteral thiamine; monitor until symptoms resolve or improve and thiamine levels normalize. ■ Test thiamine levels in patients at risk for thiamine deficiency (e.g., chronic alcohol use, concomitant use of furosemide, malabsorption, and nutritional deficiency). ■ Administer parenteral thiamine in patients with or at risk for thiamine deficiency. ■ Monitor for the development of second primary malignancies. ■ Moderately emetogenic. Consider prophylactic administration of antiemetics to prevent nausea and vomiting. ■ See Precautions.

Patient Education:

Avoid pregnancy; can cause fetal harm. Use of effective birth control advised for females during treatment with arsenic trioxide and for 6 months after the final dose and for males with partners of reproductive potential during treatment and for 3 months after the final dose. Notify physician immediately if a pregnancy is suspected. ■ May impair fertility in males of reproductive potential. ■ Report cognitive deficits, confusion, decreased level of consciousness, dizziness, dyspnea, fainting, fever, impaired balance/coordination, neurologic symptoms, rapid or irregular heartbeat, seizures, visual impairment, and weight gain immediately. ■ Review all prescription and nonprescription drugs with your physician. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Can cause fetal harm. Effective birth control required; see Patient Education. ■ Discontinue breast-feeding during treatment and for 2 weeks after the final dose. ■ Safety and effectiveness for use in combination with tretinoin in pediatric patients has not been established. ■ Limited clinical data for pediatric use in monotherapy. In one study, five patients ranging in age from 5 to 16 years were included in clinical studies. A literature review included an additional 17 patients 4 to 21 years of age treated for relapsed or refractory APL. No differences in safety and effectiveness were observed by age. ■ Safety and effectiveness for pediatric patients under 4 years of age not established.

Elderly:

Arsenic trioxide in combination with tretinoin: Lower survival rates have been observed in elderly patients; monitor frequently during this combination treatment. ***Arsenic trioxide monotherapy:*** Response similar to that in younger patients. ■ Monitor renal function closely.

DRUG/LAB INTERACTIONS

Concurrent use with **other drugs that prolong the QT interval, including antiarrhythmics** (e.g., amiodarone, disopyramide, ibutilide, mexiletine, procainamide, quinidine), **antihistamines, azole antifungals** (e.g., itraconazole), **fluoroquinolones** (e.g., levofloxacin), **macrolide antibiotics** (e.g., azithromycin), **phenothiazines** (e.g., thioridazine), **and tricyclic antidepressants** (e.g., amitriptyline, imipramine) may cause torsades de pointes and could be fatal. Discontinue or replace with an alternative drug that does not prolong the QT/QTc interval. Monitor ECGs more frequently in patients when it is not feasible to avoid concomitant use. ■ Concurrent use with drugs that may cause hypokalemia or other electrolyte abnormalities (e.g., **amphotericin B, diuretics** [e.g., furosemide]) may increase the risk of hypokalemia and cardiac arrhythmias. Monitor electrolytes more frequently with concomitant use. ■ Risk of serious hepatotoxicity may be increased with concurrent use of **other hepatotoxic agents** (e.g., azathioprine, isoniazid, methotrexate, retinoids, sulfasalazine), particularly when arsenic trioxide is given in combination with tretinoin. Discontinue or replace with an alternative drug that does not cause hepatotoxicity. Monitor liver function tests more frequently in patients when it is not feasible to avoid concomitant use.

SIDE EFFECTS

Arsenic trioxide in combination with tretinoin:

Cardiac dysfunction (Grade 3-4), gastrointestinal toxicity (Grade 3-4), hepatic toxicity (Grade 3-4), hypercholesterolemia, hypertriglyceridemia, infection and fever of unknown origin, leukocytosis, neurotoxicity (mostly reversible peripheral neuropathy), neutropenia for more than 15 days (Grade 3-4), QT prolongation, thrombocytopenia for more than 15 days (Grade 3-4) have been reported. Side effects associated with arsenic trioxide monotherapy may also occur.

Arsenic trioxide monotherapy:

Abdominal pain, anemia, chest pain, cough, diarrhea, dizziness, dyspnea, edema (facial), fatigue, headache, hyperglycemia, hyperkalemia, hypertension, hypokalemia, hypomagnesemia, hypotension, hypoxia, itching, leukocytosis, nausea, neutropenia (may be febrile), palpitations, pleural effusion, rash, thrombocytopenia, URI, and vomiting. Numerous other side effects have been reported (see literature).

Adverse events rated Grade 3 or 4 on the Common Terminology Criteria for Adverse Events (CTCAE) were common. APL differentiation syndrome, atrial arrhythmias, hepatotoxicity, hyperglycemia, hyperleukocytosis, QT interval 500 msec or more (with or without torsades de pointes) also occurred.

Overdose:

Acute arsenic toxicity (e.g., confusion, convulsions, and muscle weakness).

Post-Marketing:

Encephalopathy, pancytopenia, peripheral neuropathy, posterior reversible encephalopathy syndrome, ventricular extrasystoles, tachycardia associated with QT prolongation, and Wernicke's encephalopathy. Numerous other side effects have been reported post-marketing; see literature.

ANTIDOTE

Keep physician informed of all side effects. Those classified as average will usually be treated symptomatically. Major side effects may be fatal and require aggressive treatment as well as temporarily withholding or discontinuing arsenic trioxide and/or tretinoin. In all situations, monitor electrolytes; maintain potassium and magnesium within prescribed limits. Interrupt treatment with arsenic trioxide and treat APL differentiation syndrome immediately with high-dose steroids (dexamethasone 10 mg IV twice daily) until S/S have resolved for at least 3 days. Temporarily discontinue arsenic trioxide for QT prolongation 500 msec or more; see Dose Adjustments for recommendations, and promptly treat any serious or symptomatic arrhythmia (e.g., conduction abnormalities, VT, torsades de pointes). Discontinue therapy and treat acute arsenic intoxication. If Wernicke's encephalopathy is suspected, immediately interrupt arsenic trioxide and initiate parenteral thiamine; monitor until symptoms resolve or improve and thiamine levels normalize. Chelation therapy should be considered. Dimercaprol (BAL) 3 mg/kg IM every 4 hours until immediate life-threatening toxicity subsides followed with penicillamine 250 mg PO up to four times a day (approximately 1 Gm/day) has been utilized. Hyperleukocytosis may warrant treatment with hydroxyurea.

ASCORBIC ACID

(a-**SKOR**-bik **AS**-id)
Sodium Ascorbate, Vitamin C
Nutritional supplement (vitamin)
pH 5.5 to 7

USUAL DOSE

Usually administered orally. When oral administration is not feasible or when malabsorption is suspected, ascorbic acid may be administered IM, IV, or SC.

Up to 6 Gm/24 hr has been given without toxicity.

Nutritional protection:

70 to 150 mg daily. 100 to 200 mg daily may be required during chronic dialysis.

Prevention or treatment of scurvy:

300 to 1,000 mg daily. Another source suggests 100 to 250 mg 1 to 3 times daily. Give for a minimum of several days; up to 2 to 3 weeks may be indicated.

Enhance wound healing:

300 to 500 mg daily for 7 to 10 days.

Burns:

1 to 2 Gm daily.

Other conditions in which the need for ascorbic acid is increased:

Three to five times the daily optimum allowances appears to be adequate.

PEDIATRIC DOSE

Nutritional protection:

30 mg daily. Another source suggests 35 to 100 mg/day. ***Premature infants*** may require 75 to 100 mg daily.

Prevention or treatment of scurvy:

100 to 300 mg/24 hr. May be given once daily or divided into two doses (twice daily). Give for a minimum of several days; up to 2 to 3 weeks may be indicated.

DILUTION

Pressure may develop within a vial during storage. Use care when withdrawing and/or relieve pressure by first inserting a sterile, empty syringe into vial to release pressure. Dilution in a large volume of NS or Dextrose solution is recommended. Soluble in the more commonly used solutions, such as D5W, D5NS, NS, LR, Ringer’s injection, or sodium lactate injection. Slight coloration does not affect the medication.

Storage:

Protect from freezing and from light. Storage requirements are product specific and range from 2° to 8° C (36° to 46° F) to below 25° C (77° F).

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Infusion:

Administer at ordered rate for standard infusion (e.g., over 4 to 8 hours). Avoid too-rapid injection.

ACTIONS

This water-soluble vitamin is necessary for the formation of collagen in all fibrous tissue, carbohydrate metabolism, connective tissue repair, maintenance of intracellular stability of blood vessels, and many other body functions. Not stored in the body. Daily requirements must be met. Completely utilized; excess is excreted unchanged in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prevention and treatment of vitamin C deficiency, which may lead to scurvy. ■ Give pre-op and post-op to enhance wound healing. ■ Prolonged IV therapy. ■ Increased vitamin requirements or replacement therapy in severe burns, extensive injuries, and severe infections. ■ Prematurity. ■ Deficient intestinal absorption of water-soluble vitamins. ■ Prolonged or wasting diseases. ■ Hemovascular disorders and delayed fracture and wound healing require increased intake.

CONTRAINDICATIONS

There are no absolute contraindications.

PRECAUTIONS

Vitamin C is better absorbed and utilized by IM injection. ■ Use caution in cardiac patients. ■ Patients with diabetes, patients prone to recurrent renal calculi, patients undergoing stool occult blood tests, and patients on sodium-restricted diets or anticoagulant therapy should not take excessive doses of ascorbic acid over extended periods; use caution. ■ May contain sulfites; use caution in allergic individuals. ■ Some products may contain aluminum; use with caution in neonates and in patients with renal insufficiency.

Monitor:

Increased urinary excretion is diagnostic for vitamin C saturation. ■ Continue curative doses until clinical symptoms subside or urinary saturation occurs.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Use caution during breast-feeding; high dose may adversely affect fetus.

DRUG/LAB INTERACTIONS

Potentiates **oral contraceptives and ferrous iron absorption.** ■ May antagonize **anticoagulants.** ■ 2 Gm/day will lower urine pH and will cause reabsorption of **acidic drugs and** crystallization with **sulfonamides.** ■ Limited evidence suggests ascorbic acid may influence the intensity and duration of action of **bishydroxycoumarin**. ■ **Can alter numerous test results;** must be individually evaluated. ■ Patients with diabetes taking more than 500 mg of ascorbic acid daily may obtain false readings of urinary glucose tests. ■ May cause false-negative occult blood in stool if ascorbic acid is ingested within 48 to 72 hours before testing occurs.

SIDE EFFECTS

Occur only with too-rapid injection: temporary dizziness or faintness. Diarrhea or renal calculi may occur with large doses.

ANTIDOTE

Discontinue administration temporarily. Resume administration at a decreased rate. If side effects persist, discontinue drug and notify the physician.

ATEZOLIZUMAB BBW

(**A**-te-zoe-**LIZ**-ue-mab)
Tecentriq
Monoclonal antibody (anti-PD-L1)
Antineoplastic agent
pH 5.8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting required in selected patients and baseline studies indicated; see Precautions and Monitor.

Locally advanced or metastatic urothelial carcinoma or previously treated non–small-cell lung cancer (as a single agent):

840 mg every 2 weeks, or 1,200 mg every 3 weeks, or 1,680 mg every 4 weeks. Administered as an intravenous infusion over 60 minutes until disease progression or unacceptable toxicity. For all dosages, if the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes.

First-line treatment of metastatic nonsquamous non–small-cell lung cancer:

1,200 mg every 3 weeks administered as an IV infusion over 60 minutes followed by bevacizumab, paclitaxel, and carboplatin on Day 1 of each 21-day cycle for a maximum of 4 to 6 cycles of chemotherapy. If the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes. Following completion of 4 to 6 cycles of paclitaxel and carboplatin, and if bevacizumab is discontinued, the recommended dose of atezolizumab is 840 mg every 2 weeks, 1,200 mg every 3 weeks, or 1,680 mg every 4 weeks administered as an intravenous infusion over 60 minutes (administer subsequent infusions over 30 minutes if 60 minutes was tolerated) until disease progression or unacceptable toxicity. Refer to prescribing information for bevacizumab, paclitaxel, and carboplatin for recommended dosing information.

Locally advanced or metastatic triple-negative breast cancer (TNBC):

840 mg administered as an IV infusion over 60 minutes, followed by 100 mg/M^2 paclitaxel protein-bound. For each 28-day cycle, atezolizumab is administered on Days 1

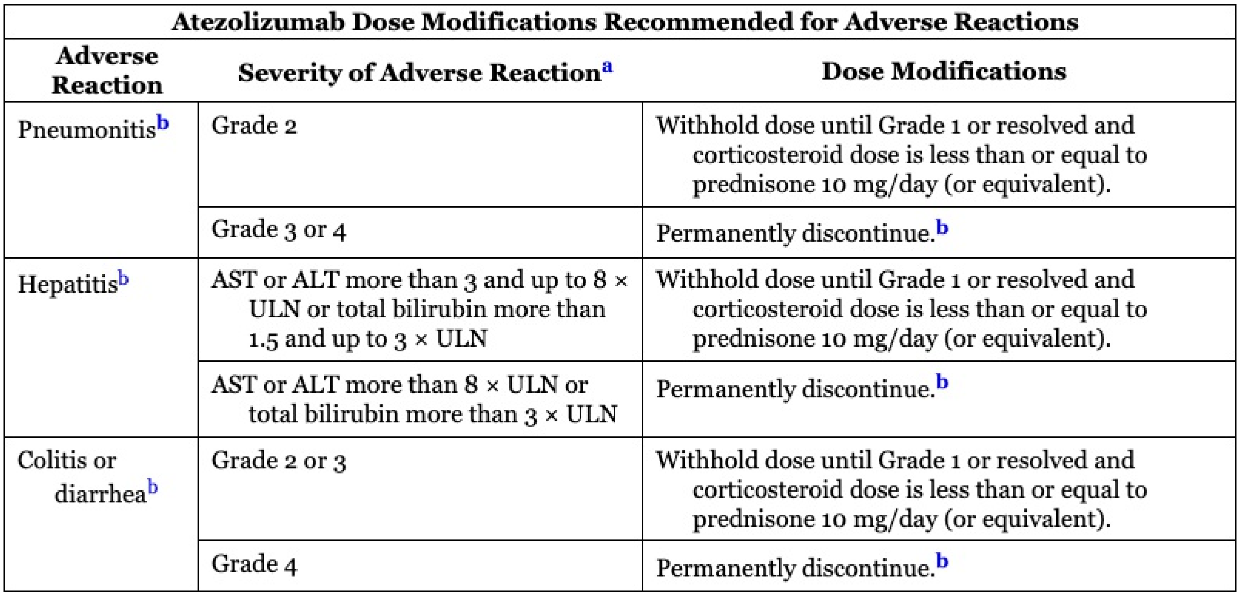
and 15, and paclitaxel protein-bound is administered on Days 1, 8, and 15 until disease progression or unacceptable toxicity. Atezolizumab and paclitaxel protein-bound may be discontinued for toxicity independently of each other. If the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes. Refer to prescribing information for paclitaxel protein-bound before initiation.

Small-cell lung cancer (SCLC):

1,200 mg administered intravenously over 60 minutes every 3 weeks until disease progression or unacceptable toxicity. When administered in combination with carboplatin and etoposide, administer atezolizumab before chemotherapy when given on the same day. Refer to the prescribing information for the chemotherapy agents administered in combination with atezolizumab for recommended dosing information. Following completion of 4 cycles of carboplatin and etoposide, the recommended dose of atezolizumab is 840 mg every 2 weeks, or 1,200 mg every 3 weeks, or 1,680 mg every 4 weeks. Administer until disease progression or unacceptable toxicity. If the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes

DOSE ADJUSTMENTS

No dose reductions are recommended. Recommended dose modifications for adverse reactions are provided in the following chart.



Atezolizumab Dose Modifications Recommended for Adverse Reactions

Adverse Reaction	Severity of Adverse Reaction[a]	Dose Modifications
Pneumonitis[b]	Grade 2	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than or equal to prednisone 10 mg/day (or equivalent).
	Grade 3 or 4	Permanently discontinue.[b]
Hepatitis[b]	AST or ALT more than 3 and up to 8 × ULN or total bilirubin more than 1.5 and up to 3 × ULN	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than or equal to prednisone 10 mg/day (or equivalent).
	AST or ALT more than 8 × ULN or total bilirubin more than 3 × ULN	Permanently discontinue.[b]
Colitis or diarrhea[b]	Grade 2 or 3	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than or equal to prednisone 10 mg/day (or equivalent).
	Grade 4	Permanently discontinue.[b]

Endocrinopathies (including but not limited to hypophysitis, adrenal insufficiency, hyperthyroidism, and type 1 diabetes mellitus)[b]	Grade 2, 3, or 4	Withhold dose until Grade 1 or resolved and clinically stable on hormone replacement therapy.
Other immune-mediated adverse reactions involving a major organ[b]	Grade 3	Withhold dose until Grade 1 or resolved and corticosteroid dose is less than or equal to prednisone 10 mg/day (or equivalent).
	Grade 4	Permanently discontinue.[b]
Infections[b]	Grade 3 or 4	Withhold dose until Grade 1 or resolved.
Infusion-related reactions[b]	Grade 1 or 2	Interrupt or slow the rate of infusion.
	Grade 3 or 4	Permanently discontinue.[b]
Persistent Grade 2 or 3 adverse reaction (excluding endocrinopathies)	Grade 2 or 3 adverse reaction that does not recover to Grade 0 or 1 within 12 weeks after last atezolizumab dose	Permanently discontinue.[b]
Inability to taper corticosteroid	Inability to reduce to less than or equal to prednisone 10 mg/day (or equivalent) within 12 weeks after last atezolizumab dose	Permanently discontinue.[b]
Recurrent Grade 3 or 4 adverse reaction	Recurrent Grade 3 or 4 (severe or life-threatening) adverse reaction	Permanently discontinue.[b]

[a] National Cancer Institute Common Terminology Criteria for Adverse Events (NCI CTCAE) version 4.

[b] See Precautions, Monitor, and Antidote.

- No dose adjustments are recommended for patients with mild or moderate renal impairment or mild hepatic impairment.

DILUTION

Atezolizumab is a colorless to slightly yellow solution available in a single-dose vial containing either 840 mg/14 mL or 1,200 mg/20 mL (60 mg/mL). Discard the vial if the solution is cloudy or discolored or if visible particles are observed. ***Do not shake the vial.*** Select the appropriate vial(s) based on the prescribed dose. Withdraw the required volume of atezolizumab from the vial(s) and transfer into a 250-mL polyvinyl chloride (PVC), polyethylene (PE), or polyolefin (PO) infusion bag containing NS. Dilute only with NS. Mix diluted solution by gentle inversion. ***Do not shake.***

Filters:

May use with or without a sterile, nonpyrogenic, low–protein-binding, in-line filter (pore size of 0.2-0.22 micron).

Storage:

Store at 2° to 8° C (36° to 46° F) in original carton to protect from light. Does not contain a preservative. Do not freeze or shake. Administer immediately once prepared. If diluted solution is not used immediately, it can be stored at RT for up to 6 hours (from time of preparation and including infusion time) or refrigerated at 2° to 8° C (36° to 46° F) for no more than 24 hours. Discard empty vials of atezolizumab.

COMPATIBILITY

Manufacturer states, "Do not coadminister other drugs through the same intravenous line." **Compatible** only with NS.

RATE OF ADMINISTRATION

Do not administer as an intravenous push or bolus.

A single dose as an infusion equally distributed over 60 minutes through an IV line with or without a sterile, nonpyrogenic, low–protein binding, in-line filter (pore size of 0.2-0.22 micron). If the first infusion is tolerated, all subsequent infusions may be delivered over 30 minutes. Interrupt or slow the rate of infusion for mild or moderate infusion reactions. Permanently discontinue if a Grade 3 or 4 infusion reaction occurs.

ACTIONS

Atezolizumab is a programmed death ligand-1 (PD-L1) blocking antibody. PD-L1 may be expressed on tumor cells and/or tumor-infiltrating immune cells and can contribute to inhibition of the antitumor immune response in the tumor microenvironment. Binding of PD-L1 to the PD-1 and B7.1 receptors found on T-cells and antigen-presenting cells suppresses cytotoxic T-cell activity, T-cell proliferation, and cytokine production. Atezolizumab is a Fc-engineered, humanized, monoclonal antibody that binds to PD-L1 and blocks its interactions with the PD-1 and B7.1 receptors. This releases the PD-L1/PD-1–mediated inhibition of the immune response, including activation of the antitumor immune response without inducing antibody-dependent cellular cytotoxicity. In syngeneic mouse tumor models, blocking PD-L1 activity resulted in decreased tumor growth. Terminal half-life is approximately 27 days. The population PK analysis suggests a steady state is obtained after 6 to 9 weeks (2 to 3) cycles of repeated dosing.

INDICATIONS AND USES

Treatment of adult patients with locally advanced or metastatic urothelial carcinoma (MUC) who (1) are not eligible for cisplatin-containing chemotherapy and whose tumors express PD-L1 (PD-L1–stained tumor-infiltrating immune cells [IC] covering 5% or more of the tumor area) as determined by an FDA-approved test, or (2) are not eligible for any platinum-containing chemotherapy regardless of PD-L1 status, or (3) have disease progression during or following platinum-containing chemotherapy or within 12 months of neoadjuvant or adjuvant chemotherapy. This indication is approved under accelerated approval based on tumor response rate and durability of response. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trial(s). ■ Treatment of adult patients with metastatic NSCLC who have disease progression during or following platinum-containing chemotherapy. Given as a single agent. Patients with *EGFR* or *ALK* genomic tumor aberrations should have disease progression on FDA-approved therapy for NSCLC harboring these aberrations before receiving atezolizumab. ■ First-line treatment of adult patients with metastatic nonsquamous non–small-cell lung cancer (Nsq NSCLC) with no EGFR or ALK genomic tumor aberrations. Given in combination with bevacizumab, paclitaxel, and carboplatin. ■ Treatment of adult patients with unresectable locally advanced or metastatic triple-negative breast cancer (TNBC) whose tumor expresses PD-L1 (PD-L1 stained tumor-infiltrating immune cells [IC] of any intensity covering ≥1% of the tumor area) as determined by an FDA-approved test. Given in combination with paclitaxel protein-bound. This indication is approved under accelerated approval based on progression-free survival. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trial(s). ■ First-line treatment of adult patients with extensive-stage small-cell lung cancer (ES-SCLC). Given in combination with carboplatin and etoposide.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Immune-mediated pneumonitis or interstitial lung disease (defined as requiring the use of systemic corticosteroids), including fatal cases, have occurred with atezolizumab. ■ Liver test abnormalities and immune-mediated hepatitis (defined as requiring the use of systemic corticosteroids), including fatal cases, has occurred with atezolizumab. ■ Immune-mediated colitis or diarrhea (defined as requiring the use of systemic corticosteroids) has occurred with atezolizumab. ■ Immune-related endocrinopathies, including adrenal insufficiency, hypophysitis/hypopituitarism, type 1 diabetes mellitus (including diabetic ketoacidosis), and thyroid disorders, have occurred with atezolizumab. ■ Atezolizumab can cause other severe and fatal immune-mediated adverse reactions that may involve any organ system (e.g., cardiac, dermatologic, gastrointestinal, hematologic, musculoskeletal, neurologic, ophthalmologic, renal, or vascular). May occur during or after treatment with atezolizumab; see Monitor. ■ Severe infections, including fatal cases, have been reported. Urinary tract infections were more common in patients with urothelial carcinoma; pneumonia was more common in patients with NSCLC. ■ Severe, sometimes life-threatening infusion-related reactions have been reported; see Rate of Administration. ■ See Dose Adjustments and Monitor for criteria to withhold or discontinue atezolizumab therapy and for medications for treatment of atezolizumab-related adverse reactions. ■ Effect of severe renal impairment or moderate or severe hepatic impairment on pharmacokinetics of atezolizumab is unknown. ■ A protein substance; has the potential for immunogenicity.

Monitor:

Select cisplatin-ineligible patients with previously untreated locally advanced or metastatic urothelial carcinoma for treatment with atezolizumab based on the PD-L1 expression on tumor-infiltrating immune cells. Select patients with locally advanced or metastatic triple-negative breast cancer for treatment with atezolizumab in combination with paclitaxel protein-bound based on the PD-L1 expression of tumor-infiltrating immune cells. For information on FDA-approved tests, see http://www.fda.gov/companiondiagnostics. ■ Obtain baseline liver function studies and thyroid function tests and monitor periodically during treatment. ■ For any suspected immune-mediated adverse reaction, ensure adequate evaluation to confirm etiology or to exclude other causes. ■ Monitor for S/S of **pneumonitis** (e.g., chest pain, new or worsening cough, shortness of breath). Evaluate with radiographic imaging. Administer steroids (1 to 2 mg/kg/day prednisone equivalents, followed by corticosteroid taper) for Grade 2 or greater pneumonitis. Withhold or permanently discontinue atezolizumab based on the severity. See Dose Adjustments. ■ Monitor patients for S/S of **hepatitis** (e.g., easy bruising or bleeding, jaundice, lethargy, pain on right side of the abdomen, severe nausea or vomiting). Monitor AST, ALT, and bilirubin periodically during and after treatment with atezolizumab. Administer corticosteroids (1 to 2 mg/kg/day prednisone equivalents, followed by corticosteroid taper) for Grade 2 or higher elevations in AST, ALT, or bilirubin. Interrupt or permanently discontinue atezolizumab based on severity; see Dose Adjustments. ■ Monitor patients for S/S of **diarrhea or colitis**. Withhold atezolizumab treatment for Grade 2 or 3 diarrhea or colitis. If symptoms persist for longer than 5 days or recur, administer 1 to 2 mg/kg prednisone or equivalent per day followed by corticosteroid taper. Interrupt atezolizumab or permanently discontinue based on the severity. See Dose Adjustments. ■ Monitor for S/S of **hypophysitis** (e.g., fatigue, headache, dizziness or fainting, changes in vision, or low levels of hormones produced by the pituitary [ACTH], thyroid stimulating hormone [TSH], follicle-stimulating hormone [FSH], luteinizing hormone [LH], growth hormone [GH], or prolactin). For Grade 2 or higher hypophysitis, administer corticosteroids (1 to 2 mg/kg/day prednisone equivalents, followed by corticosteroid taper) and hormone replacement as clinically indicated. Interrupt therapy based on severity; see Dose Adjustments. ■ Monitor for S/S of immune-mediated **thyroid disorders**. Monitor thyroid function tests periodically during treatment. Initiate hormone replacement therapy or medical management of hyperthyroidism as clinically indicated. Continue atezolizumab for hypothyroidism and interrupt for hyperthyroidism based on the severity; see Dose Adjustments. ■ Monitor for S/S of **adrenal insufficiency** (e.g., fatigue, nausea, vomiting, hypotension, hyponatremia, hyperkalemia, low cortisol). For Grade 2 or higher adrenal insufficiency, administer prednisone 1 to 2 mg/kg/day or equivalent followed by a taper and hormone replacement as clinically indicated. Interrupt atezolizumab based on the severity; see Dose Adjustments. ■ Monitor for S/S of **diabetes mellitus** (hyperglycemia, increased thirst, urination). Monitor serum glucose and, if indicated, initiate treatment with insulin for type 1 diabetes mellitus. Interrupt atezolizumab based on the severity; see Dose Adjustments. ■ Monitor for S/S of **other immune-mediated adverse reactions** (e.g., cardiac [myocarditis], dermatologic [bullous dermatitis, pemphigoid, erythema multiforme, Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN)], gastrointestinal [pancreatitis, including increases in serum amylase or lipase levels], general [systemic inflammatory response syndrome, histiocytic necrotizing lymphadenitis], hematologic [autoimmune hemolytic anemia, immune thrombocytopenic purpura], musculoskeletal [myositis, rhabdomyolysis], neurologic [Guillain-Barré syndrome, myasthenia syndrome/myasthenia gravis, demyelination, immune-related meningoencephalitis, aseptic meningitis, encephalitis, facial and abducens nerve paresis, polymyalgia rheumatica, autoimmune neuropathy, and Vogt-Koyanagi-Harada syndrome], ophthalmologic [uveitis, iritis], renal [nephrotic syndrome, nephritis], vascular [vasculitis]). For suspected Grade 2 immune-mediated adverse reactions, exclude other causes and initiate corticosteroids as clinically indicated. For severe (Grade 3 or 4) adverse reactions, administer prednisone 1 to 2 mg/kg/day or equivalents, followed by a taper. Interrupt or permanently discontinue atezolizumab based on the severity of the reaction; see Dose Adjustments. If uveitis occurs in combination with other immune-mediated adverse reactions, evaluate for Vogt-Koyanagi-Harada syndrome, which has been observed with other products in this class and may require treatment with systemic steroids to reduce the risk of permanent vision loss. ■ Monitor for S/S of **infection**. Initiate antibiotic therapy in patients with suspected or confirmed bacterial infections; see Dose Adjustments. ■ Monitor for S/S of **infusion-related reactions** (e.g., chills, fever, flushing, hypotension, hypoxemia, pruritus, rash, rigors, wheezing). Interrupt, slow the rate of infusion, or permanently discontinue based on the severity. For Grade 1 or 2 infusion-related reactions, consider using premedications with subsequent doses.

Patient Education:

Review FDA-approved Medication Guide. ■ Verify pregnancy status in females of reproductive potential before initiating atezolizumab. ■ Effective contraception required during treatment and for at least 5 months after the last dose of atezolizumab. ■ Advise patients to contact their health care provider immediately for S/S of infusion-related reactions (e.g., chills, feeling faint, fever, flushing, hypoxemia, pruritus, rigors, wheezing). ■ Some side effects may require corticosteroid treatment and interruption or discontinuation of atezolizumab. ■ Promptly report S/S of pneumonitis (e.g., new or worsening cough, chest pain, shortness of breath). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on right side of abdomen, severe nausea or vomiting). ■ Promptly report S/S of colitis (e.g., blood or mucus in stools, diarrhea, severe abdominal pain). ■ Promptly report S/S of hypophysitis, hyperthyroidism, hypothyroidism, adrenal insufficiency, or type 1 diabetes mellitus, including diabetic ketoacidosis. S/S may include constipation, dizziness or fainting, extreme tiredness, feeling cold, hair loss, headaches that will not go away, increased thirst or urination, and weight gain or weight loss. ■ Numerous side effects are possible. Report any side effect or change in condition to health care provider. ■ Keeping scheduled appointments for blood work or other laboratory tests is imperative. ■ May impair fertility in females of reproductive potential.

Maternal/Child:

Based on its mechanism of action, atezolizumab can cause fetal harm when administered to a pregnant woman. ■ Do not breast-feed while taking atezolizumab and for at least 5 months after receiving the last dose. ■ Safety and effectiveness for use in pediatric patients have not been established.

Elderly:

No overall difference in safety or efficacy has been observed between younger patients and patients 65 years of age and older.

DRUG/LAB INTERACTIONS

The drug interaction potential of atezolizumab is unknown.

SIDE EFFECTS

The most common adverse reactions with atezolizumab as a single agent are cough, decreased appetite, dyspnea, fatigue/asthenia, and nausea. The most common adverse reactions when used in combination with other antineoplastic drugs in patients with NSCLC and SCLC were alopecia, constipation, decreased appetite, diarrhea, fatigue/asthenia, and nausea. The most common adverse reactions when used in combination with paclitaxel protein-bound were alopecia, anemia, constipation, cough, decreased appetite, diarrhea, fatigue, headache, nausea, neutropenia, peripheral neuropathies, and vomiting.

Urothelial carcinoma:

The most common Grade 3 or 4 adverse reactions reported include ALT increase, anemia, blood creatinine increase, decreased appetite, diarrhea, fatigue, hyponatremia, hypotension, intestinal obstruction, pain (back/neck), renal failure, sepsis, and urinary tract infection. Serious adverse reactions included acute kidney injury, diarrhea, intestinal obstruction, renal failure, and sepsis. Other adverse reactions included cough, peripheral edema, infusion reactions, pruritus, rash, respiratory tract infection, upper respiratory tract infection, venous thromboembolism, and vomiting. Diarrhea/colitis, dyspnea, fatigue, hypersensitivity, and sepsis led to discontinuation. Deaths resulted from cardiac arrest, intestinal obstruction, myocardial infarction, pneumonitis, respiratory distress or failure, and sepsis.

NSCLC:

The most common adverse reactions reported include cough, decreased appetite, dyspnea, and fatigue. The most common Grade 3 or 4 adverse reactions include diarrhea, decreased appetite, dehydration, fatigue/asthenia, hypertension, febrile neutropenia, nausea, pneumonia, and pulmonary embolism. Deaths resulted from aortic dissection, aspiration pneumonia, cardiac arrest, cerebrovascular accident, chronic obstructive pulmonary disease, febrile neutropenia, hemoptysis, intestinal ischemia, intestinal obstruction, intracranial hemorrhage, pneumonia, pulmonary embolism, and pulmonary hemorrhage.

TNBC:

The most common Grade 3 or 4 adverse reactions included anemia, decreased neutrophil count, fatigue, hypokalemia, increased AST, neutropenia, peripheral neuropathies, and pneumonia. The most frequent serious adverse reactions were dyspnea, fever, pneumonia, and urinary tract infection. The most common adverse reaction leading to discontinuation was peripheral neuropathy. Fatal adverse reactions included aspiration, autoimmune hepatitis, mucosal inflammation, pneumonia, pulmonary embolism, and septic shock. Numerous laboratory abnormalities occurred. See prescribing information for complete list.

SCLC:

The most common Grade 3 or 4 adverse reactions were asthenia, diarrhea, fatigue/asthenia, febrile neutropenia, infusion-related reactions, and pneumonia. Fatal adverse reactions included neutropenia, pneumonia, and respiratory failure. Other adverse reactions included alopecia, anemia, constipation, decreased appetite, increased ALT, nausea, leukopenia, lymphopenia, thrombocytopenia, and vomiting.

See prescribing information for complete list of adverse reactions based on diagnosis.

See Precautions for additional serious adverse reactions that have been reported with the administration of atezolizumab.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Interrupt or slow the rate of administration in patients with mild or moderate infusion reactions. See Dose Adjustments and Monitor for when to interrupt or permanently discontinue atezolizumab and for treatment specifics for immune-mediated adverse reactions. Treat hypersensitivity/infusion reactions as needed (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids). There is no information on overdose with atezolizumab.

ATRACURIUM BESYLATE BBW

(ah-trah-**KYOUR**-ee-um **BES**-ih-layt)
Atracurium Besylate PF, Tracrium
Neuromuscular blocking agent (nondepolarizing)
Anesthesia adjunct
pH 3.25 to 3.65

USUAL DOSE

Adjunct to general anesthesia for adults and pediatric patients over 2 years of age:

Must be individualized, depending on previous drugs administered and degree and length of muscle relaxation required. 0.4 to 0.5 mg/kg of body weight initially as an IV bolus. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. To maintain muscle relaxation during prolonged surgical procedures, a maintenance dose of 0.08 to 0.1 mg/kg may be given as a bolus injection. The first maintenance dose is usually required 20 to 45 minutes after the initial bolus and may be repeated every 15 to 25 minutes. Higher maintenance doses (up to 0.2 mg/kg) permit maintenance dosing at longer intervals. Repeated doses have no cumulative effect if recovery is allowed to begin before administration. A peripheral nerve stimulator is used to determine the beginning symptoms of neuromuscular blockade reversal. May alternately be given as a continuous IV infusion. An initial infusion rate of 9 to 10 mcg/kg/min may be required to counteract the spontaneous recovery of neuromuscular function. Thereafter a rate of 5 to 9 mcg/kg/min may be adequate. Rates as low as 2 or as high as 15 mcg/kg/min may be required. Repeated doses have no cumulative effect if recovery is allowed to begin before administration.

Adjunct to general anesthesia for infants and children 1 month to 2 years of age:

0.3 to 0.4 mg/kg for infants and children under halothane anesthesia. See Usual Dose for maintenance dose; may be required more frequently.

Support of intubated, mechanically ventilated, adult ICU patients:

An initial infusion rate of 11 to 13 mcg/kg/min (range 4.5 to 29.5) provides adequate neuromuscular blockade. Published reports describe a wide interpatient variability in dosing requirements, and requirements may increase or decrease with time. Readministration of a bolus dose may be necessary to re-establish neuromuscular block following recovery and before reinstitution of the infusion.

DOSE ADJUSTMENTS

Reduce dose by one third (0.25 to 0.35 mg/kg) if isoflurane or enflurane are used as general anesthetics. ■ Reduce dose to 0.3 to 0.4 mg/kg in patients with a history of cardiovascular disease, a history suggesting greater risk of histamine release (allergies), or following succinylcholine administration. Succinylcholine must show signs of wearing off before atracurium is given. Use caution. ■ Reduce maintenance dose by one-half when hypothermia is induced (e.g., during cardiac bypass). Consider reduced doses in patients with neuromuscular disease, severe electrolyte disorders, or carcinomatosis in which potentiation of neuromuscular block or difficulties with reversal have been demonstrated. ■ No dose adjustment required in patients with renal disease. ■ See Drug/Lab Interactions.

DILUTION

Initial IV bolus may be given undiluted. Maintenance dose for anesthesia and mechanical ventilation support may be further diluted in NS, D5W, or D5NS and given as a continuous infusion titrated to symptoms of neuromuscular blockade reversal. 20 mg (2 mL) diluted in 98 mL yields 200 mcg/mL (0.2 mg/mL). 50 mg (5 mL) diluted in 95 mL yields 500 mcg/mL (0.5 mg/mL).

Storage:

Refrigerate in carton at 2° to 8° C (36° to 46° F), protect from light, and do not freeze. If removed to RT, it must be used within 14 days even if re-refrigerated. Diluted solution stable for 24 hours refrigerated or at room temperature; discard after 24 hours.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

In adults or pediatric patients, adjust infusion rate according to clinical assessment of the patient’s response. Use of a peripheral nerve stimulator is recommended.

Adjunct to general anesthesia:

Initial IV bolus over 30 to 60 seconds.

Maintenance dose:

In the 200 mcg/mL dilution, 5 mcg/kg/min will be delivered by a rate of 0.025 mL/kg/min or 1.75 mL/min for a 70-kg patient (105 mL/hr). Adjust rate to specific dose desired. Drug literature has additional rate calculations.

Mechanical ventilation support in ICU:

See Usual Dose for specific rates and criteria.

ACTIONS

A nondepolarizing skeletal muscle relaxant. A less potent histamine releaser than metocurine. Causes paralysis by interfering with neural transmission at the myoneural junction. Onset of action is dose dependent. Produces maximum neuromuscular blockade within 3 to 5 minutes and lasts about 25 minutes. When infusion is discontinued, some recovery occurs within 30 minutes. Recovery to 75% averages 60 minutes (range 32 to 108 minutes). It may be several hours before complete recovery occurs. Excreted as metabolites in bile and urine. Crosses the placental barrier.

INDICATIONS AND USES

Adjunctive to general anesthesia to facilitate endotracheal intubation and to relax skeletal muscles during surgery or mechanical ventilation.

CONTRAINDICATIONS

Known hypersensitivity to atracurium.

PRECAUTIONS

For IV use only. ■ Administered by or under the observation of the anesthesiologist. Appropriate emergency drugs and equipment for monitoring the patient and responding to any medical emergency must be readily available. ■ Use extreme caution in patients with significant cardiovascular disease or a history of allergies or allergic reaction. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Myasthenia gravis and other neuromuscular diseases increase sensitivity to drug. Can cause critical reactions. ■ Respiratory depression with propofol (Diprivan) or morphine may be preferred in some patients requiring mechanical ventilation. ■ Bradycardia is fairly common since atracurium will not counteract the bradycardia produced by many anesthetic agents or vagal stimulation. ■ Acid-base and/or electrolyte imbalance, debilitation, hypoxic episodes, and/or the use of other drugs (e.g., broad-spectrum antibiotics, narcotics, steroids) may prolong the effects of atracurium.

Monitor:

This drug produces apnea. Controlled artificial ventilation with oxygen must be continuous and under direct observation at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor response to atracurium and avoid overdose. ■ Patient may be conscious and completely unable to communicate by any means. Has no analgesic or sedative properties. ■ Action potentiated by hypokalemia and some carcinomas. ■ Action is altered by dehydration, electrolyte imbalance, body temperature, and acid-base imbalance. ***Mechanical ventilation support in ICU:*** Physical therapy is recommended to prevent muscular weakness, atrophy, and joint contracture. Muscular weakness may be first noticed during attempts to wean patient from the ventilator.

Maternal/Child:

Category C: use in pregnancy only if use justifies potential risk to fetus. Has been used during cesarean section; monitor infant carefully. ■ Use caution during breast-feeding. ■ Safety for use in infants under 1 month of age not established. ■ Contains benzyl alcohol; may cause “gasping syndrome” in premature infants.

Elderly:

No adjustments identified.

DRUG/LAB INTERACTIONS

Potentiated by **general anesthetics** (e.g., enflurane, isoflurane, halothane), **many antibiotics** (e.g., lincosamides [clindamycin (Cleocin)], aminoglycosides [kanamycin, gentamicin], polypeptides [bacitracin, colistimethate]), **corticosteroids, diuretics, diazepam** (Valium) **and other muscle relaxants, magnesium sulfate, meperidine, morphine, procainamide**, **quinidine, succinylcholine, verapamil, and others.** May need to reduce dose of atracurium; use with caution. ■ Duration of neuromuscular block may be shorter and dose requirements may be higher during maintenance infusion in patients stabilized on **carbamazepine** (Tegretol) **and phenytoin** (Dilantin). ■ Antagonized by **acetylcholine, anticholinesterases, azathioprine, and theophylline.** ■ **Succinylcholine** must show signs of wearing off before atracurium is given. Use caution.

SIDE EFFECTS

Prolonged action resulting in respiratory insufficiency or apnea. Airway closure caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions including anaphylaxis are possible. Bradycardia, bronchospasm, dyspnea, flushing, histamine release, hypotension, laryngospasm, reaction at injection site, shock, and tachycardia may occur. Rare reports of seizures with use of atracurium in ICU could be caused by other conditions or medications. Malignant hyperthermia is rare but may occur.

ANTIDOTE

All side effects are medical emergencies. Treat symptomatically. Controlled artificial ventilation must be continuous. Pyridostigmine (Regonol) or neostigmine given with atropine will probably reverse the muscle relaxation. Not effective in all situations; may aggravate severe overdosage. Resuscitate as necessary.

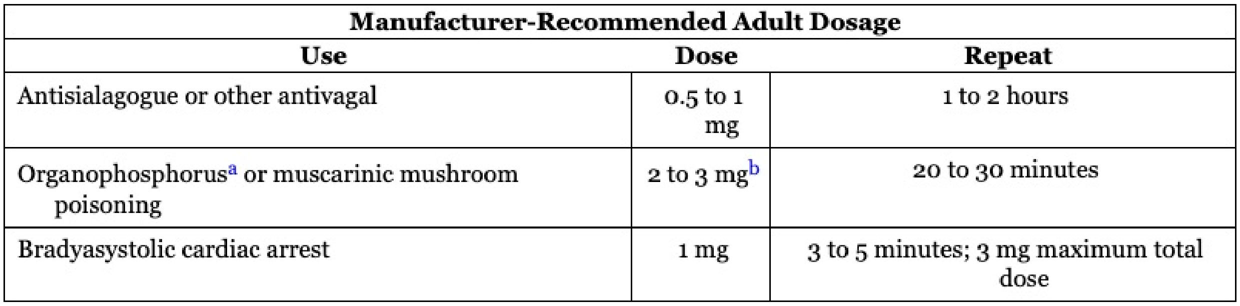
ATROPINE SULFATE

(**AH**-troh-peen **SUL**-fayt)
Atropine
Anticholinergic
Antiarrhythmic
Antidote
pH 3 to 6.5

USUAL DOSE

IV administration is usually preferred, but subcutaneous, intramuscular, and endotracheal administration are possible. For administration via an endotracheal tube, dilute 1 to 2 mg in no more than 10 mL of SW or NS.

Titrate dose based on HR, PR interval, BP, and symptoms. Manufacturer-recommended adult doses are outlined in the following chart.



Manufacturer-Recommended Adult Dosage

Use	Dose	Repeat
Antisialagogue or other antivagal	0.5 to 1 mg	1 to 2 hours
Organophosphorus[a] or muscarinic mushroom poisoning	2 to 3 mg[b]	20 to 30 minutes
Bradyasystolic cardiac arrest	1 mg	3 to 5 minutes; 3 mg maximum total dose

[a] Atropine is given in conjunction with pralidoxime for organophosphate insecticide and nerve agent poisoning.

[b] Higher doses have been used in severe poisoning. Consult a regional poison control center.

Other sources recommend the following doses:

Inhibition of salivation and secretions (preanesthesia):

0.4 to 0.6 mg 30 to 60 minutes preoperatively and repeat every 4 to 6 hours as needed.

Bradycardia:

0.5 mg every 3 to 5 minutes, not to exceed a total dose of 3 mg or 0.04 mg/kg.

Reversal of neuromuscular blockade:

15 to 30 mcg/kg administered with neostigmine or 7 to 10 mcg/kg administered with edrophonium. Administer in a separate syringe either concurrently or a few minutes before administering the anticholinesterase agent. If bradycardia is present, administer

atropine first.

Cardiac asystole or pulseless electrical activity:

AHA guidelines state, “Routine use during pulseless electrical activity or asystole is unlikely to have a therapeutic benefit.”

PEDIATRIC DOSE

Fatal dose of atropine in pediatric patients may be as low as 10 mg. See Maternal/Child.

Dosing in pediatric patients has not been well studied. The manufacturer lists a usual initial dose of 0.01 to 0.03 mg/kg. Doses less than 0.1 mg have been associated with a paradoxical bradycardia.

Other sources recommend the following doses:

Inhibition of salivation and secretions (preanesthesia):

Administer 30 to 60 minutes preoperatively and repeat every 4 to 6 hours as needed. ***Infants; weight less than 5 kg:*** 0.02 mg/kg/dose. There is no documented minimum dose for patients in this age/weight range. ***Infants and children; weight equal to or more than 5 kg:*** 0.01 to 0.02 mg/kg/dose; maximum single dose should not exceed 0.4 mg. Minimum recommended dose is 0.1 mg.

Bradycardia:

Infants; weight less than 5 kg: 0.02 mg/kg/dose. There is no documented minimum dose for patients in this age/weight range. ***Infants and children; weight equal to or more than 5 kg:*** 0.02 mg/kg/dose; maximum single dose should not exceed 0.5 mg. May repeat one time in 3 to 5 minutes; maximum total dose should not exceed 1 mg. Minimum recommended dose is 0.1 mg.

Antidote for acute poisoning from exposure to anticholinesterase compounds (e.g., organophosphate compounds, nerve gases, mushroom poisoning):

0.05 to 0.1 mg/kg; repeat every 5 to 10 minutes until muscarinic S/S subside. Administer repeat doses as needed based on recurrence of symptoms.

Reversal of neuromuscular blockade:

0.01 to 0.02 mg/kg of atropine concomitantly with 0.04 mg/kg of neostigmine. See Usual Dose for additional information.

DOSE ADJUSTMENTS

Reduced dose may be indicated in the elderly based on decreased organ function and/or concomitant disease or other drug therapy. ■ See Precautions, Drug/Lab Interactions, and Pediatric Dose.

DILUTION

May be given undiluted. Do not add to IV solutions. Inject through Y-tube or three-way stopcock of infusion set.

Storage:

Store at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer undiluted by rapid IV injection. Slow injection may cause a paradoxical bradycardia.

ACTIONS

Atropine is an anticholinergic drug and a potent belladonna alkaloid. An antimuscarinic agent that competitively antagonizes the muscarine-like actions of acetylcholine and other choline esters. Produces local, central, and peripheral effects on the body. Main therapeutic uses are peripheral, affecting smooth muscle, cardiac muscle, and exocrine gland cells. Increases heart rate and cardiac output and dries secretions. Widely distributed, metabolized by the liver via enzymatic hydrolysis, and excreted in urine. Half-life in adults is approximately 3 hours. Half-life in pediatric patients and adults over 65 years of age may be more than doubled. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Temporary blockade of severe or life-threatening muscarinic effects (e.g., as an antisialagogue, an antivagal agent, an antidote for organophosphorus or muscarinic mushroom poisoning, and for treatment of bradyasystolic cardiac arrest).

CONTRAINDICATIONS

Manufacturer states, “None.” Other sources list hypersensitivity to atropine. No contraindications exist in the treatment of life-threatening organophosphorus or carbamate insecticide or nerve agent poisoning.

PRECAUTIONS

Use with caution in patients with coronary artery disease. When recurrent use is essential, the total dose should be restricted to 2 to 3 mg (0.03 to 0.04 mg/kg) to avoid the detrimental effects of atropine-induced tachycardia on myocardial oxygen demand. ■ May precipitate acute glaucoma. ■ May convert partial organic pyloric stenosis into complete obstruction. ■ May cause complete urinary retention in patients with prostatic hypertrophy. ■ May cause thickening of bronchial secretions and the formation of viscid mucous plugs in patients with chronic lung disease. ■ Use with caution in patients with cardiovascular disease, pulmonary disease, autonomic neuropathy, GI disease (e.g., paralytic ileus, intestinal atony, severe ulcerative colitis, toxic megacolon), hyperthyroidism, myasthenia gravis, and renal or hepatic impairment.

Monitor:

Vital signs and/or ECG based on specific situation. ■ Monitor for resolution or return of symptoms in episodes of poisoning. ■ Monitor for S/S of atropine toxicity (e.g., blurred vision, delirium, fever, muscle fasciculations, hot, dry skin).

Patient Education:

Use caution if task requires alertness; may cause blurred vision, dizziness, or drowsiness. ■ Report eye pain, flushing, or skin rash promptly. ■ Report dry mouth, difficulty urinating, constipation, or increased light sensitivity.

Maternal/Child:

Category C: safety for use in pregnancy, breast-feeding, and pediatric patients not established. ■ Pediatric patients may be more sensitive to anticholinergic effects.

Elderly:

May be more sensitive to adverse effects. ■ Potential for constipation and urinary retention increased. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

May have additive effects when used in combination with **other agents with anticholinergic properties** (e.g., glycopyrrolate, phenothiazines, tricyclic antidepressants). ■ May potentiate effects of many oral drugs by delaying gastric emptying and increasing absorption (e.g., **atenolol, digoxin, nitrofurantoin, thiazide diuretics**). ■ Decreases the rate of **mexiletine** absorption without altering the relative oral bioavailability. ■ Antagonizes **anticholinesterase inhibitors** (e.g., edrophonium, pyridostigmine).

SIDE EFFECTS

Most side effects of atropine are directly related to its antimuscarinic action. Blurred vision, dryness of the mouth, photophobia, and tachycardia commonly occur. Other possible reactions include anhidrosis (leading to heat intolerance), constipation, dilation of the pupils, flushing, heat prostration from decreased sweating, hypersensitivity reactions (e.g., skin rashes that in some cases progressed to exfoliation), nausea, paralytic ileus, tachycardia, urinary hesitancy and retention (especially in males), and vomiting.

Overdose:

Excessive doses may cause ataxia; difficulty swallowing; dilated pupils; dizziness; fatigue; hot, dry skin; palpitations; restlessness; thirst; and tremor. ***Toxic doses*** may lead to restlessness and excitation, hallucinations, delirium, and coma. ***Severe intoxication*** may lead to depression and circulatory collapse, paralysis, coma, respiratory failure, and death.

ANTIDOTE

Discontinue if side effects increase or are severe. Notify physician. Use standard treatments to manage cardiac arrhythmias. Physostigmine salicylate (1 to 4 mg [0.5 to 1 mg in pediatric patients]) reverses most cardiovascular and CNS effects. Repeat doses as needed. Diazepam or a short-acting barbiturate may be administered as needed to control marked excitement and convulsions. Large doses should be avoided because central depressant action may coincide with the depression that occurs late in atropine poisoning. Central stimulants are not recommended. Artificial respiration with oxygen may be necessary. Ice bags and alcohol sponges help to reduce fever, especially in pediatric patients. Atropine is not removed by dialysis.

AVALGLUCOSIDASE ALFA

(ay-val-gloo-**KOE**-si-dase AL-fa)
Nexviazyme
Enzyme

USUAL DOSE

Adult:

Actual body weight (ABW) less than 30 kg:

40 mg/kg IV every 2 weeks.

ABW 30 kg or more:

20 mg/kg IV every 2 weeks.

PEDIATRIC DOSE

ABW less than 30 kg:

40 mg/kg IV every 2 weeks.

ABW 30 kg or more:

20 mg/kg IV every 2 weeks.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

Hypersensitivity reactions:

Decrease rate or stop if hypersensitivity reaction occurs. If symptoms persist after stopping, wait 30 minutes for symptoms to resolve. If symptoms subside, resume infusion at one-half of the infusion rate at which reaction occurred for 30 minutes, then increase rate by 50% for 15 to 30 minutes. If symptoms do not recur, increase to the infusion rate at which reaction occurred and continue to increase rate in stepwise manner. Severe hypersensitivity or anaphylaxis reactions require stopping infusion immediately and beginning appropriate medical management.

Infusion-related reaction:

Mild or moderate reaction:

Temporarily hold infusion or decrease infusion and begin appropriate medical management. If symptoms resolve after 30 minutes, resume infusion at 50% of rate at which reaction occurred, then increase rate by 50% for 15 to 30 minutes. If symptoms do not recur, infusion rate can be increased to the rate at which symptoms occurred.

DILUTION

Before reconstitution, allow vials to reach room temperature. Reconstitute each vial with 10 mL of SWFI. Inject the SWFI down internal wall of vial. Gently roll and tilt; ***do not shake or invert***. Depending on weight, add the appropriate dose to between 200 and 700 mL of D5W. Refer to package insert.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than D5W.

RATE OF ADMINISTRATION

Use a separate line with an in-line, low–protein binding, 0.2-micron filter. Diluted solution must be used within 9 hours.

For ABW less than 30 kg:

Initial infusion:

Start at 1 mg/kg/hr. If tolerated, gradually increase rate every 30 minutes to 3 mg/kg/hr, then 5 mg/kg/hr, then 7 mg/kg/hr. Total infusion time is about 7 hours. Flush line with D5W after infusion.

Subsequent infusions:

Start at 1 mg/kg/hr. If tolerated, increase as listed for initial infusion. Alternately, may increase rate every 30 minutes as follows: 3 mg/kg/hr, then 6 mg/kg/hr, then 8 mg/kg/hr, then 10 mg/kg/hr. Total infusion time is about 5 hours. Flush line with D5W after infusion.

For ABW greater than 30 kg:

Initial infusion:

Start at 1 mg/kg/hr. If tolerated, gradually increase rate every 30 minutes to 3 mg/kg/hr, then 5 mg/kg/hr, then 7 mg/kg/hr. Total infusion time is about 4 to 5 hours. Flush line with D5W after infusion.

ACTIONS

Avalglucosidase alfa is an exogenous source of the enzyme acid alpha-glucosidase.

INDICATIONS AND USES

Pompe disease.

CONTRAINDICATIONS

No contraindications listed by manufacturer.

PRECAUTIONS

Hypersensitivity and infusion-related reactions (see Dose Adjustments).

Monitor:

Monitor vital signs during and prior to each rate increase and following the infusion. Monitor for hypersensitivity and infusion-related reactions.

Patient Education:

Contact doctor if symptoms of headache, diarrhea, emesis, stomach pain, dizziness, fatigue, weakness, or muscle or joint pain do not go away. Avalglucosidase alfa may cause infusion-related reactions. Contact physician for any signs of infusion-related reactions (e.g., high or low blood pressure; shortness of breath; fever or chills; burning, numbness, or tingling feeling that is not normal). Also contact physician or get medical help for any signs of allergic reactions (e.g., hives; rash; red, swollen, blistered, or peeling skin; tightness in chest or throat; trouble breathing, swallowing, or talking; unusual hoarseness; swelling of mouth, face, lips, tongue, or throat).

Maternal/Child:

Unknown. Refer to physician before infusion if patient may be or is pregnant.

Elderly:

Refer to adult dosing and precautions.

DRUG/LAB INTERACTIONS

No known significant drug interactions.

SIDE EFFECTS

Diarrhea, nausea, hypersensitivity reaction, antibody development, fatigue, headache, hypotension, hypertension, erythema of skin, abdominal pain, arthralgia, myalgia, cough, dyspnea, fever.

ANTIDOTE

Discontinue infusion and treat appropriately if signs of severe hypersensitivity reaction occur.

AVELUMAB

(a-**VEL**-ue-mab)
Bavencio
Antineoplastic agent
Monoclonal antibody (Anti-PD-L1)
pH 5 to 5.6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Premedication:

Premedicate with an antihistamine (e.g., diphenhydramine) and acetaminophen before the first 4 infusions of avelumab. Administer for subsequent avelumab doses based on clinical judgment and the presence/severity of prior infusion reactions. See Monitor.

Metastatic Merkel cell carcinoma and urothelial carcinoma:

800 mg as an IV infusion over 60 minutes every 2 weeks until disease progression or unacceptable toxicity.

Renal cell carcinoma:

800 mg as an IV infusion over 60 minutes every 2 weeks in combination with axitinib 5 mg orally taken twice daily (12 hours apart) with or without food until disease progression or unacceptable toxicity. When axitinib is used in combination with avelumab, dose escalation of axitinib above the initial 5-mg dose may be considered at intervals of 2 weeks or longer. Review the full prescribing information for axitinib before initiation.

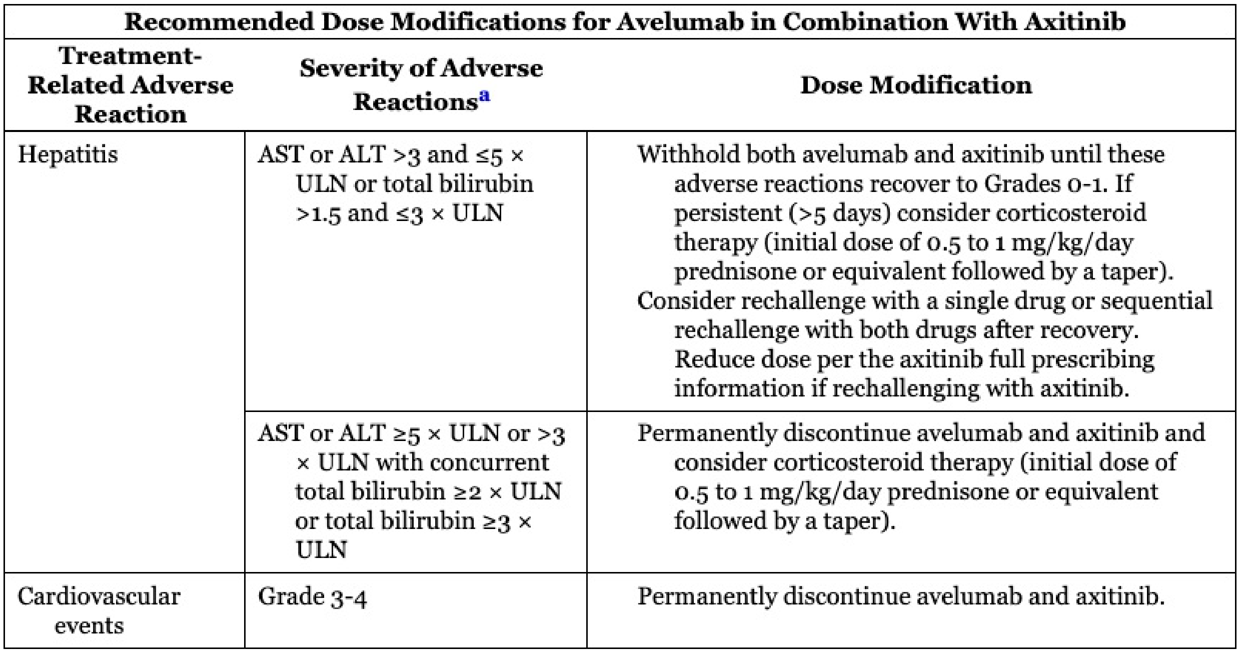
DOSE ADJUSTMENTS

Recommended Dose Modifications for Avelumab		
Treatment-Related Adverse Reaction	**Severity of Adverse Reactions[a]**	**Dose Modification**
Pneumonitis	Grade 2 pneumonitis	Withhold avelumab. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of pneumonitis after corticosteroid taper.
	Grade 3 or 4 pneumonitis or recurrent Grade 2 pneumonitis	Permanently discontinue avelumab.
Hepatitis	AST or ALT more than 3 and up to 5 × ULN or total bilirubin more than 1.5 and up to 3 × ULN	Withhold avelumab. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of hepatitis after corticosteroid taper.
For avelumab in combination with axitinib, see the following chart.	AST or ALT more than 5 × ULN or total bilirubin more than 3 × ULN	Permanently discontinue avelumab.
Colitis	Grade 2 or 3 diarrhea or colitis	Withhold avelumab. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of colitis or diarrhea after corticosteroid taper.
	Grade 4 diarrhea or colitis or recurrent Grade 3 diarrhea or colitis	Permanently discontinue avelumab.

Endocrinopathies (including but not limited to hypothyroidism, hyperthyroidism, adrenal insufficiency, hyperglycemia)	Grade 3 or 4 endocrinopathies	Withhold avelumab. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of endocrinopathies after corticosteroid taper.
Nephritis and renal dysfunction	Serum creatinine more than 1.5 and up to 6 × ULN	Withhold avelumab. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of nephritis and renal dysfunction after corticosteroid taper.
	Serum creatinine more than 6 × ULN	Permanently discontinue avelumab.
Other immune-mediated adverse reactions, including but not limited to anemia, arthritis, bullous dermatitis, demyelination, encephalitis, erythema multiforme, exfoliative dermatitis, Guillain-Barré syndrome, hemolytic anemia, histiocytic necrotizing lymphadenitis, hypophysitis, hypopituitarism, iritis, myasthenia gravis, myocarditis, myositis, pancreatitis, pemphigoid, psoriasis, rhabdomyolysis, Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN), uveitis, and vasculitis[b]	For any of the following: • Moderate or severe clinical signs or symptoms of an immune-mediated adverse reaction not described above • Grade 3 or 4 endocrinopathies	Withhold avelumab pending clinical evaluation. Resume avelumab in patients with complete or partial resolution (Grade 0 to 1) of other immune-mediated adverse reactions after corticosteroid taper.
	For any of the following: • Life-threatening adverse reaction (excluding endocrinopathies) • Recurrent severe immune-mediated adverse reaction • Requirement for 10 mg/day or greater prednisone or equivalent for more than 12 weeks • Persistent Grade 2 or 3 immune-mediated adverse reactions lasting 12 weeks or longer	Permanently discontinue avelumab.
Infusion-related reaction	Grade 1 or 2	Interrupt or slow the rate of infusion.
	Grade 3 or 4	Permanently discontinue avelumab.

[a] Toxicity was graded per National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), Version 4.

[b] Observed with avelumab or with other anti-PD-1/PD-L1 monoclonal antibodies.



Recommended Dose Modifications for Avelumab in Combination With Axitinib		
Treatment-Related Adverse Reaction	**Severity of Adverse Reactions[a]**	**Dose Modification**
Hepatitis	AST or ALT >3 and ≤5 × ULN or total bilirubin >1.5 and ≤3 × ULN	Withhold both avelumab and axitinib until these adverse reactions recover to Grades 0-1. If persistent (>5 days) consider corticosteroid therapy (initial dose of 0.5 to 1 mg/kg/day prednisone or equivalent followed by a taper). Consider rechallenge with a single drug or sequential rechallenge with both drugs after recovery. Reduce dose per the axitinib full prescribing information if rechallenging with axitinib.
	AST or ALT ≥5 × ULN or >3 × ULN with concurrent total bilirubin ≥2 × ULN or total bilirubin ≥3 × ULN	Permanently discontinue avelumab and axitinib and consider corticosteroid therapy (initial dose of 0.5 to 1 mg/kg/day prednisone or equivalent followed by a taper).
Cardiovascular events	Grade 3-4	Permanently discontinue avelumab and axitinib.

[a]Toxicity was graded per National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE), Version 4.

No pharmacokinetic differences were observed in patient subgroups defined by age, gender, race, PD-L1 status, tumor burden, and hepatic and renal function (mild, moderate, or severe renal insufficiency; mild to moderate impaired hepatic function). The pharmacokinetics of avelumab is unknown in patients with severe hepatic impairment. ■ In patients with advanced RCC, avelumab clearance in patients who tested positive for treatment-emergent antidrug antibodies (ADA) was 15% higher as compared with clearance in patients who tested negative. ■ See Monitor and Precautions.

DILUTION

Available as a 200 mg/10 mL (20 mg/mL) clear, colorless to slightly yellow solution in a single-dose vial. Withdraw the required volume of avelumab from the vial(s) and inject it into a 250-mL infusion bag containing either NS or $^{1}/_{2}$NS. Gently invert the bag to mix the diluted solution, and avoid foaming or excessive shearing. ***Do not shake***. Inspect the solution to ensure it is clear, colorless, and free of visible particles.

Filters:

Use of sterile, nonpyrogenic, low–protein-binding in-line filter (pore size of 0.2 micron) required.

Storage:

Before use, refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake. Store diluted avelumab at RT up to 25° C (77° F) for no more than 4 hours from the time of dilution **OR** under refrigeration at 2° to 8° C (36° to 46° F) for no more than 24 hours from the time of dilution. Do not freeze. If refrigerated, allow the diluted solution to come to RT before administration. Protect diluted solution from light. Discard any partially used or empty vials.

COMPATIBILITY

Manufacturer states, “Do not coadminister other drugs through the same intravenous line.”

RATE OF ADMINISTRATION

A single dose equally distributed over 60 minutes through an IV line containing a sterile, nonpyrogenic, low–protein-binding in-line filter (pore size of 0.2 micron). Interrupt or slow the rate of infusion for mild or moderate infusion-related reactions; see Dose Adjustments.

ACTIONS

A human IgG1 lambda monoclonal antibody. Avelumab is a programmed death ligand-1 (PD-L1) blocking antibody. Avelumab binds PD-L1 and blocks the interaction between PD-L1 and its receptors PD-1 and B7.1. This interaction releases the inhibitory effects of PD-L1 on the immune response, resulting in the restoration of immune responses, including antitumor immune responses. Shown to induce antibody-dependent cell-mediated cytotoxicity (ADCC) in vitro. Primary elimination mechanism is proteolytic degradation. Terminal half-life was 6.1 days in patients receiving 10 mg/kg. When avelumab 10 mg/kg was administered in combination with axitinib 5 mg, the respective exposures of avelumab and axitinib were comparable to the single agents.

INDICATIONS AND USES

Treatment of adults and pediatric patients 12 years and older with metastatic Merkel cell carcinoma (MCC). ■ Treatment of patients with locally advanced or metastatic urothelial carcinoma (UC) who have disease progression during or following platinum-containing chemotherapy or who have disease progression within 12 months of neoadjuvant or adjuvant treatment with platinum-containing therapy. These indications are approved under accelerated approval based on tumor response and duration of response. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trials. ■ Treatment of patients with advanced renal cell carcinoma (RCC) in combination with axitinib.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Avelumab can cause immune-mediated pneumonitis, including fatal cases. ■ Avelumab can cause immune-mediated hepatitis, including fatal cases. ■ Avelumab can cause immune-mediated colitis. ■ Avelumab can cause immune-mediated endocrinopathies (e.g., adrenal insufficiency, thyroid disorders [hypothyroidism/hyperthyroidism], Type 1 diabetes mellitus, including diabetic ketoacidosis). ■ Avelumab can cause immune-mediated thyroid disorders. Thyroid disorders can occur at any time during treatment. Manage hypothyroidism with hormone-replacement therapy. Initiate medical management for control of hyperthyroidism. ■ Avelumab can cause type 1 diabetes mellitus, including diabetic ketoacidosis. Withhold avelumab and administer antihyperglycemics or insulin in patients with severe or life-threatening hyperglycemia. ■ Avelumab can cause immune-mediated nephritis. ■ Avelumab can result in other severe and fatal immune-mediated adverse reactions; see Dose Adjustments. These immune-mediated reactions may involve any organ system. Most immune-mediated reactions initially manifest during avelumab treatment but may occur after discontinuation. ■ Avelumab can cause severe or life-threatening infusion-related reactions. These reactions may occur after completion of the infusion. Premedicate with an antihistamine and acetaminophen before the first 4 infusions; see Usual Dose. ■ Avelumab in combination with axitinib can cause severe and fatal cardiovascular events. Optimize management of cardiovascular risk factors such as diabetes, dyslipidemia, or hypertension. ■ A protein substance; has a potential for immunogenicity.

Monitor:

Obtain baseline serum creatinine, serum glucose, liver function tests, and thyroid function tests before initiating treatment, and monitor periodically during treatment and as indicated based on clinical evaluation. ■ When using avelumab in combination with axitinib, consider baseline and periodic evaluations of left ventricular ejection fraction and more frequent monitoring of liver enzymes. ■ Monitor for S/S of pneumonitis, and evaluate patients with suspected pneumonitis with radiographic imaging. ■ Monitor for S/S of colitis. ■ Monitor for S/S of adrenal insufficiency during and after treatment. Administer corticosteroids as appropriate for adrenal insufficiency. ■ Monitor for hyperglycemia or other S/S of diabetes. For patients with severe or life-threatening hyperglycemia, resume treatment with avelumab when metabolic control is achieved with insulin replacement or antihyperglycemics. ■ Monitor for other possible immune-mediated adverse reactions. Evaluate to confirm or rule out an immune-mediated adverse reaction and to exclude other causes. Use of high-dose corticosteroids and/or hormone replacement therapy may be indicated. ■ Monitor for S/S of infusion-related reactions, including abdominal pain, back pain, chills, dyspnea, fever, flushing, hypotension, urticaria, and wheezing. ■ Administer corticosteroids (initial dose of 1 to 2 mg/kg/day prednisone or equivalent, followed by a corticosteroid taper) for Grade 2 or greater colitis, hepatitis, nephritis, pneumonitis, or other immune-mediated reactions. ■ Monitor for S/S of cardiovascular events. ■ See Precautions and Dose Adjustments.

Patient Education:

Review manufacturer's medication guide. ■ Review medical conditions and medications with health care provider. ■ Avoid pregnancy; females of childbearing potential should use effective contraception during treatment with avelumab and for at least 1 month after the last dose. ■ Promptly report S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of abdomen, or severe nausea or vomiting). ■ Promptly report S/S of colitis (e.g., diarrhea or severe abdominal pain). ■ Promptly report S/S of endocrinopathies (e.g., adrenal insufficiency, diabetes mellitus, hyperthyroidism, or hypothyroidism). ■ Promptly report S/S of nephritis and renal dysfunction (e.g., blood in urine, decreased urine output, loss of appetite, swelling in ankles, or any other symptoms of renal dysfunction). ■ Promptly report S/S of infusion-related reactions (e.g., chills, fever, hives, and shortness of breath or wheezing). ■ Promptly report S/S of cardiovascular events (e.g., dyspnea, new or worsening chest discomfort, or peripheral edema).

Maternal/Child:

Based on its mechanism of action, avelumab can cause fetal harm. Females of reproductive potential should use effective contraception during treatment with avelumab and for at least 1 month after the last dose. ■ Discontinue breast-feeding during therapy with avelumab and for at least 1 month after final dose. ■ Safety and effectiveness for use in pediatric patients under 12 years of age not established.

Elderly:

Studies with MCC did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently than younger patients. No overall differences in safety or efficacy were reported between elderly patients and younger patients in UC or RCC studies.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted.

SIDE EFFECTS

The most common side effects reported were abdominal pain, cough, decreased appetite, diarrhea, dysphonia, dyspnea, fatigue, headache, hepatoxicity, hypertension, hypothyroidism, infusion-related reactions, mucositis, musculoskeletal pain, nausea, palmar-plantar erythrodysesthesia, peripheral edema, rash, and urinary tract infections. Other side effects reported were arthralgia, constipation, decreased weight, dizziness, fever, pruritus, and vomiting. Laboratory abnormalities included anemia; decreased hemoglobin and platelet count; hyperglycemia; hyperkalemia; hyponatremia; increased alkaline phosphatase, ALT, amylase, AST, bilirubin, cholesterol, creatinine, GGT, lipase, and triglycerides; lymphopenia; neutropenia; and thrombocytopenia. Serious immune-mediated colitis, immune-mediated endocrinopathies, immune-mediated hepatitis (as a single agent and in combination with axitinib) and hepatoxicity, immune-mediated nephritis and renal dysfunction, immune-mediated pneumonitis, and other immune-mediated reactions have occurred. Major adverse cardiovascular events have also occurred. For complete list of adverse reactions, see full prescribing information.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Withhold or permanently discontinue avelumab as outlined in the chart in Dose Adjustments. Discontinue avelumab and axitinib for Grade 3 or 4 cardiovascular events. For life-threatening infusion reactions, immediately and permanently stop avelumab and administer appropriate supportive treatment. For less severe infusion reactions, management may involve temporarily stopping the infusion, reducing the infusion rate, and/or administering symptomatic treatment (e.g., IV saline, diphenhydramine, bronchodilators such as albuterol and acetaminophen). Resuscitate if indicated.

AXICABTAGENE CILOLEUCEL SUSPENSION BBW

(ax-i-**CAB**-tay-jeen sye-**LO**-loo-sel)
Yescarta
Chimeric antigen receptor T-cell (CAR-T)
Immunotherapy
Antineoplastic agent

USUAL DOSE

For autologous use only. For IV use only.

Pretreatment:

Verify pregnancy status. Screen patients for HBV, HCV, and HIV before leukapheresis procedure. See Precautions and Drug/Lab Interactions. ***Confirm the availability*** of axicabtagene ciloleucel before starting the lymphodepleting chemotherapy regimen.

Lymphodepleting chemotherapy regimen:

On the fifth, fourth, and third day ***before*** infusion of axicabtagene ciloleucel, administer cyclophosphamide 500 mg/M^2 IV and fludarabine 30 mg/M^2 IV. See cyclophosphamide and fludarabine monographs.

Premedication:

Approximately 1 hour before the infusion of axicabtagene ciloleucel, administer acetaminophen 650 mg PO and diphenhydramine 12.5 mg IV or PO. Avoid prophylactic use of systemic corticosteroids because this may interfere with the activity of axicabtagene ciloleucel.

Axicabtagene ciloleucel:

Patient’s identity must match the patient identifiers on the axicabtagene ciloleucel cassette and infusion bag. Do not infuse if the information on the patient-specific label does not match the intended patient. Each single infusion bag of axicabtagene ciloleucel contains a suspension of chimeric antigen receptor (CAR)-positive T-cells in approximately 68 mL. The target dose is 2×10^6 CAR-positive viable T-cells/kg of body weight, with a maximum of 2×10^8 CAR-positive viable T-cells. Central venous access is recommended. See Precautions.

DOSE ADJUSTMENTS

No recommendations for Dose Adjustments indicated.

DILUTION

Special handling required: see Precautions. Confirm infusion time in advance and adjust the start time of the axicabtagene ciloleucel thaw so it will be available for infusion when the patient is ready. Each single infusion bag of axicabtagene ciloleucel contains a suspension of chimeric antigen receptor (CAR)-positive T-cells in approximately 68 mL. Confirm patient identity with patient identifiers on cassette, then remove the product bag from the cassette and confirm that the patient information on the cassette label matches the product bag label. Inspect product bag for breaks or cracks before thawing. If product bag is intact, place it inside a second sterile bag per local guidelines. Thaw axicabtagene ciloleucel at approximately 37° C (98.6° F) using either a water bath or dry thaw method until no ice is visible. Gently manually mix contents until all clumps of cellular material are dispersed. Do not wash, spin down, and/or resuspend in new media before infusion. Prime tubing with NS.

Filters:

Do not use a leukodepleting filter.

Storage:

Each infusion bag is individually packed for a specific patient in a metal cassette and stored in the vapor phase of liquid nitrogen and supplied in a liquid nitrogen dry shipper. Store frozen in the vapor phase of liquid nitrogen (at −150° C or less [−238° F or less]). Thaw before use. Once thawed, axicabtagene ciloleucel may be stored at RT (20° to 25° C [60° to 77° F]) for up to 3 hours.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Central venous access recommended. *Do not use* a leukodepleting filter. Prime tubing with NS. Infuse the entire contents of the product bag within 30 minutes either by gravity or a peristaltic pump. Gently agitate the product during the infusion to prevent cell clumping. After completion, rinse the tubing with NS at the same infusion rate to ensure all product is delivered.

ACTIONS

A CD19-directed, genetically modified, autologous T-cell immunotherapy. To prepare axicabtagene ciloleucel, a patient’s own T-cells are harvested through a standard leukapheresis procedure and genetically modified. The patient’s T-cells are reprogrammed with a transgene encoding a chimeric antigen receptor (CAR) to identify and eliminate CD19-expressing malignant and normal cells. The CAR is made up of a murine single-chain antibody fragment that recognizes CD19 and is fused to CD28 and CD3 zeta. When axicabtagene ciloleucel is then administered to the specific patient, it binds to his or her CD19-expressing cancer cells and normal B-cells. The CD28 and CD3 zeta co-stimulatory domains activate downstream signaling cascades that lead to T-cell activation, T-cell proliferation, acquisition of effector functions, and secretion of inflammatory cytokines and chemokines. This sequence of events leads to killing of CD19-expressing cells. Because of the on-target effect of axicabtagene ciloleucel, a period of B-cell aplasia is expected. Following the infusion of axicabtagene ciloleucel, anti-CD19 CAR T-cells exhibit an initial rapid expansion followed by a decline to near baseline levels by 3 months. Peak levels of anti-CD19 CAR T-cells occur within the first 7 to 14 days after the infusion. The number of anti-CD19 CAR T-cells in blood was positively associated with partial or complete remission.

INDICATIONS AND USES

A CD19-directed, genetically modified, autologous T-cell immunotherapy indicated for the treatment of adults with relapsed or refractory large B-cell lymphoma after two or more lines of systemic therapy, including diffuse large B-cell lymphoma (DLBCL) not otherwise specified, primary mediastinal large B-cell lymphoma, high-grade B-cell lymphoma, and DLBCL arising from follicular lymphoma.

Limitation of Use:

Not indicated for the treatment of patients with primary central nervous system lymphoma.

CONTRAINDICATIONS

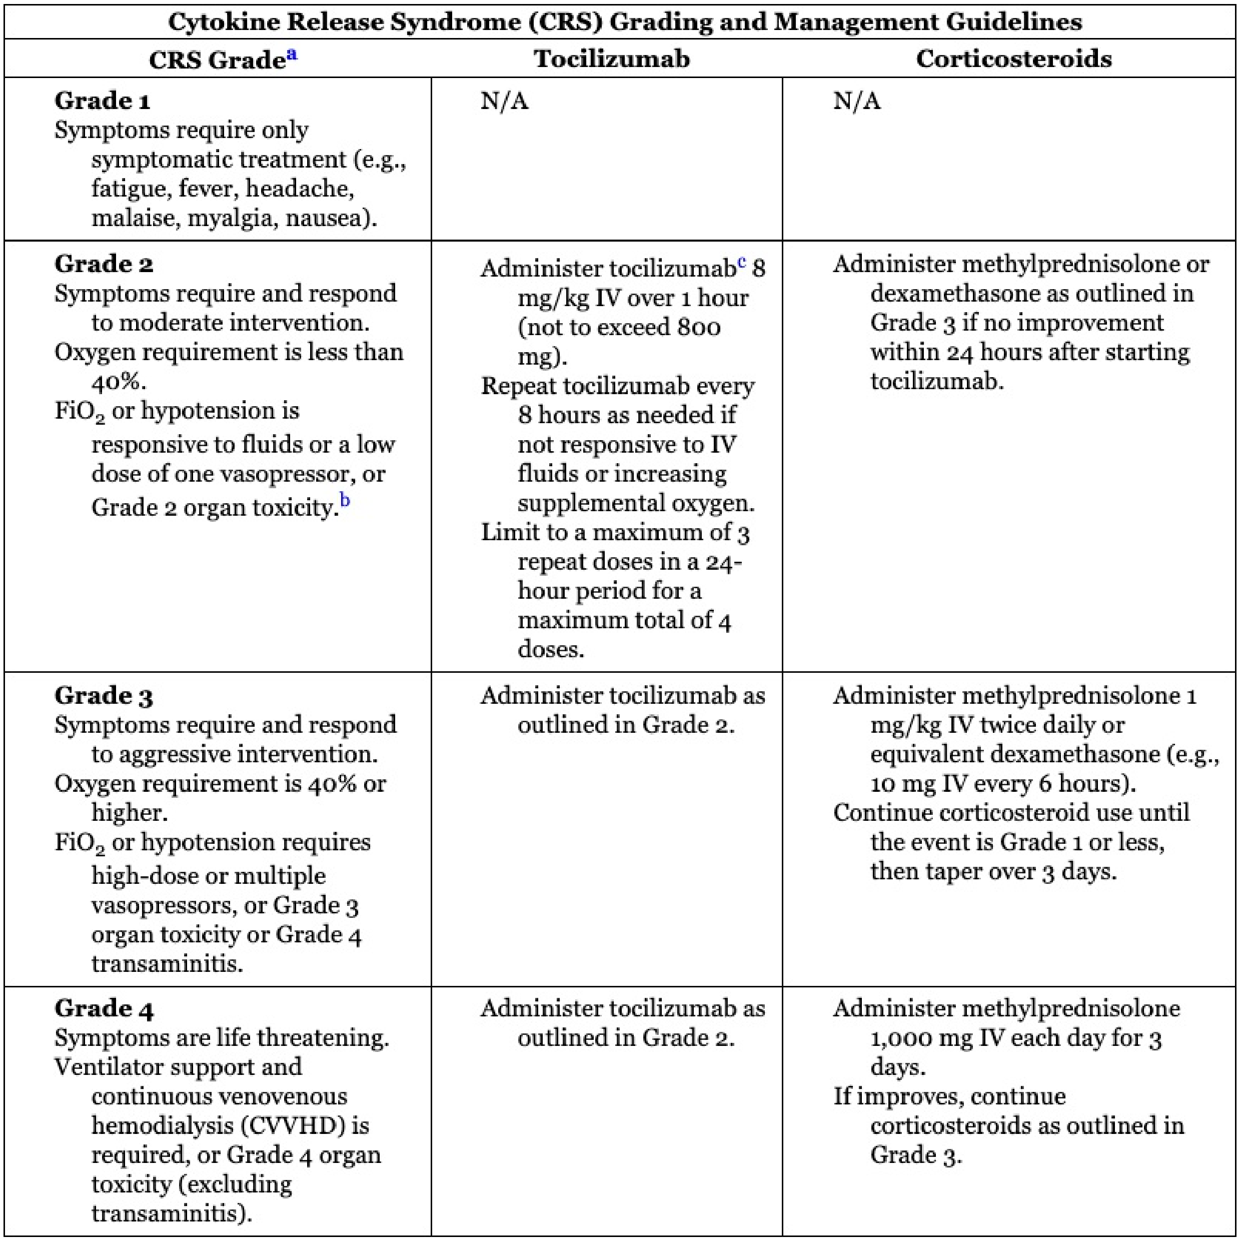
Manufacturer states, “None.”

PRECAUTIONS

For autologous use only. ■ **For IV use only.** ■ Contains human blood cells capable of transmitting infectious disease; follow local biosafety guidelines for handling and disposal. ■ Administer under the direction of a physician knowledgeable in its use in a certified health care facility with the ability to monitor the patient and respond to any medical emergency. Tocilizumab (Actemra) (at least 2 doses) and emergency drugs and equipment must be available before the infusion and during the recovery period. ■ Cytokine release syndrome (CRS), including fatal or life-threatening reactions, has occurred in patients receiving axicabtagene ciloleucel. Do not administer to patients with active infection or inflammatory disorders. Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids; see Monitor. ■ Fatal or life threatening neurologic toxicities have occurred in patients receiving axicabtagene ciloleucel, including concurrently with CRS or after CRS resolution. ■ Available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS) called the YESCARTA REMS; see prescribing information. ■ Serious hypersensitivity reactions, including anaphylaxis, may occur and may be a result of dimethyl sulfoxide (DMSO) or residual gentamicin. ■ Severe or life-threatening infections have occurred, including bacterial and viral infections and infections caused by unspecified pathogens. ■ Hepatitis B virus (HBV) reactivation can occur and in some cases result in fulminant hepatitis, hepatic failure, and death. ■ Prolonged cytopenias, including anemia, neutropenia, and thrombocytopenia, have been reported. Febrile neutropenia has occurred and may be concurrent with CRS. ■ B-cell aplasia and hypogammaglobulinemia can occur. ■ Secondary malignancies may develop; see prescribing information to obtain instructions on patient samples to collect for testing. ■ Has the potential to induce immunogenicity (antiproduct antibodies).

Monitor:

Patients must remain at the certified health care facility and be monitored daily for cytokine release syndrome (CRS) and neurologic toxicities for at least 7 days. Patients are to remain within proximity of the certified health care facility for at least 4 weeks following infusion. ■ Screen patients for HBV, HCV, and HIV before the leukapheresis procedure. ■ Monitor for S/S of infection before and after infusion and treat appropriately. Prophylactic antibiotics may be indicated. ■ Monitor CBC and platelets after the axicabtagene ciloleucel infusion. ■ Manage febrile neutropenia with broad-spectrum antibiotics, fluids, and supportive care as medically indicated. ■ Monitor for S/S of CRS (e.g., chills, fever, hypotension, hypoxia, tachycardia). Median time to onset was 2 days (range 1 to 12 days), and median duration was 7 days. Serious events that may be associated with CRS include capillary leak syndrome, cardiac arrest, cardiac arrhythmias (including atrial fibrillation and ventricular tachycardia), cardiac failure, hypotension, hypoxia, renal insufficiency, and hemophagocytic lymphohistiocytosis/macrophage activation syndrome (HLH/MAS). Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids. Patients who experience Grade 2 or higher CRS (e.g., hypotension, no response to fluids, or hypoxia requiring supplemental oxygenation) should be monitored with continuous cardiac telemetry and pulse oximetry. Consider an echocardiogram to assess cardiac function in patients experiencing severe CRS and intensive care supportive therapy for severe or life-threatening CRS. Grading and management guidelines for CRS are presented in the following chart.



Cytokine Release Syndrome (CRS) Grading and Management Guidelines

CRS Grade[a]	Tocilizumab	Corticosteroids
Grade 1 Symptoms require only symptomatic treatment (e.g., fatigue, fever, headache, malaise, myalgia, nausea).	N/A	N/A
Grade 2 Symptoms require and respond to moderate intervention. Oxygen requirement is less than 40%. FiO_2 or hypotension is responsive to fluids or a low dose of one vasopressor, or Grade 2 organ toxicity.[b]	Administer tocilizumab[c] 8 mg/kg IV over 1 hour (not to exceed 800 mg). Repeat tocilizumab every 8 hours as needed if not responsive to IV fluids or increasing supplemental oxygen. Limit to a maximum of 3 repeat doses in a 24-hour period for a maximum total of 4 doses.	Administer methylprednisolone or dexamethasone as outlined in Grade 3 if no improvement within 24 hours after starting tocilizumab.
Grade 3 Symptoms require and respond to aggressive intervention. Oxygen requirement is 40% or higher. FiO_2 or hypotension requires high-dose or multiple vasopressors, or Grade 3 organ toxicity or Grade 4 transaminitis.	Administer tocilizumab as outlined in Grade 2.	Administer methylprednisolone 1 mg/kg IV twice daily or equivalent dexamethasone (e.g., 10 mg IV every 6 hours). Continue corticosteroid use until the event is Grade 1 or less, then taper over 3 days.
Grade 4 Symptoms are life threatening. Ventilator support and continuous venovenous hemodialysis (CVVHD) is required, or Grade 4 organ toxicity (excluding transaminitis).	Administer tocilizumab as outlined in Grade 2.	Administer methylprednisolone 1,000 mg IV each day for 3 days. If improves, continue corticosteroids as outlined in Grade 3.

[a] Lee DW et al; Current concepts in the diagnosis and management of cytokine release syndrome. *Blood* 124(2):188–195, 2014.

[b] Refer to the next chart for management of neurologic toxicity.

[c] Refer to tocilizumab prescribing information for details.

- Monitor immunoglobulin levels after the axicabtagene ciloleucel infusion. Manage using infection precautions, antibiotic prophylaxis, and immunoglobulin replacement.
- Monitor for S/S of neurologic toxicities (e.g., anxiety, aphasia, delirium, dizziness, encephalopathy, headache, insomnia, tremor). Serious events include cerebral edema, leukoencephalopathy, and seizures. Most occur within the first 8 weeks after the initial infusion (with a median time to onset of 4 days [range 1 to 43 days]). The median duration of neurologic toxicities was 17 days. Rule out other causes of neurologic

symptoms. Provide supportive care and/or corticosteroids as needed. Neurologic toxicity grading and management guidelines are presented in the following chart.

Neurologic Toxicity Grading and Management Guidelines

- Patients with Grade 2 or higher neurologic toxicities should be monitored with continuous cardiac telemetry and pulse oximetry.
- Provide intensive care supportive therapy for severe or life-threatening neurologic toxicities.
- Consider nonsedating antiseizure medicines (e.g., levetiracetam) for seizure prophylaxis for any Grade 2 or higher neurologic toxicities.

Grading Assessment	**Concurrent Cytokine Release Syndrome**	**No Concurrent Cytokine Release Syndrome**
Grade 2	Administer tocilizumab as outlined in previous chart for management of Grade 2 CRS. If no improvement within 24 hours after starting tocilizumab, administer dexamethasone 10 mg IV every 6 hours if not already taking other corticosteroids. Continue dexamethasone use until the event is Grade 1 or less, then taper over 3 days.	Administer dexamethasone 10 mg IV every 6 hours. Continue dexamethasone use until the event is Grade 1 or less, then taper over 3 days.
Grade 3	Administer tocilizumab as outlined in previous chart for management of Grade 2 CRS. In addition, administer dexamethasone 10 mg IV with the first dose of tocilizumab and repeat every 6 hours. Continue dexamethasone use until the event is Grade 1 or less, then taper over 3 days.	Administer dexamethasone 10 mg IV every 6 hours. Continue dexamethasone use until the event is Grade 1 or less, then taper over 3 days.
Grade 4	Administer tocilizumab as outlined in previous chart for management of Grade 2 CRS. Administer methylprednisolone 1,000 mg IV with the first dose of tocilizumab and continue 1,000 mg IV/day for 2 more days; if improves to Grade 2 or 3, then manage as outlined above.	Administer methylprednisolone 1,000 mg IV per day for 3 days; if improves to Grade 2 or 3, then manage as outlined above.

Patient Education:

Read the FDA-approved patient medication guide. ■ Discuss all your medical problems and all medications, including prescription and over-the-counter medications, with your health care provider. ■ Patients must remain at the certified health care facility and be monitored daily for at least 7 days, and patients are to remain within proximity of the certified health care facility for at least 4 weeks after infusion. ■ Periodic monitoring of blood counts is required. ■ Seek immediate medical attention for S/S of CRS (e.g., chills, fatigue, fever, nausea, tachycardia, hypotension, hypoxia). ■ Promptly report S/S of infection (e.g., fever, chills). ■ Promptly report difficulty breathing; dizziness; fast or irregular heartbeat; severe fatigue or weakness; severe nausea, vomiting, or diarrhea; and unusual bleeding or bruising. ■ Promptly report S/S of neurologic toxicities (e.g., changes in level of consciousness, confusion, encephalopathy, speech disorders, seizures, tremors). Refrain from driving and engaging in hazardous occupations or activities for at least 8 weeks after the infusion. ■ Effective contraception is recommended for patients receiving lymphodepleting chemotherapy. See cyclophosphamide and fludarabine monographs for additional information. ■ Inform any health care provider treating you that you have received axicabtagene ciloleucel.

Maternal/Child:

Not recommended for women who are pregnant, and pregnancy after the infusion should be discussed with the treating physician. Based on the mechanism of action, transduced cells that cross the placenta may cause fetal toxicity, including B-cell lymphocytopenia. ■ Verify pregnancy status of females with reproductive potential by testing for pregnancy before starting treatment with axicabtagene ciloleucel. ■ Safety for use during breast-feeding not established; effects unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger subjects.

DRUG/LAB INTERACTIONS

Safety of immunization with live virus vaccines during or after treatment with axicabtagene ciloleucel has not been studied. Vaccination with live virus vaccines is not recommended for at least 6 weeks before the start of lymphodepleting chemotherapy, during treatment, and until immune recovery after treatment. ■ Specific information on drug/lab interactions not available.

SIDE EFFECTS

Cardiac arrhythmias, chills, constipation, cough, cytokine release syndrome, decreased appetite, diarrhea, dizziness, encephalopathy, fatigue, febrile neutropenia, fever, headache, hypotension, hypoxia, infections (pathogen unspecified), nausea, tachycardia, tremor, and vomiting are the most common nonlaboratory adverse reactions. The most common serious adverse reactions include aphasia, cardiac arrest, cardiac arrhythmia, cardiac failure, *Clostridium difficile* infection, delirium, encephalopathy, febrile neutropenia, fever, hypotension, hypoxia, lung infection, renal insufficiency, and urinary tract infection. Laboratory abnormalities include anemia; hypokalemia; hyponatremia; hypophosphatemia; increased ALT, direct bilirubin, and uric acid; leukopenia; lymphopenia; neutropenia; and thrombocytopenia. Potentially serious reactions include cytokine release syndrome, hypersensitivity reactions, hypogammaglobulinemia, infections, neurologic toxicities, and prolonged cytopenias. Numerous other side effects were reported in at least 10% of patients.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Treat side effects aggressively according to the grading and management charts in Monitor. Treat severe or life-threatening CRS with tocilizumab or tocilizumab and corticosteroids. Patients who experience Grade 2 or higher CRS (e.g., hypotension, no response to fluids, or hypoxia requiring supplemental oxygenation) or Grade 2 or higher neurologic toxicities should be monitored with continuous cardiac telemetry and pulse oximetry. Consider intensive care supportive therapy for severe or life-threatening CRS or neurologic toxicities. Consider nonsedating, antiseizure medicines (e.g., levetiracetam) for seizure prophylaxis for any Grade 2 or higher neurologic toxicities. Treat hypersensitivity reactions as necessary (e.g., antihistamines, epinephrine, corticosteroids). Resuscitate if indicated.

AZACITIDINE

(ay-za-**SYE**-ti-deen)
Vidaza
Antineoplastic
Antimetabolite

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

Prophylactic administration of antiemetics (e.g., granisetron, ondansetron [Zofran]) is indicated before each dose.

First treatment cycle:

An initial dose of 75 mg/M² as an IV infusion or as a SC injection once daily for 7 days is recommended for all patients regardless of baseline hematology.

Subsequent treatment cycles:

Cycles should be repeated every 4 weeks. Dose may be increased to 100 mg/M² if no beneficial effect is seen after 2 treatment cycles and if no toxicity other than nausea and vomiting has occurred. Treatment is recommended for a minimum of 4 to 6 cycles; however, a complete or partial response may require additional treatment cycles. Repeat cycles may be administered as long as the patient continues to benefit. See Dose Adjustments for dose delay or reduction recommendations for hematologic response, renal toxicities, and/or electrolyte disturbances.

DOSE ADJUSTMENTS

After administration of the recommended dosage for the first cycle, adjust dosage for subsequent cycles based on nadir counts and hematologic response as outlined in the following chart.

<table>
<tr><th colspan="4">Dose Adjustments of Azacitidine Based on Baseline Hematologic Responses</th></tr>
<tr><td colspan="4">In any given subsequent cycle for patients with a baseline (start of treatment) WBC equal to or greater than 3 × 10^9/L (3,000 cells/mm^3), ANC equal to or greater than 1.5 × 10^9/L (1,500 cells/mm^3), and platelets equal to or greater than 75 × 10^9/L (75,000 cells/mm^3): Adjust the dose based on nadir counts according to the following chart.</td></tr>
<tr><td colspan="2">Nadir Counts</td><td colspan="2">% Dose in the Next Cycle</td></tr>
<tr><td>ANC (cells/mm^3)</td><td></td><td colspan="2">Platelets (cells/mm^3)</td></tr>
<tr><td><500 cells/mm^3</td><td><25,000 cells/mm^3</td><td colspan="2">50%</td></tr>
<tr><td>500 to 1,500 cells/mm^3</td><td>25,000 to 50,000 cells/mm^3</td><td colspan="2">67%</td></tr>
<tr><td>>1,500 cells/mm^3</td><td>≥50,000 cells/mm^3</td><td colspan="2">100%</td></tr>
<tr><td colspan="4">In any given subsequent cycle for patients with a baseline (start of treatment) WBC less than 3 × 10^9/L (3,000 cells/mm^3), ANC less than 1.5 × 10^9/L (1,500 cells/mm^3), or platelets less than 75 × 10^9/L (75,000 cells/mm^3): Adjust the dose based on nadir counts and bone marrow biopsy cellularity at the time of the nadir according to the following chart. <i>The exception is the presence of clear improvement in differentiation (% of mature granulocytes is higher and ANC is higher than at the onset of that course) at the time of the next cycle. If this improvement occurs, the dose of the current treatment should be continued.</i></td></tr>
<tr><td rowspan="2">WBC or Platelet Nadir (% Decrease in Counts from Baseline)</td><td colspan="3">Bone Marrow Biopsy Cellularity at Time of Nadir (%)</td></tr>
<tr><td>30% to 60%</td><td>15% to 30%</td><td><15%</td></tr>
<tr><td></td><td colspan="3">% Dose in the Next Course</td></tr>
<tr><td>50% to 75%</td><td>100%</td><td>50%</td><td>33%</td></tr>
<tr><td>>75%</td><td>75%</td><td>50%</td><td>33%</td></tr>
</table>

If a nadir as defined in this chart has occurred, give the next course 28 days after the start of the preceding course, provided that both the WBC and the platelet count are greater than 25% above the nadir and are rising. If a greater than 25% increase above the nadir is not seen by Day 28, counts should be reassessed every 7 days. If a 25% increase is not seen by Day 42, reduce the scheduled dose by 50%.

Dose adjustments of azacitidine based on renal toxicity and serum electrolytes:

If unexplained reductions in serum bicarbonate levels to less than 20 mEq/L occur, reduce the dose by 50% on the next course. ■ If unexplained elevations of BUN or SCr occur, delay the next cycle until values return to baseline and then reduce the dose by 50% on the next course. Severe renal impairment (CrCl less than 30 mL/min) has no major effect on exposure of azacitidine after multiple SC administrations. Therefore azacitidine can be administered to patients with renal impairment without Cycle 1 dose adjustment. (IV route was not studied.) ■ Use care in dose selection for the elderly; reduced doses may be indicated based on overall renal function.

DILUTION

Specific techniques required; see Precautions.

Available as a lyophilized powder in single-use vials containing 100 mg. More than one vial may be required for a single dose. Reconstitute each vial with 10 mL SWFI. Vigorously shake or roll each vial until all solids are dissolved. Solution equals 10 mg/mL. Withdraw the required amount of azacitidine to deliver the desired dose and inject into a 50- or 100-mL infusion bag of NS or LR. Administration must be complete within 1 hour of reconstitution. Discard unused portions appropriately.

Filters:

Specific information not available.

Storage:

Store in cartons at CRT. Reconstituted solutions may be held at 25° C (77° F), but administration must be complete within 1 hour of reconstitution.

COMPATIBILITY

Manufacturer lists azacitidine as **incompatible** with D5W, hetastarch, or any solution that contains bicarbonate. These solutions have the potential to increase the rate of degradation of azacitidine.

RATE OF ADMINISTRATION

A single dose equally distributed over 10 to 40 minutes. Administration must be complete within 1 hour of reconstitution.

ACTIONS

A pyrimidine nucleoside analog of cytidine. Azacitidine is believed to exert its antineoplastic effects by causing hypomethylation of DNA and direct cytotoxicity on abnormal hematopoietic cells in the bone marrow. Cytotoxic effects cause the death of rapidly dividing cells, including cancer cells that are no longer responsive to normal growth-control mechanisms. Nonproliferating cells are relatively insensitive to azacitidine. This hypomethylation of DNA may restore normal function to genes that are critical for cellular differentiation and proliferation. May be metabolized by the liver. Half-life is 4 hours. Primarily excreted in urine with minimal excretion in feces.

INDICATIONS AND USES

Treatment of patients with the following French-American-British (FAB) myelodysplastic syndrome (MDS) subtypes such as refractory anemia (RA), refractory anemia with ringed sideroblasts (if accompanied by neutropenia or thrombocytopenia or requiring transfusions), refractory anemia with excess blasts (RAEB), refractory anemia with excess blasts in transformation (RAEB-T), and chronic myelomonocytic leukemia (CMMoL).

CONTRAINDICATIONS

Known hypersensitivity to azacitidine. ■ Patients with advanced malignant hepatic tumors.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A, p. 1308. ■ If azacitidine comes into contact with skin, immediately wash with soap and water. If it comes into contact with mucous membranes, flush thoroughly with water. ■ Administer by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Use caution in patients with liver disease; potentially hepatotoxic in patients with severe pre-existing hepatic impairment; see Contraindications. Cases of progressive hepatic coma and death have been reported in patients with extensive tumor burden due to metastatic disease, especially when baseline albumin is less than 3 Gm/dL. ■ Reports of renal abnormalities (e.g., elevated serum creatinine, renal failure, and death) have occurred in patients treated with azacitidine in combination with other chemotherapeutic agents for non-MDS conditions. Patients with renal impairment may be at increased risk for renal toxicity. ■ Renal tubular acidosis (a fall in serum bicarbonate to less than 20 mEq/L in association with an alkaline urine and hypokalemia [serum potassium less than 3 mEq/L]) developed in 5 patients with chronic myelogenous leukemia (CML) (an unapproved use) treated with azacitidine and etoposide. ■ May cause fatal or serious tumor lysis syndrome (TLS), including in patients with MDS; may occur despite concomitant use of uric acid–lowering drugs (e.g., allopurinol [Aloprim]). ■ The effects of age, race, gender, or hepatic impairment on the pharmacokinetics of azacitidine have not been studied. ■ Anemia, neutropenia, and thrombocytopenia may be dose-limiting toxicities.

Monitor:

Verify pregnancy status of females of reproductive potential before initiating azacitidine. ■ Obtain a baseline CBC with platelets, and monitor before each dosing cycle and as indicated to monitor response and toxicity between cycles. ■ Obtain baseline renal and hepatic function (BUN, SCr, LFT, bilirubin) studies and electrolytes; monitor with each cycle and during treatment as indicated. ■ Monitor for tumor lysis syndrome. Monitor uric acid levels and maintain hydration. Uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may be indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting and to increase patient comfort. ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccine to immunocompromised patients. ■ See Precautions and Antidote.

Patient Education:

Avoid pregnancy; effective contraception required for females of reproductive potential during treatment and for 6 months after the final dose. Effective contraception required for males with female partners of reproductive potential during treatment and for 3 months after the final dose. ■ Patients should report a suspected pregnancy immediately. ■ Azacitidine may have an effect on male or female fertility. ■ Inform physician about any underlying liver or renal disease.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. ■ Discontinue breast-feeding during treatment and for 1 week after the final dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar to younger adults. ■ Consider age-related renal impairment; dosing should be cautious; see Dose Adjustments. Monitor renal function.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been completed. ■ Effect on metabolism by some known microsomal enzyme inhibitors or inducers has been studied in vitro. Does not appear to inhibit CYP2B6 or CYP2C8. Potential to inhibit other CYP enzymes is not known. Does not appear to induce CYP1A2, CYP2C19, or CYP3A4/5. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Hypokalemia, petechiae, rigors, and weakness are the most common side effects. Other common side effects include anemia; constipation; diarrhea; ecchymosis; fever; injection site bruising, erythema, and pain; leukopenia; nausea; neutropenia; thrombocytopenia; and vomiting. Febrile neutropenia, fever, leukopenia, neutropenia, pneumonia, and thrombocytopenia were the most frequent cause of dose reduction, delay, and discontinuation. Infusion site erythema or pain and catheter site reactions such as infection, erythema, or hemorrhage were reported with IV administration. Elevated SCr, hepatic coma, hypokalemia, renal failure, renal tubular acidosis, and tumor lysis syndrome have also been reported. Numerous other side effects may be associated with azacitidine.

Post-Marketing:

Injection site necrosis, interstitial lung disease, necrotizing fasciitis (including fatal cases), Sweet's syndrome (acute febrile neutrophilic dermatosis), tumor lysis syndrome.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Dose may be reduced or delayed for hematologic toxicity, renal toxicity, or electrolyte disturbances. See Dose Adjustments for specific criteria. Blood and blood products, antibiotics, and other adjunctive therapies must be available. No known antidote; monitor blood counts and provide supportive care in overdose. Resuscitate as necessary.

AZATHIOPRINE SODIUM BBW

(ay-zah-**THIGH**-oh-preen **SO**-dee-um)
Immunosuppressant
pH 9.6

USUAL DOSE

Pretreatment:

Verify pregnancy status.

Azathioprine:

Initial dose:

3 to 5 mg/kg of body weight/24 hr beginning at the time of renal homotransplantation. Usually given as a single daily dose on the day of and, in a minority of cases, 1 to 3 days before transplantation.

Maintenance dose:

1 to 3 mg/kg/24 hr. Individualized dosing to prevent rejection and minimize toxicity is imperative. Do not increase to toxic levels because of threatened rejection. Oral and IV doses are therapeutically equivalent; transfer to oral therapy as soon as practical.

DOSE ADJUSTMENTS

Dose reduction to maintenance levels of 1 to 3 mg/kg daily is usually possible. ■ Dose reduction is recommended in patients with heterozygous deficiency of thiopurine *S*-methyltransferase (TPMT) and/or nucleotide diphosphatase (NUDT15); see Precautions. ■ Relatively oliguric patients, especially those with tubular necrosis in the immediate postcadaveric transplant period, may have delayed clearance of azathioprine or its metabolites and require lower doses. ■ Dose reduction may be required if there is a rapid fall or a persistently low leukocyte count. ■ Decrease dose to one-third to one-fourth of the usual dose when given concomitantly with allopurinol. Consider further dose reduction or alternative therapy in patients with low or absent TPMT activity who are receiving both drugs. ■ To minimize risk of malignancy secondary to immunosuppression, immunosuppressive drug therapy should be maintained at the lowest effective levels. ■ See Drug/Lab Interactions and Precautions/Monitor.

DILUTION

Specific techniques suggested; see Precautions. Each 100 mg should be initially reconstituted with 10 mL of SWFI. Swirl the vial gently until completely in solution. Further dilution with sterile saline or dextrose is usually made for infusion; final volume depends on duration of infusion.

Storage:

Store unopened vials at 20° to 25° C (68° to 77° F). Protect from light. Use diluted solution within 24 hours.

COMPATIBILITY

Listed as **incompatible** with preservatives (e.g., methylparaben, phenol, propylparaben). Manufacturer recommends administering separately. Converts to 6-mercaptopurine in alkaline solutions and sulfhydryl compounds. Flush IV line with a

compatible IV fluid before and after administration.

RATE OF ADMINISTRATION

A single dose properly diluted and infused over 30 to 60 minutes. Actual range may be 5 minutes to 8 hours.

ACTIONS

An immunosuppressive antimetabolite that aids in inhibition of renal homograft rejection. It is chemically cleaved to the antineoplastic compound 6-mercaptopurine. Exact method of action is unknown. It suppresses hypersensitivities of the cell-mediated type and causes variable alterations in antibody production. Action depends on the temporal relationship to antigenic stimulus or engraftment. Has little effect on established graft rejections or secondary responses. Also suppresses disease manifestations and underlying pathology of autoimmune disease (e.g., rheumatoid arthritis [RA]). Exact mechanism of action is unknown. Metabolized readily with small amounts excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunct to prevent rejection in renal homotransplantation. ■ Used PO to treat rheumatoid arthritis; see package insert.

CONTRAINDICATIONS

Known hypersensitivity to azathioprine. ■ Patients with rheumatoid arthritis who have been treated with alkylating agents (e.g., chlorambucil [Leukeran], cyclophosphamide [Cytoxan], melphalan [Alkeran]) may have a prohibitive risk of malignancy if treated with azathioprine. ■ Should not be used for treating rheumatoid arthritis in pregnant women.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents; see Appendix A. ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ Chronic immunosuppression increases the risk of malignancy. Reports of malignancy include posttransplant lymphoma, other malignancies (particularly of the skin), and hepatosplenic T-cell lymphoma (HSTCL) in patients with inflammatory bowel disease. Patients with Crohn's disease or inflammatory bowel disease, particularly adolescents and young adults, may have a higher risk of malignancies, including hepatosplenic T-cell lymphoma (HSTCL), with azathioprine alone or in combination therapy with TNF blockers (e.g., infliximab [Remicade]). Safety and efficacy of azathioprine for treatment of Crohn's disease and ulcerative colitis have not been established. ■ Has mutagenic potential to both men and women. ■ Severe leukopenia, thrombocytopenia, anemias including macrocytic anemia, and/or pancytopenia may occur. Hematologic toxicities are dose-related and may be more severe in renal transplant patients whose homograft is undergoing rejection. ■ Patients with TPMT or NUDIT15 deficiency may be at an increased risk for severe and life-threatening myelotoxicity if receiving conventional doses of azathioprine. Death associated with pancytopenia has been reported. ■ Serious infections (bacterial, fungal, protozoal, viral, and opportunistic infections, including reactivation of latent infections) may occur and can be fatal. ■ Progressive multifocal leukoencephalopathy (PML) has been reported in patients treated with immunosuppressants, including azathioprine. Deaths have occurred. ■ A GI hypersensitivity reaction characterized by severe nausea and vomiting has been reported. May also cause diarrhea, elevations of liver function tests, fever, hypotension, malaise, myalgias, and rash. Usually develops within the first several weeks of therapy and resolves when azathioprine is discontinued.

Monitor:

Monitor CBC with platelets weekly for the first month, twice monthly for the second and third months, then monthly or more frequently if dose adjustments or other therapy changes are necessary. Drug should be temporarily withdrawn or dose reduced if there is a rapid fall in or a persistently low leukocyte count or other evidence of bone marrow suppression. ■ In patients with severe myelosuppression, consider evaluation for TPMT and NUDT15 deficiency. Genotyping or phenotyping may help identify these patients. Accurate phenotyping results are not possible in patients who have received recent blood transfusions. Consider alternative therapy in patients with homozygous TPMT or NUDT15 deficiency and reduced dosages in patients with heterozygous deficiency. TPMT and NUDT15 testing cannot substitute for required CBC and platelet monitoring. ■ Observe constantly for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for S/S of malignancies. ■ Periodic assessment of liver function tests indicated for early detection of hepatotoxicity. ■ Consider PML in patients with new-onset or changes to pre-existing neurologic manifestations; consider consultation with a neurologist as clinically indicated. Consider dose reduction; however, reduced immunosuppression may cause graft rejection.

Patient Education:

Avoid pregnancy; effective birth control recommended. ■ Promptly report abdominal pain, fever, unusual bruising or bleeding, and/or S/S of infection. ■ Obtain all lab work as directed. ■ Wear protective clothing and use sunscreen to limit exposure to sunlight and ultraviolet light. ■ Risk of malignancy increased with chronic immunosuppression. ■ See Appendix D.

Maternal/Child:

Category D: avoid pregnancy. Can cause fetal harm. Should not be given during pregnancy without careful consideration of risk versus benefit; see Contraindications. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Dose selection should be cautious; consider age-related renal impairment; see Dose

Adjustments. Monitor renal function.

DRUG/LAB INTERACTIONS

Xanthine oxidase inhibitors (e.g., allopurinol [Aloprim] and febuxostat [Uloric]) inhibit the metabolism of azathioprine, increasing its activity and toxicity. Reduce dose of azathioprine to one-third or one-fourth of usual when administered concomitantly with allopurinol. Concomitant use with febuxostat is not recommended; see Dose Adjustments. ■ Inhibits anticoagulant effects of **warfarin** (Coumadin). ■ Concurrent use with **bone marrow suppressants, radiation therapy, other immunosuppressants** (e.g., cyclosporine [Sandimmune]) **or other drugs that may cause blood dyscrasias** (e.g., sulfamethoxazole/trimethoprim [Bactrim]) may increase toxicity. ■ Concurrent use with **ACE inhibitors** (e.g., captopril) may induce anemia and severe leukopenia. ■ **Aminosalicylates** (e.g., sulfasalazine [Azulfidine], mesalamine [Asacol, Pentasa], olsalazine [Dipentum]) may inhibit TPMT, increasing the risk of toxicity. Use caution if concomitant therapy is required. ■ **Ribavirin** (Rebetol, Vizoral) inhibits azathioprine metabolism. Concurrent use may induce severe pancytopenia. Dose adjustment and careful monitoring required if concurrent use necessary. ■ Antibody response to **vaccines** may be suppressed. Do not use **live virus vaccines** in patients receiving azathioprine.

SIDE EFFECTS

Principal and potentially serious side effects are hematologic and gastrointestinal. Risk of infection and malignancy are also significant. Frequency and severity of side effects depend on dose, duration of therapy, and on patient’s underlying condition and concomitant therapy. Leukopenia and/or thrombocytopenia are dose-dependent and dose limiting. Other side effects include alopecia; anemia; anorexia; arthralgia; bleeding; diarrhea; fever; hepatic veno-occlusive disease; hepatosplenic T-cell lymphoma; hepatotoxicity characterized by elevation of serum alkaline phosphatase, bilirubin, and serum transaminases (e.g., ALT, AST); hypotension; infection; jaundice; malaise; myalgias; nausea; neoplasia; oral lesions; pancreatitis; skin rash; Sweet’s syndrome (acute febrile neutrophilic dermatosis); vomiting. A GI hypersensitivity reaction has been reported; see Precautions.

ANTIDOTE

Notify the physician of all side effects. Most can be treated symptomatically and may reverse with dose reduction or discontinuation. The GI hypersensitivity reactions can occur within hours of a rechallenge. Hematopoietic depression may require temporary or permanent discontinuation of treatment and may be indicated even if rejection of graft may occur. Dialysis may be useful in overdose (partially dialyzable).

AZITHROMYCIN

(az-**zith**-roh-**MY**-sin)
Zithromax
Antibacterial (macrolide)

USUAL DOSE

Community-acquired pneumonia:

500 mg as a single daily dose for a minimum of 2 days. Follow with 500 mg of oral azithromycin as a single daily dose. Total course of therapy (IV + oral) should be 7 to 10 days.

Pelvic inflammatory disease:

500 mg as a single daily dose for 1 to 2 days. Follow with 250 mg of oral azithromycin as a single daily dose. Total course of therapy (IV + oral) should be 7 days. If anaerobic microorganisms are also suspected, concurrent administration of an antibacterial agent with anaerobic activity is recommended (e.g., metronidazole [Flagyl]).

DOSE ADJUSTMENTS

No dose adjustment provided by manufacturer for patients with impaired liver or renal function; see Precautions. ■ See Drug/Lab Interactions.

DILUTION

Each 500-mg vial must be reconstituted with 4.8 mL SWFI. Shake well to ensure dilution (100 mg/mL). Further dilute each 500 mg of reconstituted solution with 250 to 500 mL of one of the following solutions: D5W, NS, $^1/_2$NS, D5/$^1/_3$NS, D5/$^1/_2$NS, D5/$^1/_2$NS with 20 mEq KCl, LR, D5LR, D5/Normosol M, D5/Normosol R. 500 mL diluent yields 1 mg/mL, 250 mL yields 2 mg/mL. Concentrations greater than 2 mg/mL have caused local IV site reactions and should be avoided.

Storage:

Store vials at or below 30°C (86°F). Reconstituted or diluted solution stable at CRT for 24 hours. Diluted solution stable for up to 7 days if refrigerated.

COMPATIBILITY

Manufacturer states, “Other IV substances, additives, or medications should not be added to azithromycin, or infused simultaneously through the same IV line.” Flush IV line with a **compatible** IV fluid before and after administration.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not give by IV bolus; must be infused over at least 1 hour.

1 mg/mL dilution:

A single dose equally distributed over 3 hours.

2 mg/mL dilution:

A single dose equally distributed over 1 hour.

ACTIONS

A macrolide antibiotic. Active against selected organisms, including aerobic gram-positive and gram-negative organisms and other organisms, including *Chlamydia* and *Mycoplasma pneumoniae*. Interferes with microbial protein synthesis by binding a ribosomal subunit of a susceptible microorganism. Terminal half-life of 68 hours allows for once-daily dosing. Prolonged half-life is thought to result from extensive uptake and subsequent release of drug from tissues. Studies to assess the metabolism of azithromycin have not been performed. Excreted primarily as unchanged drug in bile. Up to 14% excreted in urine within 24 hours. Excreted in breast milk in small amounts.

INDICATIONS AND USES

Treatment of community-acquired pneumonia and pelvic inflammatory disease caused by susceptible strains of specific organisms (e.g., *Staphylococcus aureus, Streptococcus pneumoniae, Haemophilus influenzae, Legionella pneumophila, Neisseria gonorrhoeae, Chlamydia trachomatis*. See product insert for complete list of organisms). Administered to patients who require initial IV therapy. Many other indications for oral use.

CONTRAINDICATIONS

Hypersensitivity to any macrolide antibiotic. ■ Patients with a history of cholestatic jaundice/hepatic dysfunction associated with prior use of azithromycin.

PRECAUTIONS

For IV use only. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to azithromycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, azithromycin should be used only to treat infections proven or strongly suspected to be caused by susceptible bacteria. ■ Has demonstrated cross-resistance with erythromycin. ■ Serious hypersensitivity reactions, including angioedema, anaphylaxis, dermatologic reactions (e.g., acute generalized exanthematous pustulosis [AGEP], Stevens-Johnson syndrome, toxic epidermal necrolysis), and cases of drug reaction with eosinophilia and systemic symptoms (DRESS), have been reported. Use extreme caution; hypersensitivity reactions have recurred even after azithromycin was discontinued and hypersensitivity reactions treated. Fatalities have been reported. ■ Hepatotoxicity, including abnormal liver function, hepatitis, cholestatic jaundice, hepatic necrosis, and hepatic failure, have been reported; deaths have occurred. The pharmacokinetics of azithromycin in patients with hepatic impairment has not been established. ■ Use caution in patients with impaired renal function. Data unavailable. ■ Macrolide antibiotics (including azithromycin) have caused prolonged cardiac repolarization and QT intervals, imparting a risk of developing cardiac arrhythmia and torsades de pointes, which can be fatal. Consider risk/benefit of azithromycin use in at-risk patients, such as patients with known prolonged QT intervals; a history of torsades de pointes, congenital long QT syndrome, bradyarrhythmias, or uncompensated heart failure; patients taking drugs known to prolong the QT interval; patients with ongoing pro-arrhythmic conditions (e.g., uncorrected hypokalemia or hypomagnesemia) or clinically significant bradycardia; and patients receiving Class Ia (quinidine, procainamide) or Class III (amiodarone, dofetilide, sotalol) antiarrhythmic agents. ■ Timing of transfer to oral therapy should be based on clinical response. ■ Avoid prolonged use; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with azithromycin. ■ May cause exacerbations of symptoms of myasthenia gravis or new onset of myasthenia syndrome.

Monitor:

Monitor vital signs. ■ Observe closely for signs of a hypersensitivity reaction; see Antidote. ■ Monitoring of liver function may be indicated; see Precautions. ■ ECG monitoring for QT prolongation may be indicated; see Precautions. ■ Monitor infusion site for inflammation and/or extravasation. ■ Contains 4.96 mEq of sodium/vial. Observe for electrolyte imbalance and cardiac irregularities. May aggravate CHF. ■ See Drug/Lab Interactions and Antidote.

Patient Education:

Discontinue azithromycin and report any signs of an allergic reaction immediately (difficulty breathing, itching, rash, swelling). ■ Discontinue azithromycin and report S/S of hepatitis (e.g., dark urine, jaundice, loss of appetite, malaise, nausea and vomiting). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Parents or caregivers of neonates who have received azithromycin should report vomiting or irritability with feedings. ■ Review all prescription and nonprescription medications with your health care provider.

Maternal/Child:

Safety for use during pregnancy not established; use with caution and only if clearly needed. Available data do not suggest an increased risk for major birth defects, miscarriage, or adverse maternal or fetal outcomes with azithromycin use in pregnant women. ■ Azithromycin is present in human milk. Monitor breast-fed infant for diarrhea, vomiting, or rash. ■ Safety and effectiveness of IV formulation for use in pediatric patients under 16 years of age not established. ■ Infantile hypertrophic pyloric stenosis (IHPS) has been reported after the use of azithromycin in neonates (treatment up to 42 days of life). Caregivers should contact their physician if vomiting or irritability with feeding occurs. ■ Has been administered to pediatric patients age 6 months to 16 years by the oral route. The most common side effects in this age-group included abdominal pain, diarrhea, headache, nausea, rash, and vomiting.

Elderly:

Response similar to that seen in younger adults. ■ May be more susceptible to development of drug-associated effects on the QT interval and torsades de pointes than younger patients. ■ May respond with a blunted natriuresis to salt loading; see Monitor. ■ Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

May increase the anticoagulant effects of **warfarin**; monitoring of PT is indicated. ■ Coadministration with **nelfinavir** results in increased azithromycin levels. Dose adjustment is not recommended, but close monitoring for known side effects (e.g., liver enzyme abnormalities, hearing impairment) is suggested. ■ May have a modest effect on the pharmacokinetics of **atorvastatin, carbamazepine, cetirizine, didanosine, efavirenz, fluconazole, indinavir, midazolam, nelfinavir, sildenafil, sulfamethoxazole/trimethoprim, theophylline, triazolam**, or **zidovudine**. No dose adjustment required with coadministration of these drugs. ■ **Efavirenz and fluconazole** may have a modest effect on the pharmacokinetics of azithromycin. No dose adjustment is necessary with coadministration of these drugs. Use caution when coadministered with **digoxin, colchicine**, or **phenytoin**. Interactions have not been reported in clinical trials with azithromycin, but studies have not been performed to evaluate potential drug-drug interactions. Drug interactions have been observed with these drugs and other macrolide antibiotics.

SIDE EFFECTS

Usually mild to moderate in severity and reversible after azithromycin discontinued. The most commonly reported side effects are abdominal pain, diarrhea, nausea and vomiting. Less frequently reported side effects include anorexia; dizziness; dyspnea; injection site pain or local inflammation; pruritus; rashes; stomatitis; vaginitis. Reported laboratory abnormalities include decreased platelet count; elevated AST, ALT, alkaline phosphatase, bilirubin, creatinine, LDH; leukopenia; and neutropenia.

Post-Marketing:

Arrhythmias (e.g., ventricular tachycardia, hypotension, QT prolongation, and torsades de pointes), asthenia, CDAD, CNS toxicity (e.g., agitation, convulsions, headache, hyperactivity, somnolence, syncope), constipation, dermatologic reactions (including acute generalized exanthematous pustulosis [AGEP], pruritus, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria), DRESS, dyspepsia, fatigue, hearing disturbances (including hearing loss, deafness, and/or tinnitus), hepatotoxicity (e.g., hepatitis and cholestatic jaundice, cases of hepatic necrosis, and hepatic failure [some resulting in death]), hypersensitivity reactions (e.g., anaphylaxis, angioedema), interstitial nephritis, malaise, oral candidiasis, pancreatitis, paresthesia, pyloric stenosis, acute renal failure, and taste/smell perversion and/or loss.

ANTIDOTE

Notify physician of any side effects. Discontinue azithromycin for hypersensitivity reactions and S/S of hepatotoxicity. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Hypersensitivity reactions have recurred after azithromycin has been discontinued and initial treatment completed. Prolonged observation is required. Mild cases of CDAD may respond to discontinuation of azithromycin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated.

AZTREONAM

(az-**TREE**-oh-nam)
Azactam
Antibacterial (monobactam)
pH 4.5 to 7.5

USUAL DOSE

Pretreatment:

See Precautions.

Dose and route determined by susceptibility of the causative organism(s), severity and site of infection, and condition of the patient. IV route recommended for patients requiring single doses greater than 1 Gm or those with bacterial septicemia, localized parenchymal abscess (e.g., intra-abdominal abscess), peritonitis, or other severe systemic or life-threatening infections.

Urinary tract infection:

500 mg to 1 Gm every 8 or 12 hours.

Moderately severe systemic infections:

1 or 2 Gm every 8 or 12 hours.

Severe systemic or life-threatening infections:

2 Gm every 6 or 8 hours. Use the full suggested dose. Do not exceed 8 Gm/24 hr.

Normal renal function required. Duration of therapy depends on the severity of the infection. Continue for at least 2 days after all symptoms of infection subside. Can produce therapeutic serum levels given intraperitoneally in dialysis fluid.

PEDIATRIC DOSE

See Maternal/Child.

Mild to moderate infections:

30 mg/kg every 8 hours.

Moderate to severe infections:

30 mg/kg every 6 or 8 hours. Maximum recommended dose is 120 mg/kg/24 hr.

Cystic fibrosis:

50 mg/kg every 6 to 8 hours. Maximum dose is 200 mg/kg/day not to exceed 8 Gm/24 hr. Higher doses have been used.

NEONATAL DOSE

Neonatal doses are **unlabeled;** see Maternal/Child.
30 mg/kg/dose. Interval between doses based on age and weight as follows:

Less than 1,200 Gm and 0 to 4 weeks of age:

Give every 12 hours.

1,200 to 2,000 Gm and 0 to 7 days of age:

Give every 12 hours.

1,200 to 2,000 Gm and over 7 days of age:

Give every 8 hours.

More than 2,000 Gm and 0 to 7 days of age:

Give every 8 hours.

More than 2,000 Gm and over 7 days of age:

Give every 6 hours.

DOSE ADJUSTMENTS

Dosing in the elderly should be cautious and reduced based on CrCl; consider potential for decreased organ function and concomitant disease or drug therapy. ■ Prolonged serum levels may occur in patients with transient or persistent renal insufficiency. After an initial loading dose of 1 or 2 Gm, reduce succeeding doses by 50% in patients with CrCl between 10 and 30 mL/min/1.73 M^2. ■ After an initial loading dose of 500 mg, 1 Gm, or 2 Gm, reduce succeeding doses by 75% in patients with CrCl less than 10 mL/min/1.73 M^2 or in patients supported by dialysis. For serious or life-threatening infections, in addition to the maintenance doses, give 12.5% of the initial dose after each dialysis session.

DILUTION

Usually light yellow, may become slightly pink on standing; does not affect potency.

IV injection:

Reconstitute a single dose with 6 to 10 mL of SWFI. Shake immediately and vigorously. Use immediately and discard any unused solution.

Intermittent IV:

Initially reconstitute each single dose with a minimum of 3 mL of SWFI. Shake immediately and vigorously. Must be further diluted in at least 50 mL of D5W, NS, or other **compatible** infusion solutions for each 1 Gm of aztreonam (see chart on inside back cover or literature). Concentration should not exceed 20 mg/mL or 2% w/v. Available in vials and premixed Galaxy infusion bags.

Storage:

Store vials at RT before use. Concentrations exceeding 2% should be used promptly unless prepared with SWFI or NS. Other reconstituted or diluted solutions are stable for 48 hours at CRT or up to 7 days if refrigerated. Vials are for single use only; discard unused amounts. Store aztreonam in Galaxy plastic containers at or below −20° C (−4° F). Thaw frozen container at RT or in a refrigerator. **Do not** force thaw by immersion in a water bath or by microwave irradiation. Thawed solutions are stable for 14 days refrigerated or for 48 hours at RT. Do not refreeze.

COMPATIBILITY

Manufacturer lists as **incompatible** with metronidazole (Flagyl IV) and nafcillin (Nallpen).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose equally distributed over 3 to 5 minutes.

Intermittent IV:

A single dose over 20 to 60 minutes. May be given through Y-site. Do not infuse simultaneously with other drugs or solutions except in proven **compatibility**. Flush common IV tubing before and after administration.

ACTIONS

A synthetic monobactam antibiotic. Bactericidal through inhibition of bacterial cell wall synthesis to a wide spectrum of specific gram-negative aerobic organisms, including *Pseudomonas aeruginosa*. Has activity in the presence of some beta-lactamases (both penicillinases and cephalosporinases) of gram-negative and gram-positive bacteria. Widely distributed into many body fluids and tissues. Serum half-life averages 1.7 hours;

range is 1.5 to 2 hours. Primarily excreted in the urine with some excretion through feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, gynecologic, and intra-abdominal infections and bacterial septicemia. Most effective against specific gram-negative organisms (see literature). ■ Adjunctive therapy to surgery for the management of infections caused by susceptible organisms, including abscesses, infections complicating hollow viscus perforations, cutaneous infections, and infections of serous surfaces.

CONTRAINDICATIONS

Known hypersensitivity to aztreonam or its components.

PRECAUTIONS

Specific studies are indicated to identify the causative organism and susceptibility to aztreonam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, aztreonam should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Before C/S data are available, concurrent initial antimicrobial therapy with agents to cover gram-positive and/or anaerobic microorganisms may be indicated in seriously ill patients. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Can result in hypersensitivity reactions with or without prior exposure. ■ Cross-reactivity with other beta-lactam antibiotics (e.g., penicillins, cephalosporins, and/or carbapenems) is rare but can occur. Use with caution in patients with a history of hypersensitivity reactions to beta-lactam antibiotics. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with aztreonam. ■ Toxic epidermal necrolysis has been reported rarely in patients receiving aztreonam who have undergone BMT and have other risk factors (e.g., radiation therapy, sepsis).

Monitor:

Watch for early symptoms of a hypersensitivity reaction. Use caution in patients with known sensitivity to penicillins, cephalosporins, or carbapenems. ■ Monitor renal and hepatic function, especially in the elderly. ■ Monitor renal function with concurrent administration of higher doses or prolonged administration of aminoglycosides (e.g., gentamicin). ■ May cause thrombophlebitis. Use small needles and large veins and rotate infusion sites.

Patient Education:

Report pain or burning at injection site or S/S of a hypersensitivity reaction (e.g., difficulty breathing, flushing, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: use in pregnancy only if clearly needed. ■ Consider discontinuing breast-feeding. ■ Safety and effectiveness for use in pediatric patients between 9 months and 16 years of age has been established. ■ Safety and effectiveness for use in infants under 9 months of age and for treatment of pediatric patients with septicemia and skin and skin-structure infections (where the skin infection is believed or known to result from *H. influenzae* type b) not established. ■ Higher doses of aztreonam may be indicated in pediatric patients with cystic fibrosis. ■ IV route is suggested for pediatric patients; data are limited for IM injection and impaired renal function.

Elderly:

Reduced doses may be indicated. Monitor renal function; see Dose Adjustments. ■ Response is similar to that seen in younger patients; however, clearance is decreased and half-life is prolonged.

DRUG/LAB INTERACTIONS

Antagonism may occur with **beta-lactamase–inducing antibiotics** (e.g., cefoxitin, imipenem); do not use concurrently. ■ Aztreonam and **aminoglycosides** have been shown to be synergistic against many gram-negative aerobic bacilli. May be used concomitantly in severe infections. Nephrotoxicity and ototoxicity can be markedly increased when both drugs are utilized. ■ See Side Effects.

SIDE EFFECTS

Diarrhea, nausea and vomiting, phlebitis/thrombophlebitis, and rash occur most frequently. Less frequently reported reactions include abdominal cramps; altered taste; breast tenderness; CDAD (including pseudomembranous colitis); chest pain; confusion; diaphoresis; diplopia; dizziness; dyspnea; elevated alkaline phosphatase, AST, ALT, platelets, and SCr; encephalopathy; eosinophilia; erythema multiforme; exfoliative dermatitis; fever; flushing; GI bleeding; halitosis; headache; hematologic changes (e.g., anemia, leukocytosis, neutropenia, pancytopenia, thrombocytopenia, thrombocytosis); hepatitis; hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm); hypotension; insomnia; jaundice; malaise; mouth ulcer; muscular aches; nasal congestion; numb tongue; paresthesia; petechiae; positive Coombs' test; prolonged PT and PTT; pruritus; purpura; seizures; sneezing; tinnitus; toxic epidermal necrolysis; transient ECG changes (ventricular bigeminy and PVCs); urticaria; vaginal candidiasis; vaginitis; vertigo; weakness; wheezing.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or peritoneal dialysis may be useful in overdose.

*The Black Box Warning applies only to the generic formulation.

[a] Recombinant (Porcine Sequence [Obizur]) is indicated for use only in acquired hemophilia. Not indicated for use in congenital hemophilia A.

[a] See Index for monograph of Lymphocyte Immune Globulin, the equine product of Anti-Thymocyte Globulin.

BASILIXIMAB BBW

(**bah**-zih-**LIX**-ih-mab)
Simulect
Recombinant monoclonal antibody
Immunosuppressant

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Basiliximab should only be administered once it has been determined that the patient will receive the graft and concomitant immunosuppression. Patients who have received a previous course of basiliximab should only be re-exposed to a subsequent course of therapy with extreme caution. Used concurrently with cyclosporine (Sandimmune) and corticosteroids.

Organ rejection prophylaxis in renal transplant:

2 doses of 20 mg each as an infusion. Administer the first dose within 2 hours before transplantation. Give the second dose 4 days after transplantation. Withhold the second dose if complications such as severe hypersensitivity reactions to basiliximab or graft loss occur.

PEDIATRIC DOSE

Less than 35 kg:

2 doses of 10 mg each (discard remaining product after each dose).

35 kg or more:

2 doses of 20 mg each.

In all pediatric patients, administer the first dose within 2 hours before transplantation. Give the second dose 4 days after transplantation. See Actions and Maternal/Child. Withhold second dose if complications occur (e.g., hypersensitivity reactions or graft loss).

DOSE ADJUSTMENTS

No dose adjustments indicated.

DILUTION

Reconstitute each single 20-mg vial with 5 mL of SWFI. Reconstitute each 10-mg vial with 2.5 mL SWFI. Shake gently to dissolve powder. After reconstitution, may be given as an IV injection or may be further diluted to 50 mL with NS or D5W. When mixing, gently invert to avoid foaming; do not shake.

Storage:

Store unopened vials in the refrigerator (2° to 8° C [36° to 46° F]). Should be used within 4 hours of reconstitution. If necessary, may be refrigerated for up to 24 hours. Discard prepared solution after 24 hours.

COMPATIBILITY

Manufacturer states, "Other drug substances should not be added or infused simultaneously through the same IV line." No **incompatibilities** observed with polyvinyl chloride bags and administration sets.

RATE OF ADMINISTRATION

May be given through a peripheral or central vein.

IV injection:

May be given as a bolus injection over 30 to 60 seconds. Incidence of N/V and local reaction including pain increased.

Infusion:

A single dose properly diluted over 20 to 30 minutes.

ACTIONS

A chimeric (murine/human) monoclonal antibody produced by recombinant DNA technology. Functions as an immunosuppressant. Specifically binds to and blocks the interleukin-2 receptor alpha chain (IL-2Rα, also known as CD25 antigen), thereby inhibiting IL-2 driven proliferation of activated T-cells, which play a key role in organ rejection. Reduces/minimizes acute rejection. IL-2Rα is expressed selectively on activated, but not resting, T-cells. This selectivity prevents the profound generalized immunosuppression seen with other immunosuppressants used in organ transplantation and may decrease the risk of infection and development of lymphoproliferative disorders. Two 20-mg doses block the receptor for 4 to 6 weeks posttransplantation, the critical risk period for acute organ rejection. Has reduced the incidence of biopsy-confirmed acute rejections while minimizing side effects seen with other immunosuppressants. Clinical benefit demonstrated in a broad range of patients, regardless of age, gender, race, donor type, or history of diabetes mellitus as long as serum levels exceed 0.2 mg/mL (by ELISA). Mean half-life is 4 to 10.4 days. Half-life is increased (5.2 to 17.8 days) and distribution volume and clearance are decreased by about 50% in pediatric patients 2 to 11 years of age. Crosses the placental barrier. May be secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of acute organ rejection in patients receiving renal transplants. Used as part of an immunosuppressive regimen that includes cyclosporine and corticosteroids. Dosing regimen may also include either azathioprine or mycophenolate (CellCept IV).

CONTRAINDICATIONS

Known hypersensitivity to basiliximab or any of its components (composite of human and murine antibodies).

PRECAUTIONS

Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. Adequate laboratory and supportive medical resources must be available. ■ Severe acute (onset within 24 hours) hypersensitivity reactions including anaphylaxis have been reported both with initial exposure and/or following re-exposure after several months. Emergency equipment and drugs for the treatment of severe hypersensitivity reactions must be readily available. Withhold the second dose of basiliximab if a hypersensitivity reaction occurs. ■ Readministration after an initial course of therapy has not been studied in humans, but other monoclonal antibodies have precipitated anaphylactoid reactions. ■ Potential for causing lymphoproliferative disorders, cytomegalovirus (CMV), and other opportunistic infections is unknown. ■ Use with caution in patients with infections or malignancies. ■ It is not known whether basiliximab use will have a long-term effect on the ability of the immune system to respond to antigens first encountered during induced immunosuppression. ■ Low titers of anti-idiotype antibodies and human antimurine antibodies (HAMA) to basiliximab have been detected in some patients during treatment; no adverse effects have been noted.

Monitor:

Obtain baseline CBC with differential and platelets and baseline renal and liver tests if not already completed for other immunosuppressant agents. ■ Monitor vital signs. ■ Observe closely for signs of infection (fever, sore throat, tiredness) or unusual bleeding or bruising. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile immunosuppressed patient. ■ Symptoms of cytokine release syndrome (e.g., chills, fever, dyspnea, and malaise) have not been reported but may occur; observe carefully. ■ See Drug/Lab Interactions.

Patient Education:

Report difficulty in breathing or swallowing, rapid heartbeat, rash, or itching immediately. ■ Report swelling of lower extremities and weakness. ■ Avoid pregnancy; women with childbearing potential should use effective contraception before beginning basiliximab therapy, during therapy, and for 2 months after completion. ■ See Appendix D, p. 1311.

Maternal/Child:

Category B: use during pregnancy only if benefits justify the potential risk to the fetus.

Avoid pregnancy; effective contraception required; see Patient Education. ■ Discontinue breast-feeding. ■ Has been used in pediatric patients from 2 to 15 years of age. No adequate or well-controlled studies completed. See differences in Actions. Most frequent side effects were fever and urinary infections.

Elderly:

Age-related dosing not required. Adverse events similar to younger adults. Use caution when giving immunosuppressive drugs to the elderly.

DRUG/LAB INTERACTIONS

Has been administered concurrently with **anti-lymphocyte globulin** (ALG), **anti-thymocyte globulin, azathioprine, corticosteroids, cyclosporine, muromonab CD3, and mycophenolate**; no additional adverse reactions noted. ■ **May increase or decrease numerous lab values,** including serum calcium and potassium and fasting blood glucose.

SIDE EFFECTS

Basiliximab did not appear to alter the pattern, frequency, or severity of known side effects associated with the use of immunosuppressive drugs. Abdominal pain, anemia, constipation, diarrhea, edema, fever, headache, hyperkalemia, hypersensitivity reactions (including anaphylaxis, bronchospasm, capillary leak syndrome, cardiac failure, cytokine release syndrome, dyspnea, hypotension, pruritus, pulmonary edema, rash, respiratory failure, sneezing, tachycardia, urticaria, wheezing), hypertension, hypokalemia, insomnia, nausea, pain, peripheral edema, upper respiratory infections, urinary tract infections. Incidence of N/V and local reaction including pain increased with bolus injection. Severe hypersensitivity reactions (including anaphylaxis), capillary leak syndrome, and cytokine release syndrome have been reported. Incidence of infections, lymphomas, or other malignancies similar to placebo groups in studies.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Basiliximab may be discontinued or alternate immunosuppressive agents substituted. Discontinue immediately if anaphylaxis occurs, and treat with oxygen, epinephrine, corticosteroids, and/or antihistamines. Resuscitate as necessary.

BELATACEPT BBW

(bel-**AT**-a-sept)
Nulojix
Immunosuppressant (selective T-cell costimulation blocker)
pH 7.2 to 7.8

USUAL DOSE

Pretreatment:

Ascertain Epstein-Barr virus (EBV) serology before treatment. Testing for latent TB indicated; see Contraindications and Monitor.

Administration of higher-than-recommended doses or more frequent dosing of belatacept is not recommended because of an increased risk of posttransplant lymphoproliferative disorder (PTLD), progressive multifocal leukoencephalopathy (PML), and serious CNS infections.

Premedication is not required. Base the total infusion dose on actual body weight at the time of transplantation.

Dosing of Belatacept for Kidney Transplant Recipients[a]	
Dosing for Initial Phase	**Dose**
Day 1 (day of transplantation, before implantation) and Day 5 (approximately 96 hours after Day 1 dose)	10 mg/kg
End of Week 2 and Week 4 after transplantation	10 mg/kg
End of Week 8 and Week 12 after transplantation	10 mg/kg
Dosing for Maintenance Phase	**Dose**
End of Week 16 after transplantation and every 4 weeks (plus or minus 3 days) thereafter	5 mg/kg

[a] The dose prescribed must be evenly divisible by 12.5 mg (evenly divisible increments are 0, 12.5, 25, 37.5, 50, 62.5, 75, 87.5, and 100). For example: At 10 mg/kg/dose, a patient weighing 64 kg would receive 640 mg. The closest doses evenly divisible by 12.5 below and above 640 mg are 637.5 mg and 650 mg. The nearest dose is 637.5 mg, and this would be the actual prescribed dose.

Regimen includes basiliximab (Simulect) induction, mycophenolate mofetil (MMF, CellCept), and corticosteroids.

Basiliximab:

20 mg IV on the day of transplantation and 4 days later.

Mycophenolate mofetil:

1 Gm twice daily as an initial dose. Adjust dose based on clinical signs of adverse events or efficacy failure.

Corticosteroid doses

should be consistent with those used in clinical trials. In Study 1 and Study 2, methylprednisolone 500 mg IV was given on arrival to the OR on Day 1. Methylprednisolone 250 mg IV was given on Day 2, and prednisone 100 mg PO was given on Day 3. In clinical trials, the median corticosteroid doses were tapered to approximately 15 mg (10 to 20 mg) per day by the first 6 weeks and remained at approximately 10 mg (5 to 10 mg) per day for the first 6 months posttransplant; see Precautions. Actual corticosteroid dosing in clinical trials is summarized in the following chart.

Actual Corticosteroid[a] Dosing in Studies 1 and 2		
Day of Dosing	Median (Q1-Q3) Daily Dose[b,c]	
	Study 1	Study 2
Week 1	31.7 mg (26.7 to 50 mg)	30 mg (26.7 to 50 mg)
Week 2	25 mg (20 to 30 mg)	25 mg (20 to 30 mg)
Week 4	20 mg (15 to 20 mg)	20 mg (15 to 22.5 mg)
Week 6	15 mg (10 to 20 mg)	16.7 mg (12.5 to 20 mg)
Month 6	10 mg (5 to 10 mg)	10 mg (5 to 12.5 mg)

[a] Corticosteroid = Prednisone or prednisolone.

[b] Protocols allowed for flexibility in determining corticosteroid dose and rapidity of taper after Day 15. It is not possible to distinguish corticosteroid doses used to treat acute rejection versus doses used in a maintenance regimen.

[c] Q1 and Q3 are the 25th and 75th percentiles of daily corticosteroid doses, respectively.

DOSE ADJUSTMENTS

Do not modify the dose during the course of therapy unless there is a change in body weight of greater than 10%. ■ Age, gender, race, renal function, hepatic function, diabetes, and concomitant dialysis do not affect the clearance of belatacept.

DILUTION

Belatacept is for IV infusion only. ***Must be reconstituted/prepared using only the silicone-free disposable syringe provided with each vial. This syringe will be required for both reconstitution and the preparation of the final infusion. Maintain sterility. Any solution prepared with other than the provided silicone-free syringe must be discarded.***

Each vial contains 250 mg of belatacept lyophilized powder. Calculate the number of vials needed to provide the total infusion dose. Reconstitute the contents of each vial with 10.5 mL of SWFI, NS, or D5W using the silicone-free disposable syringe and an 18- to 21-gauge needle. Direct the stream of diluent to the glass wall of the vial. To avoid foaming, rotate the vial and swirl gently until contents are completely dissolved. *Avoid prolonged or vigorous agitation. Do not shake.* Reconstituted solution yields 25 mg/mL and should be clear to slightly opalescent and colorless to pale yellow. Calculate the total volume of reconstituted solution required to provide the prescribed dose:

Volume of 25 mg/mL belatacept solution (in mL) = Prescribed dose (in mg) ÷ 25 mg/mL

The reconstituted solution must be further diluted in infusion fluid. If reconstituted with SWFI, dilute with either NS or D5W. If reconstituted with NS, further dilute with NS. If reconstituted with D5W, further dilute with D5W. From the appropriate-size infusion bag or bottle (typically an infusion volume of 100 mL is appropriate, but volumes from 50 to 250 mL may be used), withdraw a volume of infusion fluid equal to the total volume of reconstituted belatacept required to provide the prescribed dose. Using the same silicone-free disposable syringe used for reconstitution, withdraw the required amount of belatacept and inject it into the infusion bag or bottle. Gently rotate to ensure mixing. Concentration should range from 2 mg/mL to 10 mg/mL.

Filters:

Must be administered with a nonpyrogenic, low–protein-binding, 0.2- to 1.2-micron filter.

Storage:

Refrigerate vials of lyophilized powder at 2° to 8° C (36° to 46° F) in carton to protect from light. The reconstituted solution should be further diluted in infusion fluid immediately. The infusion must be completed within 24 hours. Infusion solution can be refrigerated protected from light for up to 24 hours. A maximum of 4 hours of those 24 hours can be at RT 20° to 25° C (68° to 77° F) and room light. Discard any unused solution remaining in vials.

COMPATIBILITY

Manufacturer states, "Must be reconstituted/prepared using only the silicone-free disposable syringe provided with each vial. Any solution prepared with other than the provided silicone-free syringe must be discarded" and "Infuse in a separate line; should not be infused concomitantly in the same IV line with other agents."

RATE OF ADMINISTRATION

A single dose evenly distributed over 30 minutes.

ACTIONS

A selective T-cell costimulation blocker. Produced by recombinant DNA technology. Binds to CD80 and CD86 on antigen-presenting cells, thereby blocking CD28-mediated costimulation of T-lymphocytes. Belatacept-mediated costimulation blockade results in the inhibition of cytokine production by T-cells required for antigen-specific antibody production by B-cells and inhibits T-lymphocyte proliferation. Activated T-lymphocytes are the predominant mediators of immunologic rejection. Half-life ranges from 6.1 to 15.1 days.

INDICATIONS AND USES

Prophylaxis of organ rejection in adult patients receiving a kidney transplant. Used in combination with basiliximab induction, mycophenolate mofetil, and corticosteroids.

Limitations of use:

Use only in patients who are Epstein-Barr virus (EBV) seropositive. ■ Use for prophylaxis of organ rejection in transplanted organs other than the kidney not established.

CONTRAINDICATIONS

Transplant recipients who are Epstein-Barr virus (EBV) seronegative or who have unknown EBV serostatus because of risk of posttransplant lymphoproliferative disorder (PTLD) predominantly involving the CNS.

PRECAUTIONS

For IV infusion only. ■ Usually administered by or under the direction of a physician experienced in immunosuppressive therapy and management of kidney transplant patients. Adequate laboratory and supportive medical resources must be available. ■ Increased risk for developing posttransplant lymphoproliferative disorder (PTLD), predominantly involving the CNS, compared with patients on a cyclosporine-based regimen. Recipients without immunity to Epstein-Barr virus (EBV) are at a particularly increased risk; therefore use in EBV-seropositive patients only. Do not use belatacept in transplant recipients who are EBV-seronegative or who have unknown EBV serostatus. ■ Other known risk factors for PTLD include cytomegalovirus (CMV) infection and T-cell–depleting therapy. Use T-cell–depleting therapies to treat acute rejection with caution. CMV prophylaxis is recommended for at least 3 months after transplantation. Patients who are EBV seropositive and CMV seronegative may be at increased risk for PTLD compared with patients who are EBV seropositive and CMV seropositive. ■ Minimization of the corticosteroid dose to 5 mg/day between Day 3 and Week 6 posttransplantation has been associated with an increased rate and grade of acute rejection, particularly Grade III rejection. Graft loss occurred in some patients. Corticosteroid use should be consistent with clinical trial experience; see Usual Dose. ■ Increased susceptibility to infection and possible development of malignancies may result from immunosuppression. Increased risk of developing other malignancies, including malignancies of the skin, appears related to intensity and duration of use. Avoid prolonged exposure to UV light and sunlight. Risk of developing bacterial, viral (e.g., CMV and herpes), fungal, and protozoal infections, including opportunistic infections such as tuberculosis (TB) or polyoma virus–associated nephropathy (PVAN), is increased and may lead to serious (including fatal) outcomes. Prophylaxis for *Pneumocystis jiroveci* is recommended after transplantation. ■ The coadministration (at the same or nearly the same time) of anti-thymocyte globulin and belatacept may pose a risk for venous thrombosis of the renal allograft; see Drug/Lab Interactions. ■ PML (a rapidly progressive and fatal opportunistic infection of the CNS that is caused by the JC virus) has been reported. ■ Infusion-related reactions have occurred within 1 hour of infusion; however, no serious reactions or anaphylaxis were reported in studies. ■ Use in liver transplant patients is not recommended because of an increased risk of graft loss and death. ■ Anti-belatacept antibody development was not associated with an altered clearance of belatacept. The clinical impact of anti-belatacept antibodies has not been determined. ■ Do not administer live virus vaccines; see Drug/Lab Interactions.

Monitor:

Ascertain EBV serology before starting therapy with belatacept. ■ Monitor for new or worsening neurologic, cognitive, or behavioral signs and symptoms. May indicate PTLD or PML. ■ PML is usually diagnosed by brain imaging, CSF testing for JC viral DNA, and/or brain biopsy. Consultation with a specialist (e.g., neurologist and/or infectious disease specialist) should be considered. ■ Evaluate patients for latent tuberculosis (TB). Patients testing positive in TB screening should be treated with a standard TB regimen before initiating belatacept therapy. ■ Monitor for S/S of infection; see Antidote. ■ Monitor renal function closely and consider PVAN if renal function is deteriorating. ■ New-onset diabetes, dyslipidemia, and hypertension may occur; monitor blood sugar, lipid panel, and BP. ■ Monitor for infusion reactions (primarily hypertension and hypotension). ■ See Precautions.

Patient Education:

Read manufacturer's patient information sheet before each infusion. ■ Risk of other malignancies, especially skin cancer, is increased. Report S/S of skin cancer, such as suspicious moles or lesions. Limit exposure to sunlight and UV light. Wear protective clothing and use a sunscreen with a high protection factor. ■ Promptly report confusion, thinking problems, and loss of memory; decreased strength or weakness on one side of the body; and changes in mood or behavior, walking or talking, and vision. ■ Promptly report S/S of infection (e.g., fever, malaise). Adherence to prescribed antimicrobial prophylaxis is imperative. ■ Information on use in pregnant women is not available. Pregnancy registry available to monitor maternal-fetal outcomes. ■ Live vaccines should be avoided.

Maternal/Child:

Insufficient data to inform on drug-associated risk in pregnant women. ■ There are no data on the presence of belatacept in human milk or on the effects on breast-fed infants or human milk production; consider risk versus benefit. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Safety and effectiveness similar to that seen in younger adults.

DRUG/LAB INTERACTIONS

A change of **mycophenolic acid (MPA)** exposure may occur with a crossover from **cyclosporine to belatacept** or from **belatacept to cyclosporine** in patients concomitantly receiving **MMF**. Cyclosporine decreases MPA exposure by preventing enterohepatic recirculation of MPA, whereas belatacept does not. A higher MMF dosage may be needed after switching from belatacept to cyclosporine because cyclosporine may cause lower MPA concentrations and increase the risk of graft rejection. A lower MMF dosage may be needed after switching from cyclosporine to belatacept because this switch may result in higher MPA concentrations and increase the risk for adverse reactions related to MPA. ■ If **anti-thymocyte globulin** (or any other cell-depleting immunosuppressive induction treatment) and belatacept will be administered concomitantly, a 12-hour interval between the two administrations is suggested to reduce the risk of venous thrombosis of the renal allograft. ■ Avoid the use of **live vaccines** during treatment with belatacept, including but not limited to intranasal influenza, measles, mumps, rubella, oral polio, BCG, yellow fever, varicella, and Ty21a typhoid vaccines.

SIDE EFFECTS

Anemia, constipation, cough, diarrhea, fever, graft dysfunction, headache, hyperkalemia, hypertension, hypokalemia, leukopenia, nausea, peripheral edema, urinary tract infection, and vomiting are most common. Posttransplant lymphoproliferative disorder (PTLD), predominantly CNS PTLD; other malignancies; and serious infections, including JC virus–associated progressive multifocal leukoencephalopathy (PML) and polyoma virus–associated nephropathy (PVAN), are the most serious potential side effects and may be life threatening. Abdominal pain, acne, anxiety, arthralgia, back pain, bronchitis, cytomegalovirus (CMV) and herpes infections, dizziness, dyslipidemia, dyspnea, dysuria, hematuria, hypercholesterolemia, hyperglycemia, hyperuricemia, hypocalcemia, hypomagnesemia, hypophosphatemia, hypotension, increased creatinine, influenza, infusion reactions, insomnia, nasopharyngitis, new-onset diabetes, proteinuria, renal tubular necrosis, tremor, tuberculosis, and upper respiratory infections may occur.

Post-Marketing:

Anaphylaxis and venous thrombosis of the renal allograft (with coadministration of anti-thymocyte globulin).

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. In case of overdose, it is recommended that the patient be monitored for any S/S of adverse reactions and appropriate symptomatic treatment instituted. If PML is confirmed or if patient develops evidence of PVAN, consider reducing or discontinuing immunosuppression, taking into account the risk to the allograft. Therapy may need to be interrupted in patients who develop infections. Treat infusion reactions as indicated. Resuscitate as necessary.

BELIMUMAB

(be-**LIM**-ue-mab)
Benlysta
Monoclonal antibody
pH 6.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Premedication:

Consider premedication (e.g., antihistamines, H_2 antagonists, and/or corticosteroids) to help prevent or minimize hypersensitivity/infusion reactions.

Belimumab:

10 mg/kg as an infusion at 2-week intervals for the first 3 doses. Administer at 4-week intervals thereafter.

DOSE ADJUSTMENTS

No dose adjustment is recommended for patients with renal or hepatic impairment.

DILUTION

Provided as a lyophilized powder in a single-dose vial for reconstitution and dilution before IV infusion. Available in two strengths (120 mg or 400 mg). Allow vial to reach RT before reconstitution (approximately 10 to 15 minutes). Using a 21- to 25-gauge needle, reconstitute the 120-mg vial with 1.5 mL SWFI and the 400-mg vial with 4.8 mL SWFI. Concentration for both will equal 80 mg/mL. Direct the SWFI toward the side of the vial to minimize foaming. Gently swirl for 60 seconds. Allow to sit at RT and gently swirl for 60 seconds every 5 minutes until completely dissolved. ***Do not shake.*** Reconstitution may take up to 30 minutes. If reconstituted with a mechanical swirler, do not exceed 500 rpm and/or a duration of 30 minutes. Protect from sunlight. Solution should be opalescent and colorless to pale yellow. Small air bubbles are expected and are acceptable.

Patients weighing more than 40 kg:

The desired dose of the reconstituted solution must be further diluted to 250 mL with NS, ½NS, or LR by withdrawing and discarding a volume equal to the desired dose from a 250-mL infusion bag or bottle of NS, ½NS, or LR.

Patients weighing less than or equal to 40 kg:

Withdraw and discard a volume equal to the desired dose from a 100-mL infusion bag or bottle of NS, ½NS or LR so that the resulting belimumab concentration in the infusion bag does not exceed 4 mg/mL. Add the desired dose of belimumab to the infusion bag or bottle and invert to mix the solution; see Storage.

Filters:

No data available from manufacturer.

Storage:

Before use, refrigerate vials (2° to 8° C [36° to 46° F]) in original carton, protected from light. Do not freeze. Avoid exposure to heat. Do not use beyond expiration date. Reconstituted solution, if not used immediately, should be refrigerated protected from direct sunlight. Solution diluted in NS, ½NS, or LR may be refrigerated or kept at RT. Total time from reconstitution to completion of the infusion should not exceed 8 hours. Discard any unused product.

COMPATIBILITY

Manufacturer states, "**Incompatible** with dextrose solutions," "No **incompatibilities** with polyvinylchloride or polyolefin bags observed," and "Should not be infused concomitantly in the same IV line with other agents."

RATE OF ADMINISTRATION

A single dose, properly diluted, as an infusion equally distributed over 1 hour. Slow or interrupt infusion rate if an infusion reaction develops. Do not administer as an IV push or bolus.

ACTIONS

A recombinant, DNA-derived, humanized monoclonal antibody. It is a B-lymphocyte stimulator (BLyS)–specific inhibitor that blocks the binding of soluble BLyS (a B-cell survival factor) to its receptors on B-cells. Does not bind with B-cells directly. However, by binding BLyS, it inhibits the survival of B-cells (including auto-reactive B-cells) and reduces the differentiation of B-cells into immunoglobulin-producing plasma cells. Significantly reduces circulating CD19+, CD20+, naïve, and activated B-cells, and the SLE B-cell subset. Reductions in IgG and anti–double-strand DNA antibodies and increases in complement (C3 and C4) were observed as early as Week 8 and sustained through Week 52. In pediatric dosing, the pharmacodynamic response was consistent with the adult data. Terminal half-life is 19.4 days.

INDICATIONS AND USES

As an IV infusion in the treatment of patients 5 years of age and older or as a subcutaneous injection in patients 18 years of age and older with active, autoantibody-positive, systemic lupus erythematosus (SLE) who are receiving standard therapy.

Limitations of use:

Efficacy has not been evaluated in patients with severe active lupus nephritis or severe active central nervous system lupus. Has not been studied in combination with other biologics or IV cyclophosphamide. Use of belimumab is not recommended in these situations.

CONTRAINDICATIONS

Patients who have experienced an anaphylactic hypersensitivity reaction with belimumab.

PRECAUTIONS

120-mg and 400-mg single-dose vials are for IV infusion only. Also available for SC injection in a prefilled autoinjector or a single-dose (200 mg/mL) prefilled glass syringe. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Serious hypersensitivity/infusion reactions, including anaphylaxis and death, have occurred. Acute hypersensitivity reactions usually occur within hours of the infusion. Nonacute reactions, including rash, nausea, fatigue, myalgia, headache, and facial edema, may occur up to a week following the infusion. Hypersensitivity, including serious reactions, has occurred in patients who have previously tolerated an infusion of belimumab. Patients with a history of multiple drug allergies or significant hypersensitivity may be at increased risk. Administration of premedications (which can mask or mitigate a reaction) and the overlap in S/S may make it difficult to distinguish between a hypersensitivity reaction and an infusion reaction. ■ Serious and sometimes fatal infections have been reported. Use with caution in patients with severe or chronic infections. ■ Cases of JC virus–associated progressive multifocal leukoencephalopathy (PML) resulting in neurologic deficits, including fatal cases, have been reported. Risk factors for PML include treatment with immunosuppressant therapies and impairment of immune function. ■ Psychiatric events, including depression, suicidal ideation and behavior, insomnia, and anxiety, have been reported. Most patients had a history of depression or other serious psychiatric disorders and were receiving psychoactive medications. ■ More deaths were reported with belimumab than with placebo during the controlled period of clinical trials. Etiologies included cardiovascular disease, infection, and suicide. No single cause of death predominated. ■ The impact of treatment with belimumab on the development of malignancies is not known. The mechanism of action of belimumab could increase the risk for the development of malignancies. ■ Anti-belimumab antibodies developed in a small percentage of patients. Clinical relevance is unknown. ■ Response rates were lower in Black/African-American patients; use with caution.

Monitor:

Obtain a baseline CBC, including a differential and platelet count. Monitor as indicated. ■ Monitor for hypersensitivity reactions carefully during and for an appropriate period of time after administration; delayed onset of severe hypersensitivity reactions has been reported. S/S reported include anaphylaxis, angioedema, dyspnea, hypotension, pruritus, rash, and urticaria. ■ On the day of the infusion, monitor for S/S of an infusion reaction (e.g., bradycardia, headache, hypotension, myalgia, nausea, rash, urticaria). ■ Monitor for S/S of PML, such as new-onset or deteriorating neurologic signs and symptoms. Consultation with a neurologist is recommended. ■ Consider interrupting therapy if a new infection develops during treatment with belimumab, and monitor patient closely. ■ Monitor for S/S of psychiatric events (e.g., depression, and suicidal ideation and behavior).

Patient Education:

Read FDA-approved medication guide. ■ Women of childbearing potential should use effective contraceptive methods during treatment and for a minimum of 4 months after the final treatment. ■ Manufacturer has established a pregnancy registry, and patients who are or who become pregnant are encouraged to register. ■ Tell your health care provider if you are allergic to any medications. ■ Promptly report anxiousness, difficulty breathing; dizziness or fainting; headache; itching; low blood pressure; nausea; skin rash, redness, or swelling; swelling of the face, lips, mouth, tongue, or throat; may indicate a hypersensitivity/infusion reaction. ■ Promptly report diarrhea, chest discomfort or pain, chills, cold sweats, coughing up mucus, dizziness, fever, nausea, new or worsening depression or suicidal thoughts, pain or burning with urination, unusual changes in behavior or mood, frequent urination, warm, red, or painful skin or sores on your body. ■ Promptly report new or worsening neurologic symptoms (e.g., confusion, difficulty talking or walking, dizziness, loss of balance, memory loss, or vision problems). ■ Do not receive live vaccines while taking belimumab.

Maternal/Child:

Monoclonal antibodies, including belimumab, are actively transported across the placenta during the third trimester of pregnancy and may affect immune response in infants exposed to belimumab in utero. However, there are risks to both the mother and the fetus associated with SLE. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Clinical data are lacking regarding safety during breast-feeding. Consider risk versus benefit. ■ Safety and effectiveness of IV administration has been established in pediatric patients 5 years of age and older. The safety and effectiveness for use in pediatric patients under 5 years of age has not been established. ■ Risks and benefits should be considered before administering live or live-attenuated vaccines to infants exposed to belimumab in utero. Monitor the infant of a treated mother for B-cell reduction and other immune dysfunction.

Elderly:

Numbers in clinical studies are insufficient to determine if the elderly respond differently than younger subjects; use with caution.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been performed. ■ Has not been studied in combination with other **biologics, including B-cell–targeted therapies or IV cyclophosphamide;** concurrent use is not recommended. ■ Do not administer **live virus vaccines** for 30 days before or concurrently with belimumab. ■ Risks and benefits should be considered before administering live or live-attenuated vaccines to infants exposed to belimumab in utero.

SIDE EFFECTS

Bronchitis, depression, diarrhea, fever, insomnia, migraine, nasopharyngitis, nausea, pain in extremities, and pharyngitis were most commonly reported. Cystitis, leukopenia, and viral gastroenteritis have also been reported. Serious side effects include depression and suicidality, hypersensitivity reactions (including anaphylaxis), infusion reactions, malignancy, serious infections, and death.

Post-Marketing:

Fatal anaphylaxis.

ANTIDOTE

Notify physician of all side effects. Treatment of most side effects will be supportive. Consider interrupting therapy if a new infection develops during treatment with belimumab. If PML is confirmed, consider discontinuing immunosuppressant therapy, including belimumab. Slow or interrupt infusion rate if an infusion reaction develops. Infusion reactions may be treated with acetaminophen, antiemetics, H_2 antagonists, or corticosteroids as indicated. Discontinue if a serious hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines.

BELINOSTAT

(be-**LIN**-oh-stat)
Beleodaq
Antineoplastic

USUAL DOSE

Pretreatment:

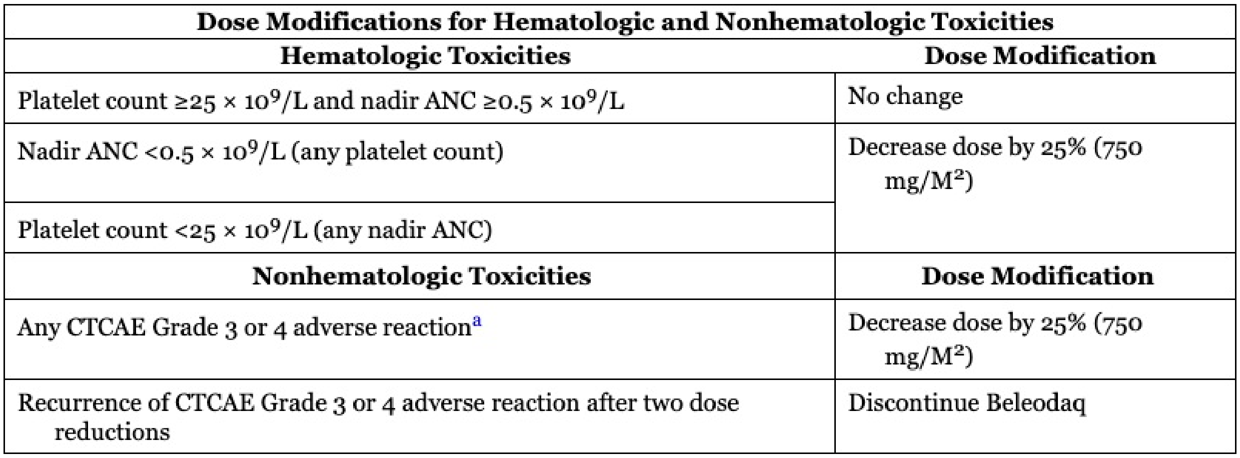
Verify pregnancy status. Baseline studies indicated; see Monitor.

Belinostat:

1,000 mg/M^2 administered over 30 minutes by IV infusion once each day on Days 1 through 5 of a 21-day cycle. Cycles can be repeated every 21 days until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Before the start of each cycle and before resuming treatment following toxicity, the absolute neutrophil count (ANC) should be greater than or equal to 1×10^9/L (1,000/mm^3), and the platelet count should be greater than or equal to 50×10^9/L (50,000/mm^3). ■ Other toxicities must be CTCAE Grade 2 or less before retreatment. ■ Reduce the starting dose of belinostat to 750 mg/M^2 in patients known to be homozygous for the UGTIA1*28 allele. ■ See the following chart for dose modifications for hematologic and nonhematologic toxicities. Base the dose adjustments for thrombocytopenia and neutropenia on platelet and absolute neutrophil nadir (lowest value) counts in the preceding cycle of therapy.



Dose Modifications for Hematologic and Nonhematologic Toxicities	
Hematologic Toxicities	**Dose Modification**
Platelet count $\geq 25 \times 10^9$/L and nadir ANC $\geq 0.5 \times 10^9$/L	No change
Nadir ANC $<0.5 \times 10^9$/L (any platelet count)	Decrease dose by 25% (750 mg/M^2)
Platelet count $<25 \times 10^9$/L (any nadir ANC)	
Nonhematologic Toxicities	**Dose Modification**
Any CTCAE Grade 3 or 4 adverse reaction[a]	Decrease dose by 25% (750 mg/M^2)
Recurrence of CTCAE Grade 3 or 4 adverse reaction after two dose reductions	Discontinue Beleodaq

[a] For nausea, vomiting, and diarrhea, dose modify only if the duration is greater than 7 days with supportive management.

■ Data insufficient to recommend dosing in patients with moderate to severe hepatic impairment (bilirubin greater than 1.5 times the ULN) or in patients with a CrCl 39 mL/min or less.

DILUTION

Specific techniques required; see Precautions. Available in single-use vials containing lyophilized powder equivalent to 500 mg belinostat. Reconstitute each vial with 9 mL of SWFI (concentration is 50 mg/mL). Swirl contents until no visible particles remain. Withdraw the required dose and transfer to an infusion bag containing 250 mL of NS. Do not use if cloudiness or particulates are observed.

Filters:

Use of an infusion set with a 0.22-micron in-line filter is required for administration.

Storage:

Store in original packaging at CRT until use. Reconstituted vials may be stored for up to 12 hours at 15° to 25° C (59° to 77° F). Fully diluted solution may be stored at 15° to 25° C (59° to 77° F) for up to 36 hours, including infusion time.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV infusion equally distributed over 30 minutes through an infusion set with a 0.22-micron in-line filter. Infusion time may be extended to 45 minutes for infusion site pain or other symptoms potentially attributable to the infusion.

ACTIONS

A histone deacetylase (HDAC) inhibitor. HDACs catalyze the removal of acetyl groups from the lysine residues of histones and some non-histone proteins. In vitro, belinostat caused the accumulation of acetylated histones and other proteins, inducing cell-cycle arrest and/or apoptosis of some transformed cells. It shows preferential cytotoxicity toward tumor cells compared with normal cells. Highly bound to protein. Primarily metabolized by UGT1A1. Also undergoes some metabolism by selected cytochrome P_{450} isoenzymes. Elimination half-life is 1.1 hours. Excreted primarily in urine and to a lesser extent in feces.

INDICATIONS AND USES

Treatment of patients with relapsed or refractory peripheral T-cell lymphoma. This indication is approved under accelerated approval based on tumor response rate and duration of response. An improvement in survival or disease-related symptoms has not been established. Continued approval may be contingent on verification and description of clinical benefit in confirmatory trials.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of a physician specialist with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Can cause thrombocytopenia, leukopenia (neutropenia and lymphopenia), and/or anemia. See Monitor and Dose Adjustments. ■ Serious and sometimes fatal infections, including pneumonia and sepsis, have occurred. Do not administer belinostat to patients with an active infection. Patients with a history of extensive or intensive chemotherapy may be at higher risk for life-threatening infections. ■ Can cause fatal hepatotoxicity and liver function test abnormalities. Interrupt or adjust dose until recovery, or permanently discontinue belinostat based on the severity of the hepatic toxicity; see Monitor and Dose Adjustments. ■ Tumor lysis syndrome (TLS) has occurred. May cause acute renal failure requiring dialysis and can be fatal. ■ Gastrointestinal toxicity has been reported. ■ Belinostat is metabolized in the liver. Use caution in patients with hepatic impairment. Patients with moderate and severe hepatic impairment (total bilirubin greater than 1.5 times the ULN) were excluded from clinical trials. ■ See Monitor.

Monitor:

Obtain baseline CBC, including platelets, and monitor weekly. ■ Obtain baseline serum chemistry tests, including renal and hepatic function, before the start of the first dose of each cycle. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for S/S of TLS; early signs are flank pain and hematuria. May progress to renal failure, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. Monitoring of serum electrolytes, uric acid, urine output, and renal function indicated. ■ Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol). ■ Monitor for thrombocytopenia (platelet count less than 50,000 mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Nausea, vomiting, and diarrhea may require the use of antiemetic and/or antidiarrheal medications. Use prophylactically to increase patient comfort.

Patient Education:

Review manufacturer’s patient information leaflet. ■ Avoid pregnancy. Effective birth control recommended for females of reproductive potential during treatment and for 6 months after the last dose and for males with female partners of reproductive potential during treatment and for 3 months after the last dose. ■ May impair male fertility. ■ Promptly report nausea, vomiting, and diarrhea; antiemetics and/or antidiarrheals may be indicated. ■ Promptly report symptoms of infection (e.g., fever). ■ Report bloody stools, bruising, fatigue. ■ Laboratory monitoring is imperative. ■ See Appendix D, p. 1311.

Maternal/Child:

Based on its mechanism of action and findings of genotoxicity, belinostat can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Patients 65 years of age and older had a higher response rate to belinostat than did younger adults. ■ No clinically meaningful differences in serious side effects were observed in patients based on age.

DRUG/LAB INTERACTIONS

Avoid concomitant administration of belinostat with **strong inhibitors of UGT1A1** (e.g., atazanavir). ■ Belinostat did not increase the AUC or C_{max} of **warfarin** (Coumadin). Dose adjustment of warfarin is not required when coadministered with belinostat. ■ Likely a glycoprotein (P-gp) substrate but not likely to inhibit P-gp.

SIDE EFFECTS

The most common side effects reported are anemia, fatigue, fever, nausea, and vomiting. Serious side effects reported include hematologic toxicity (anemia, lymphopenia, neutropenia, thrombocytopenia), hepatotoxicity and liver function abnormalities, increased SCr, infections (pneumonia, sepsis), multiorgan failure, and tumor lysis syndrome. Anemia, fatigue, febrile neutropenia, and multiorgan failure were reported as the reason for discontinuation of treatment. Other side effects reported include abdominal pain, chills, constipation, cough, decreased appetite, diarrhea, dizziness, dyspnea, headache, hypokalemia, hypotension, increased blood lactate dehydrogenase, infusion site pain, peripheral edema, phlebitis, prolonged QT, pruritus, and rash. Treatment-related deaths have occurred.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Supportive therapy as indicated will help sustain the patient in toxicity. Interrupt or adjust dose until recovery, or permanently discontinue belinostat based on the severity of the hematologic or hepatic toxicity. Hematologic toxicity may require dose adjustment. Neutropenia may be treated with filgrastim. Severe thrombocytopenia or anemia may require transfusion. Should a hypersensitivity reaction occur, treat as indicated.

BENDAMUSTINE HYDROCHLORIDE

(ben-deh-**MUS**-teen)
Bendeka, Treanda
Antineoplastic

Alkylating agent
pH 2.5 to 3.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

Premedication with antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen), and corticosteroids may be indicated; see Monitor and Antidote.

Chronic lymphocytic leukemia (CLL):

100 mg/M² as an IV infusion on Days 1 and 2 of a 28-day cycle. May be repeated for up to 6 cycles.

Non-Hodgkin lymphoma (NHL):

120 mg/M² as an IV infusion on Days 1 and 2 of a 21-day cycle. May be repeated for up to 8 cycles.

DOSE ADJUSTMENTS

Chronic lymphocytic leukemia (CLL) and non-Hodgkin lymphoma (NHL):

Delay treatment for Grade 4 hematologic toxicity or clinically significant nonhematologic toxicity equal to or greater than Grade 2. In addition, dose reduction may be indicated; see specific indication. Re-initiate treatment, if indicated, when nonhematologic toxicity has recovered to equal to or less than Grade 1 and/or the ANC has recovered to equal to or greater than 1,000 cells/mm³ and platelets have recovered to equal to or greater than 75,000 cells/mm³. ■ No dose adjustment indicated based on age or gender; see Precautions.

Chronic lymphocytic leukemia (CLL):

Reduce dose to 50 mg/M² on Days 1 and 2 of each cycle for Grade 3 or greater hematologic toxicity. If Grade 3 or greater toxicity recurs, reduce dose to 25 mg/M² on Days 1 and 2 of each cycle. ■ Reduce dose to 50 mg/M² on Days 1 and 2 of each cycle for clinically significant Grade 3 or greater nonhematologic toxicity. ■ Dose re-escalation in subsequent cycles may be considered by the treating physician.

Non-Hodgkin lymphoma (NHL):

Reduce dose to 90 mg/M² on Days 1 and 2 of each cycle for Grade 4 hematologic toxicity. If Grade 4 toxicity recurs, reduce the dose to 60 mg/M² on Days 1 and 2 of each cycle. ■ Reduce dose to 90 mg/M² on Days 1 and 2 of each cycle for Grade 3 or greater nonhematologic toxicity. If Grade 3 or greater toxicity recurs, reduce the dose to 60 mg/M² on Days 1 and 2 of each cycle.

DILUTION

Specific techniques required; see Precautions.

Treanda is available in **two formulations:** a solution **(Treanda Injection)** and a lyophilized powder **(Treanda for Injection)**. Formulations have different concentrations. **Do not mix or combine the two formulations.**

Treanda Injection is available as a solution in 45 mg/0.5 mL and 180 mg/2 mL single-use vials. **Do not use with devices containing polycarbonate or acrylonitrile-butadiene-styrene (ABS), including closed-system transfer devices (CSTDs), adapters, and syringes when preparing the infusion bag.** Must be diluted in a biosafety cabinet or a containment isolator. Aseptically withdraw the volume needed for the required dose and transfer to a 500-mL infusion bag of NS or D2.5/½NS using a polypropylene syringe with a metal needle and polypropylene hub. (Polypropylene syringes are translucent in appearance.) Final concentration of infusion solution should be 0.2 to 0.7 mg/mL. Mix thoroughly; solution should be clear and colorless to slightly yellow; see Compatibility. After dilution of **Treanda Injection** in the infusion bag, devices that contain ABS or polycarbonate, including infusion sets, may be used.

Treanda for Injection and **generic products** are available as a lyophilized powder in 25- and 100-mg single-use vials. **If a CSTD or adapter that contains polycarbonate or ABS is to be used as supplemental protection during preparation, use only this formulation (lyophilized powder for injection).** Reconstitute each 25-mg vial with 5 mL SWFI and each 100-mg vial with 20 mL SWFI; concentration is 5 mg/mL. Shake well. Should completely dissolve in 5 minutes. Within 30 minutes of reconstitution, withdraw the desired dose from the vial(s) and further dilute in 500 mL of NS or D2.5/½NS. Final concentration should be 0.2 to 0.6 mg/mL. Mix thoroughly; solution should be clear and colorless to slightly yellow.

Bendeka is available as a ready-to-dilute solution in 100 mg/4 mL multiple-dose vials. Withdraw the volume needed for the required dose and immediately transfer into a 50-mL infusion bag of NS, D5W, or D2.5/½NS. The final concentration should be 1.85 to 5.6 mg/mL. The final admixture should be a clear and colorless to yellow solution.

Filters:

Specific information not available.

Storage:

All formulations:

Retain in original package to protect from light. **Bendeka** must be stored in the refrigerator at 2° to 8° C (36° to 46° F) in original carton to protect from light. When refrigerated, the contents may partially freeze. Allow the vial to reach room temperature (RT) (15° to 30° C [59° to 86° F]) before use. If particulate matter is observed after achieving RT, the product should be discarded. Solution diluted in NS or D2.5/½NS is stable for 6 hours at RT and in room light or for 24 hours refrigerated. Solution diluted in D5W is stable for 3 hours at RT and in room light or for 24 hours refrigerated.

Administration must be completed within these times (e.g., 3, 6, or 24 hours based on type of storage and solution used). **Bendeka** is supplied as a multiple-dose vial that is stable for up to 28 days after initial vial entry when stored in its original carton under refrigeration. Manufacturer recommends no more than 6 dose withdrawals from each vial. **Treanda Injection** must be stored in the refrigerator. Solution diluted in NS or D2.5/½NS is stable for 2 hours at RT and in room light or for 24 hours refrigerated. Administration must be completed within these times (e.g., 2 or 24 hours based on type of storage). **Treanda for Injection and generic products** may be stored at CRT. Solution diluted in NS or D2.5/½NS is stable for 3 hours at RT and in room light or for 24 hours refrigerated. Administration must be completed within these times. Discard any unused solution.

COMPATIBILITY

Manufacturer states, "Use SWFI for reconstitution (for **Treanda for Injection**) and then (for **both formulations**) either NS or D2.5/½NS for dilution. No other diluents have been shown to be **compatible**."

Treanda Injection:

Contains N,N-dimethylacetamide (DMA), which is **incompatible** with devices that contain polycarbonate or ABS. Devices, including CSTDs, adapters, and syringes that contain polycarbonate or ABS, have been shown to dissolve when they come into contact with DMA. This **incompatibility** leads to device failure (e.g., leaking, breaking, or operational failure of CSTD components), possible product contamination, and potential serious adverse health consequences to the practitioner or patient.

RATE OF ADMINISTRATION

Bendeka:

All indications:

Total daily dose as an infusion equally distributed over 10 minutes.

Treanda and generic products:

Chronic lymphocytic leukemia (CLL):

Total daily dose as an infusion equally distributed over 30 minutes.

Non-Hodgkin lymphoma (NHL):

Total daily dose as an infusion equally distributed over 60 minutes.

ACTIONS

A bifunctional mechlorethamine derivative. An alkylating agent. Active against both quiescent and dividing cells. Exact mode of action unknown. May lead to cell death by damaging the DNA in cancer cells as well as by disrupting normal cell division. Highly protein bound. Distributes freely in human red blood cells. Extensively metabolized via hydrolytic, oxidative, and conjugative pathways. Half-life of the parent compound is approximately 40 minutes. Half-life of the two active metabolites, M3 and M4, are approximately 3 hours and 30 minutes, respectively. Excreted in urine and feces.

INDICATIONS AND USES

Treatment of patients with chronic lymphocytic leukemia (CLL). Study demonstrated a higher rate of overall response and a longer progression-free survival for bendamustine compared with chlorambucil (Leukeran). Effectiveness compared with first-line therapies other than chlorambucil has not been studied. ■ Treatment of patients with indolent B-cell non-Hodgkin lymphoma that has progressed during or within 6 months of treatment with rituximab (Rituxan) or a rituximab-containing regimen.

CONTRAINDICATIONS

Bendeka:

Known hypersensitivity to bendamustine, polyethylene glycol 400, propylene glycol, or monothioglycerol.

Treanda:

Known hypersensitivity to bendamustine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Do not use in patients with a CrCl less than 40 mL/min (Bendeka) or less than 30 mL/min (Treanda). Use with caution in patients with mild or moderate renal impairment; no formal studies conducted. ■ Use with caution in patients with mild hepatic impairment. Do not use in patients with moderate hepatic impairment (AST or ALT 2.5 to 10 times the ULN and total bilirubin 1.5 to 3 times the ULN) or severe hepatic impairment (total bilirubin greater than 3 times the ULN). No formal studies conducted. ■ Myelosuppression may be severe and require dose delays and/or subsequent dose reductions. Deaths from myelosuppression-related adverse reactions have occurred; see Dose Adjustments. ■ Infections, including hepatitis, pneumonia, and sepsis, have been reported. Has been associated with septic shock and death. ■ Patients treated with bendamustine are at risk for reactivation of infections, including (but not limited to) hepatitis B, cytomegalovirus, *Mycobacterium tuberculosis,* and herpes zoster; see Monitor. ■ Infusion reactions are common. In rare instances anaphylaxis or anaphylactoid reactions have occurred. Usually occur in the second and/or subsequent cycles of therapy. ■ Tumor lysis syndrome (TLS) has been reported and may occur in the first treatment cycle. S/S are renal insufficiency, hyperkalemia, hypocalcemia, hyperuricemia, or hyperphosphatemia. May lead to acute renal failure and death. ■ Fatal and serious skin reactions, including toxic skin reactions (Stevens-Johnson syndrome [SJS], toxic epidermal necrolysis [TEN], and drug reaction with eosinophilia and systemic syndrome [DRESS]), rash, and bullous exanthema, have been reported.

Reactions have occurred when bendamustine was given as a single agent and in combination with other anticancer agents or allopurinol; see Drug/Lab Interactions and Antidote. ■ Fatal and serious cases of liver injury have been reported. Combination therapy, progressive disease, or reactivation of hepatitis B were confounding factors in some patients. Most cases were reported within the first 3 months of therapy. ■ Premalignant and malignant diseases, including myelodysplastic syndrome, myeloproliferative disorders, acute myeloid leukemia, and bronchial carcinoma have been reported. Causal relationship has not been determined.

Monitor:

Patients should undergo appropriate measures (including clinical and laboratory monitoring, prophylaxis, and treatment) for infection and/or infection reactivation before treatment. ■ Obtain baseline CBC with differential and platelet count. Monitor CBC with differential weekly, and monitor platelet count each cycle. Hematologic nadir usually occurs in the third week. If recovery to recommended values does not occur by the first day of the next scheduled cycle, delay dose until recovery occurs; see Dose Adjustments. ■ Obtain baseline CrCl, AST, ALT, and total bilirubin; repeat as indicated. ■ Monitor closely for S/S of infusion or hypersensitivity reactions (e.g., chills, fever, pruritus, rash). Discontinue bendamustine if a severe reaction occurs. Inquire about possible symptoms that suggest a minor reaction after the first infusion. Consider premedication with antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen), and corticosteroids in patients who have experienced a Grade 1 or 2 infusion reaction; see Antidote. ■ Monitor for S/S of TLS. In patients at risk for TLS, prevention and treatment of hyperuricemia may be accomplished with vigorous hydration. Allopurinol has been used during the beginning of bendamustine therapy. However, there may be an increased risk of severe skin toxicity with concomitant use of allopurinol and bendamustine; see Drug/Lab Interactions. Monitor uric acid levels. Monitor electrolytes, particularly potassium, and treat as indicated. ■ Monitor patients with skin reactions closely. Withhold or discontinue bendamustine if skin reactions are severe or progressive. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Observe for S/S of infection (e.g., fever) or reactivation of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000 cells/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor IV site for signs of extravasation during and after administration (e.g., infection, pain, redness, swelling, necrosis); extravasation has resulted in hospitalization.

Patient Education:

Avoid pregnancy; effective birth control is recommended for both men and women throughout treatment and for 3 months (for men) and 6 months (for women) after treatment is complete; report a suspected pregnancy immediately. ■ May pose a risk to reproductive capacity in both males and females. May cause impaired spermatogenesis, azoospermia, and total germinal aplasia in males. ■ Promptly report signs of infection (e.g., chills, fever) or allergic reaction (e.g., dyspnea, itching, rash) and severe or worsening skin reactions, including itching or rash. ■ Promptly report signs of liver toxicity (e.g., anorexia, bleeding or bruising, jaundice). ■ Frequent laboratory monitoring required. ■ Promptly report IV site burning or stinging. ■ Report other side effects such as nausea, vomiting, or diarrhea. Symptomatic treatment can be provided. ■ May cause fatigue. Avoid driving or operating any dangerous tools or machinery if this side effect is experienced. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy; can cause fetal harm. Males and females of childbearing age must use effective birth control. ■ If the drug is used during pregnancy or if the patient becomes pregnant during therapy, inform the patient of the potential hazard to the fetus. ■ Has the potential for serious side effects; breast-feeding is not recommended during treatment and for at least 1 week after the last dose. ■ Effectiveness for use in pediatric patients not established. Evaluation of one small Phase 1/2 trial suggests that the safety profile in pediatric patients is similar to that seen in adults; see prescribing information.

Elderly:

Side effect profile similar for all age-groups studied. Patients over age 65 years with CLL had a lower overall response rate and a shorter progression-free survival than CLL patients under age 65. In NHL patients, efficacy (overall response rate and duration of response) was similar for all age-groups.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been conducted. ■ Active metabolites of bendamustine are formed via cytochrome P_{450} CYP1A2. **Inhibitors of CYP1A2** (e.g., ciprofloxacin, fluvoxamine) may increase plasma concentrations of bendamustine and decrease plasma concentrations of active metabolites. **Inducers of CYP1A2** (e.g., omeprazole, smoking) may decrease plasma concentrations of bendamustine and increase plasma concentrations of its active metabolites. Use caution or consider alternative treatments if concomitant treatment with CYP1A2 inhibitors or inducers is indicated. ■ Not likely to inhibit metabolism via other selected CYP isoenzymes or to induce the metabolism of substrates of cytochrome P_{450} enzymes. ■ Incidence of severe skin reactions (e.g., SJS, TEN, and DRESS) may be increased when bendamustine is given concomitantly with **allopurinol and other medications known to cause these syndromes** (e.g., rituximab). ■ In vitro data suggest that P-glycoprotein, breast cancer resistance protein (BCRP), and/or other efflux transporters may have a role in bendamustine transport.

SIDE EFFECTS

Anorexia, constipation, cough, diarrhea, dyspnea, fatigue, fever, headache, myelosuppression (anemia, febrile neutropenia, leukopenia, lymphopenia, neutropenia, thrombocytopenia), nausea, rash, stomatitis, vomiting, and weight loss were most common. Other side effects reported include abdominal pain; anxiety; arthralgia; asthenia; back pain; bone pain; chest pain; chills; decreased CrCl; dehydration; depression; dizziness; dry mouth; dry skin; dysgeusia; dyspepsia; elevated AST, ALT, and bilirubin levels; gastroesophageal reflux disease; herpes simplex and herpes zoster; hypersensitivity and/or infusion reactions (e.g., anaphylaxis [rare], pruritus, rash); hypertension; hyperuricemia; hypokalemia; infections; infusion site reactions; insomnia; malignancies; nasal congestion; nasopharyngitis; night sweats; oral candidiasis; pain; peripheral edema; pharyngolaryngeal pain; pneumonia; sepsis; stomatitis; tachycardia; TLS; and wheezing. Hypersensitivity reactions and fever required study withdrawal in some patients.

Post-Marketing:

Anaphylaxis, cardiac disorders (atrial fibrillation, CHF [some fatal], MI [some fatal], palpitation), DRESS, extravasation resulting in hospitalization, infusion site reactions (irritation, pain, phlebitis, pruritus, swelling), pancytopenia, *Pneumocystis jiroveci* pneumonia, pneumonitis, Stevens-Johnson syndrome, and toxic epidermal necrolysis.

Overdose:

Ataxia, cardiac arrhythmias, convulsions, respiratory distress, sedation, tremor.

ANTIDOTE

Keep physician informed of all side effects and hematologic parameters. Side effects may decrease in severity with reduced dose. Bone marrow depression may require withholding bendamustine until recovery occurs. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Selected blood modifiers (e.g., erythropoiesis-stimulating agents, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Discontinue the infusion immediately for any life-threatening side effect (e.g., clinically significant bronchospasm, cardiac arrhythmias, severe hypotension). Consider premedication with antihistamines (e.g., diphenhydramine), antipyretics (e.g., acetaminophen), and corticosteroids in subsequent cycles in patients who have experienced a Grade 1 or 2 hypersensitivity and/or infusion reaction. Grade 3 or 4 reactions have not typically been rechallenged; consider discontinuing bendamustine. Withhold or discontinue bendamustine if skin reactions are severe or progressive. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. ECG monitoring may be indicated to evaluate cardiac side effects.

BENZTROPINE MESYLATE

(**BENS**-troh-peen **MES**-sih-layt)
Cogentin
Antidyskinetic
Antiparkinson
Anticholinergic
pH 5 to 8

USUAL DOSE

Individualized based on age, weight, and type of parkinsonism. One dose daily, usually at bedtime, provides relief for most patients; however, divided doses (two or four times daily) may be beneficial in selected patients. Has a cumulative action. Initiate treatment with lower doses. Increase in increments of 0.5 mg at 5- to 6-day intervals until optimal results are obtained without excessive side effects or a maximum dose of 6 mg is reached.

Idiopathic parkinsonism:

0.5 to 1 mg/day at bedtime. Up to 4 to 6 mg/day may be required.

Postencephalitic parkinsonism:

2 mg/day. May be given in 1 or more doses. In highly sensitive patients, begin with a 0.5-mg dose at bedtime and increase as indicated.

Drug-induced extrapyramidal disorders:

1 to 4 mg given once or twice daily. Most effective with extrapyramidal disorders that develop soon after beginning treatment with neuroleptic agents (e.g., phenothiazines, haloperidol). Withhold after 1 to 2 weeks. If still needed, may be restarted. Drug-induced extrapyramidal disorders that develop slowly may not respond to benztropine.

Acute dystonic reactions:

1 to 2 mg usually provides quick relief.

PEDIATRIC DOSE

Has atropine-like side effects but may be used with caution in pediatric patients over 3 years of age. See Usual Dose and begin at low end of dosing range. See Contraindications.

DOSE ADJUSTMENTS

Begin with the lower end of the dosing range and increase gradually, especially in thin or elderly patients. In the elderly, consider potential for age-related impaired organ function and concomitant disease or drug therapy. ■ Reduced doses may be indicated if weakness and/or inability to move a particular muscle group occurs (may be more frequent with larger doses). ■ Reduced doses may be indicated during hot weather, especially with concomitant use of other atropine-like drugs; in patients with alcoholism, CNS disease, or other chronic illnesses; and in patients who do manual labor in a hot environment. ■ Reduce dose or temporarily discontinue for severe dry mouth that results in difficulty swallowing or speaking or for loss of appetite and weight.

DILUTION

1 mL of prepared solution equals 1 mg. May be given undiluted.

Storage:

Store at CRT. Do not freeze.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose equally distributed over 1 minute.

ACTIONS

Has both anticholinergic and antihistaminic effects. Onset of action occurs within minutes by IV or IM route. Undergoes hepatic metabolism.

INDICATIONS AND USES

Adjunct in therapy of all forms of parkinsonism. ■ Control of extrapyramidal disorders (except tardive dyskinesia) due to neuroleptic drugs (e.g., haloperidol, phenothiazines [e.g., chlorpromazine, prochlorperazine]).

CONTRAINDICATIONS

Pediatric patients under 3 years of age. ■ Known hypersensitivity to benztropine or its components.

PRECAUTIONS

IV route seldom used except in acute drug reactions or psychotic episodes. ■ Use caution in patients with tachycardia and/or prostatic hypertrophy; monitor closely. ■ Use with caution in patients with glaucoma. May be used in patients with simple glaucoma; however, benztropine is not recommended for use in patients with angle-closure glaucoma. ■ Mental and/or physical abilities required for performance of hazardous tasks may be impaired. ■ Concomitant use with phenothiazines and/or tricyclic antidepressants may cause fever, GI upset, heat intolerance, heat stroke, hyperthermia, and paralytic ileus. Fatalities have occurred. ■ May produce anhidrosis (deficient or absent sweating). ■ May aggravate the symptoms of tardive dyskinesia; see Contraindications. ■ May intensify symptoms (e.g., mental confusion and excitement, visual hallucinations) and may precipitate a toxic psychosis in patients with mental disorders, especially with larger doses.

Monitor:

Has a cumulative action; close observation is required. ■ Monitor for S/S of paralytic ileus (e.g., abdominal pain, constipation, distention), especially in patients receiving other anticholinergic or neuroleptic agents. ■ May cause dysuria and/or urinary retention; monitor urine output. ■ Observe for weakness and inability to move particular muscle groups; see Dose Adjustments. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Promptly report abdominal pain or distention, constipation, fever, GI upset, heat intolerance, inability to sweat, and pain or difficulty urinating. ■ Ability to perform hazardous tasks may be impaired.

Maternal/Child:

Safety for use during pregnancy and breast-feeding not established. ■ May inhibit lactation. ■ Has atropine-like effects; do not use in pediatric patients under 3 years of age, and use caution in pediatric patients over 3 years of age. See Pediatric Dose and Contraindications.

Elderly:

See Dose Adjustments and Precautions. ■ May produce agitation, confusion, disorientation, hallucinations, or psychotic-like symptoms. ■ Has the potential to increase memory impairment. ■ Chronic use may precipitate glaucoma.

DRUG/LAB INTERACTIONS

Concomitant use with **phenothiazines and/or tricyclic antidepressants** may cause fever, GI upset, heat intolerance, heat stroke, hyperthermia, and paralytic ileus. ■ Use with **other anticholinergic agents** may increase the risk of adverse anticholinergic effects (e.g., blurred vision, delirium, dry mouth, hyperpyrexia). ■ May reduce effectiveness of **neuroleptic drugs** (e.g., haloperidol) and increase the risk of adverse anticholinergic effects. Use with haloperidol may worsen schizophrenic symptoms and may precipitate tardive dyskinesia. ■ May reduce the effectiveness of levodopa by reducing the amount of levodopa absorbed in the GI tract. Monitor pharmacologic response to levodopa closely with concomitant use.

SIDE EFFECTS

Blurred vision, constipation, depression, dilated pupils, dry mouth, dysuria, exacerbation of pre-existing psychotic symptoms, fever, heat stroke, hypersensitivity reaction (e.g., skin rash), hyperthermia, listlessness, nausea, nervousness, numbness of fingers, paralytic ileus, tachycardia, toxic psychosis (e.g., confusion, disorientation, memory impairment, visual hallucinations), urinary retention, vomiting.

Overdose:

In addition to the above side effects, anhidrosis; ataxia; CNS depression; coma; convulsions; delirium; dizziness; dysphagia; glaucoma; headache; hot, dry, flushed skin; hypertension; muscle weakness; mydriasis; palpitations; respiratory arrest; and shock may occur.

ANTIDOTE

Notify the physician of all side effects. If a hypersensitivity reaction (e.g., skin rash) is not controlled by dose reduction, discontinue benztropine. Treat overdose with physostigmine salicylate 1 to 2 mg SC or IV to reverse symptoms of anticholinergic intoxication. May be repeated in 2 hours if indicated. Observe for relapses up to 12 hours. Treat symptoms of overdose symptomatically. Respiratory support, diazepam for CNS excitement (use with caution to avoid subsequent depression), local miotics (e.g., pilocarpine ophthalmic) for mydriasis (pupil dilation) or cycloplegia (paralysis of the ciliary muscle of the eye), cold applications (e.g., ice bags, alcohol sponges) for hyperpyrexia, a vasopressor (e.g., dopamine) and IV fluids for circulatory collapse, and darkening of the room for photophobia may all be indicated. Resuscitate as necessary.

BEVACIZUMAB ▪ BEVACIZUMAB-awwb[a] ▪ BEVACIZUMAB-bvzr[a]

(beh-vah-**SIZZ**-ih-mab)

Avastin, Mvasi[a], Zirabev[a], Vegzemla
Recombinant monoclonal antibody
Vascular Endothelial Growth Factor (VEGF) Inhibitor
Antineoplastic
pH 6.2

USUAL DOSE

Bevacizumab-awwb (Mvasi)[a], and bevacizumab-bvzr (Zirabev)[a] and bevacizumab-adcd (Vegzemla) are biosimilar drugs of bevacizumab (Avastin). Unless specifically stated otherwise, the use of the name *bevacizumab* or *bevacizumab products* applies to all formulations.

Pretreatment:

Do not begin therapy until at least 28 days following surgery and the wound is fully healed. Verify pregnancy status. Baseline studies indicated; see Monitor.

Bevacizumab products

May be used in combination with other antineoplastic agents or as a single agent. See Dose Adjustments, Monitor, and Precautions.

Metastatic colorectal cancer (mCRC):

Recommended doses are either 5 mg/kg or 10 mg/kg IV every 2 weeks when used in combination with intravenous 5-FU–based chemotherapy. Administer 5 mg/kg IV every 2 weeks when used in combination with bolus IFL (irinotecan, fluorouracil, leucovorin calcium). Administer 10 mg/kg IV every 2 weeks when used in combination with FOLFOX4 (fluorouracil, leucovorin calcium, and oxaliplatin).

Administer 5 mg/kg IV every 2 weeks or 7.5 mg/kg IV every 3 weeks when used in combination with a fluoropyrimidine-irinotecan–based or a fluoropyrimidine-oxaliplatin–based chemotherapy in patients who have progressed on a first-line bevacizumab-containing regimen.

First-line non-squamous, non–small-cell lung cancer (NSCLC):

15 mg/kg IV every 3 weeks in combination with carboplatin and paclitaxel.

Recurrent glioblastoma:

10 mg/kg IV every 2 weeks.

Metastatic renal cell carcinoma (mRCC):

10 mg/kg IV every 2 weeks in combination with interferon alfa.

Persistent, recurrent, or metastatic cervical cancer:

15 mg/kg IV every 3 weeks administered in combination with paclitaxel and cisplatin, or in combination with paclitaxel and topotecan.

Bevacizumab (Avastin)

Stage III or IV epithelial ovarian, fallopian tube, or primary peritoneal cancer after initial surgical resection:

15 mg/kg IV every 3 weeks in combination with carboplatin and paclitaxel for up to 6 cycles, followed by bevacizumab 15 mg/kg IV every 3 weeks as a single agent for a total of up to 22 cycles or until disease progression, whichever occurs earlier.

Platinum-resistant recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer:

10 mg/kg IV every 2 weeks in combination with paclitaxel, pegylated liposomal doxorubicin, or topotecan (weekly); or 15 mg/kg IV every 3 weeks in combination with topotecan (every 3 weeks).

Platinum-sensitive recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer:

15 mg/kg IV every 3 weeks when administered in combination with carboplatin and paclitaxel for 6 to 8 cycles, followed by bevacizumab 15 mg/kg IV every 3 weeks as a single agent until disease progression. Alternatively, 15 mg/kg IV every 3 weeks when administered in combination with carboplatin and gemcitabine for 6 to 10 cycles, followed by bevacizumab 15 mg/kg IV every 3 weeks as a single agent until disease progression.

DOSE ADJUSTMENTS

No dose reduction for bevacizumab products is recommended. ■ Modify doses for adverse reactions based on the following chart.

Dose Modifications for Adverse Reactions

Adverse Reaction	Severity	Dose Modification
Gastrointestinal perforation and fistulae	• Gastrointestinal perforation, any grade • Tracheoesophageal fistula, any grade • Fistula, Grade 4 • Fistula formation involving any internal organ	Discontinue bevacizumab
Wound healing complications	• Wound healing complications requiring medical intervention • Necrotizing fasciitis	Discontinue bevacizumab
Hemorrhage	• Grade 3 or 4	Discontinue bevacizumab
	• Recent history of hemoptysis of ½ teaspoon (2.5 mL) or more	Withhold bevacizumab
Thromboembolic events	• Arterial thromboembolism, severe	Discontinue bevacizumab
	• Venous thromboembolism, Grade 4	Discontinue bevacizumab
Hypertension	• Hypertensive crisis • Hypertensive encephalopathy	Discontinue bevacizumab
	• Hypertension, severe	Withhold bevacizumab if not controlled with medical management; resume once controlled
Posterior reversible encephalopathy syndrome (PRES)	• Any	Discontinue bevacizumab
Renal injury and proteinuria	• Nephrotic syndrome	Discontinue bevacizumab
	• Proteinuria greater than or equal to 2 Gm/24 hr in absence of nephrotic syndrome	Withhold bevacizumab until proteinuria less than 2 grams/24 hr
Infusion reaction	• Severe infusion reaction	Discontinue bevacizumab
	• Clinically significant	Interrupt infusion; resume at a decreased rate of infusion after symptoms resolve
	• Mild, clinically insignificant	Decrease infusion rate
Congestive heart failure	• Any	Discontinue bevacizumab

- See Monitor and Precautions.

DILUTION

Available in single-use vials containing 100 mg in 4 mL or 400 mg in 16 mL (25 mg/mL). ***Avastin and Zirabev*** are clear to slightly opalescent and colorless to pale brown. ***Mvasi*** is clear to slightly opalescent and colorless to pale yellow. Calculate desired dose and choose the appropriate vial or combination of vials. Withdraw the required volume of the bevacizumab product and dilute in a total volume of 100 mL of NS.

Filters:

Not required by manufacturer; however, studies with ***Avastin*** using a 0.2-micron in-line filter were done, and drug potency appeared to be maintained.

Storage:

Store in original carton in refrigerator at 2° to 8° C (36° to 46° F) until time of use. Protect from light. ***Do not shake or freeze.*** Diluted solutions may be refrigerated for up to 8 hours. Contains no preservatives; unused portions must be discarded.

COMPATIBILITY

Manufacturer states, “Do not administer or mix with dextrose solutions.” **Incompatibilities** with polyvinylchloride or polyolefin bags have not been observed with ***Avastin***.

RATE OF ADMINISTRATION

Must be given as an IV infusion.

Initial infusion:

A single dose equally distributed over 90 minutes.

Second infusion:

If the initial infusion is well tolerated, the second infusion may be administered equally distributed over 60 minutes.

Subsequent infusions:

If the 60-minute infusion is well tolerated, subsequent infusions may be administered equally distributed over 30 minutes.

ACTIONS

A humanized IgG_1 monoclonal antibody produced by recombinant DNA technology. Has antiangiogenesis properties. The interaction of human vascular endothelial growth factor (VEGF) with its receptors leads to endothelial cell proliferation and new blood vessel formation. By binding VEGF, bevacizumab prevents the interaction of VEGF with its receptors on the surface of endothelial cells, thus inhibiting the development of new blood vessels around tumors (a tumor-starving mechanism) and resulting in a reduction of microvascular growth and an inhibition of metastatic disease progression. Predicted time to steady-state was 84 days. Half-life is approximately 20 days (range is 11 to 50 days). IgG antibodies may cross the placental barrier and be secreted in breast milk.

INDICATIONS AND USES

Bevacizumab products

First- or second-line treatment of metastatic colorectal cancer. Used in combination with intravenous 5-fluorouracil–based chemotherapy (e.g., IFL, FOLFOX4). ■ Second-line treatment of metastatic colorectal cancer in patients who have progressed on a first-line bevacizumab-containing regimen. Used in combination with fluoropyrimidine-irinotecan–based or fluoropyrimidine-oxaliplatin–based chemotherapy. ■ First-line treatment of patients with unresectable, locally advanced, recurrent, or metastatic nonsquamous, non–small-cell lung cancer. Given in combination with carboplatin and paclitaxel. ■ Treatment of recurrent glioblastoma in adults. ■ Treatment of metastatic renal cell cancer. Given in combination with interferon alfa. ■ Treatment of persistent, recurrent, or metastatic cervical cancer. Given in combination with paclitaxel and cisplatin or paclitaxel and topotecan.

Bevacizumab (Avastin)

Treatment of patients with platinum-resistant recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer who received no more than 2 prior chemotherapy regimens. Given in combination with paclitaxel, pegylated liposomal doxorubicin, or topotecan. ■ Treatment of patients with platinum-sensitive recurrent epithelial ovarian, fallopian tube, or primary peritoneal cancer. Given in combination with carboplatin and paclitaxel or with carboplatin and gemcitabine, followed by bevacizumab as a single agent. ■ Treatment of patients with Stage III or IV epithelial ovarian, fallopian tube, or primary peritoneal cancer following initial surgical resection. Given in combination with carboplatin and paclitaxel, followed by bevacizumab as a single agent.

Limitation of use:

Bevacizumab products are not indicated for adjuvant treatment of colon cancer.

CONTRAINDICATIONS

Manufacturer states, “No known contraindications”; see Precautions and Antidote. ■ Avoid use in patients with ovarian cancer who have evidence of rectosigmoid involvement by pelvic examination or bowel involvement on CT scan or clinical symptoms of bowel obstruction.

PRECAUTIONS

Must be given as an infusion. ■ Should be administered by or under the direction of a physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Incidence of wound healing and surgical complications, including serious and fatal complications, is increased in patients receiving bevacizumab. Withhold bevacizumab for a minimum of 28 days after major surgery; surgical incision must be fully healed. Withhold at least 28 days before elective surgery (half-life is approximately 20 days but has a wide range). ■ GI perforation with or without fistula formation and/or intra-abdominal abscesses has occurred; deaths have been reported. The majority of cases occurred within the first 50 days of initiation of bevacizumab. Consider GI perforation in any patient with complaints of abdominal pain associated with constipation, fever, nausea, and vomiting. ■ Nongastrointestinal fistula formation has been reported, in some cases with a fatal outcome. Serious fistula formations involving tracheoesophageal, bronchopleural, biliary, vaginal, renal, and bladder areas have been reported. Most events occurred within the first 6 months of bevacizumab therapy. ■ Necrotizing fasciitis (including fatal cases) has been reported, usually secondary to wound healing complications, gastrointestinal perforation, or fistula formation. ■ Severe or fatal hemorrhage, including CNS hemorrhage, epistaxis, GI bleed, hematemesis, hemoptysis, and vaginal bleeding, occurred up to five times more frequently in patients receiving bevacizumab compared with patients receiving chemotherapy alone. Do not administer bevacizumab to patients with serious bleeding or a recent history of hemoptysis of ½ teaspoon or more of red blood. ■ May cause severe hypertension that may be persistent. Treatment is required; see Monitor and Antidote. ■ Posterior reversible encephalopathy syndrome (PRES) has been reported. Onset of symptoms occurred from 16 hours to 1 year after initiation of therapy. May present with blindness and other visual and neurologic disturbances, confusion, headache, lethargy, and seizures. Mild to severe hypertension may be present. MRI is required to confirm diagnosis. Symptoms usually resolve gradually with discontinuation of bevacizumab and treatment of hypertension. ■ Proteinuria occurred during studies and progressed to nephrotic syndrome in some patients. Findings consistent with thrombotic microangiopathy have been found on kidney biopsy in some patients. In some but not all patients, proteinuria decreased within several months after therapy was discontinued. Increased serum creatinine levels have occurred and may not return to baseline. ■ CHF has been reported. Incidence is higher in patients receiving chemotherapy plus bevacizumab compared with patients receiving chemotherapy alone. ■ Infusion reactions are infrequent but have occurred. ■ Serious and sometimes fatal arterial thromboembolic events (ATEs) (e.g., CVA [stroke], MI, TIA, angina) have been reported. The risk of developing an ATE was increased in patients with a history of arterial thromboembolism or diabetes and in patients greater than 65 years of age. ■ Venous thromboembolic events (e.g., deep vein thrombosis, intra-abdominal thrombosis, and pulmonary embolism) have been reported. ■ Increases the risk of ovarian failure in premenopausal women receiving bevacizumab (Avastin) with chemotherapy for adjuvant treatment of a solid tumor. Recovery of ovarian function is defined as resumption of menses, a positive serum β-HCG pregnancy test, or an FSH level less than 30 mIU/mL. Recovery of ovarian function occurred in some but not all women following discontinuation of therapy. Long-term effects of bevacizumab on fertility are unknown. ■ A protein substance, it has the potential for producing an immune response. Neutralizing antibodies against bevacizumab have been found using a specific immunosorbent assay; clinical significance is not known. ■ See Drug/Lab Interactions, Maternal/Child, and Antidote.

Monitor:

Obtain baseline BP, CBC with differential and platelets, and urinalysis. ■ Monitor for S/S of an infusion reaction (e.g., chest pain, chills, diaphoresis, headache, hypertension, hypertensive crisis associated with neurologic S/S, oxygen desaturation, rigors, wheezing). ■ Monitor BP at least every 2 to 3 weeks; monitor more frequently in patients with hypertension. Treat hypertension with appropriate antihypertensive therapy. Continue to monitor BP at regular intervals after bevacizumab therapy is discontinued. ■ Repeat CBC with differential and platelets as indicated. ■ Monitor for the development or worsening of proteinuria by serial dipstick urinalysis. Patients with a 2+ or greater urine dipstick reading should undergo further assessment with a 24-hour urine collection. Monitor patients with moderate to severe proteinuria until improvement and/or resolution is observed. Repeat urinalyses and/or 24-hour urine collections as indicated. ■ Monitor for S/S of CHF (e.g., cyanosis, dyspnea on exertion, edema, fatigue on exertion, hypoxemia, jugular venous distension, orthopnea, pulmonary rales, tachycardia, third heart sound). ■ Check surgical wounds for wound dehiscence. ■ Monitor for S/S of any type of bleeding. ■ Monitor for GI perforation or fistula formulation (e.g., abdominal pain, constipation, fever, hypotension, nausea and vomiting). ■ Monitor for S/S of thromboembolic events. ■ Monitor for S/S of PRES. Obtain MRI to confirm diagnosis if indicated. ■ See Dose Adjustments (Dose Modifications for Adverse Reactions), Rate of Administration, Precautions, and Antidote.

Patient Education:

May cause fetal harm; avoid pregnancy. Females of reproductive potential should use effective contraception during treatment with and for 6 months after the last dose of bevacizumab; see Maternal/Child. Women should report a suspected pregnancy immediately. ■ Increases risk of ovarian failure and may impair fertility. ■ Full disclosure of health history is imperative. ■ Promptly report any S/S of CHF. ■ Promptly report any S/S of an infusion reaction. ■ Promptly report any unusual or unexpected symptoms or side effects (e.g., abdominal pain, bleeding from any source, constipation, dyspnea, fever, persistent cough, rigors, sudden onset of worsening neurologic function, vomiting, wound separation). ■ Increased risk of arterial and venous thromboembolic events and wound healing complications. ■ Routine monitoring of BP and renal function required. ■ See Appendix D, p. 1311.

Maternal/Child:

May cause fetal harm based on findings from animal studies and the drug's mechanism of action. Animal models link angiogenesis and VEFG and VEFG Receptor 2 to critical aspects of female reproduction, embryofetal development, and postnatal development. ■ Discontinue breast-feeding during treatment with bevacizumab and for 6 months after the final dose. ■ Safety and effectiveness for use in pediatric patients not established. Nonmandibular osteonecrosis has been reported in pediatric patients under 18 years of age who have received bevacizumab. Bevacizumab is not approved for this patient population.

Elderly:

Overall survival was similar compared to younger adults; however, the incidence of some side effects was increased (e.g., arterial thromboembolic events).

DRUG/LAB INTERACTIONS

Drug interaction studies have not been completed. ■ Has been administered with

carboplatin, paclitaxel, and interferon alfa. May decrease paclitaxel exposure. ■ Several cases of microangiopathic hemolytic anemia (MAHA) have been reported in patients with solid tumors who are receiving concomitant therapy with bevacizumab and **sunitinib malate** (Sutent). This combination therapy is not approved and not recommended.

SIDE EFFECTS

The most common side effects include back pain, dry skin, epistaxis, exfoliative dermatitis, headache, hypertension, lacrimation (excess), proteinuria, rectal hemorrhage, rhinitis, and taste alteration. Major, dose-limiting, and potentially life-threatening side effects include arterial thromboembolic events (e.g., angina, cerebral infarction, MI, TIA), bleeding episodes (e.g., CNS hemorrhage, epistaxis [severe], GI hemorrhage, hemoptysis, vaginal bleeding), CHF, GI perforations (with or without fistula formation [may be complicated by intra-abdominal abscess]), hypertensive crises, infusion reactions, nongastrointestinal fistula formation, ovarian failure, posterior reversible encephalopathy syndrome (PRES), proteinuria with or without nephrotic syndrome, surgery and wound healing complications, and venous thromboembolic events (e.g., deep vein thrombosis, intra-abdominal thrombosis, pulmonary embolism). Other side effects have been reported depending on chemotherapy regimen and include abdominal pain, anal fistula, anorexia, anxiety, arthralgia, asthenia, chest pain, confusion, constipation, cough, diarrhea, dizziness, dysarthria, dysphonia, dyspnea, fatigue, gingival bleeding, hematologic toxicity (e.g., leukopenia, lymphopenia, neutropenia, thrombocytopenia), hemorrhoids, hyperkalemia, hyperglycemia, hypoalbuminemia, hypocalcemia, hypomagnesemia, hyponatremia, increased serum creatinine, infection, insomnia, mucosal inflammation, muscular weakness, myalgia, nail disorder, nasal mucosal disorder, nausea, pain (extremity, neck, pelvic), palmar-plantar erythrodysesthesia syndrome, peripheral edema, peripheral sensory neuropathy, pneumonitis/pulmonary infiltrates, proctalgia, rhinitis, sinusitis, stomatitis, syncope, urinary tract infection, vomiting, weight loss. Additional side effects may occur.

Post-Marketing:

Anastomotic ulceration, gallbladder perforation, GI ulcer, intestinal necrosis, mesenteric venous occlusion, nasal septum perforation, osteonecrosis of the jaw, pancytopenia, polyserositis, pulmonary hypertension, renal thrombotic microangiopathy (manifested as severe proteinuria).

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Patients who develop gastrointestinal vaginal fistula may also have a bowel obstruction and require surgical intervention, as well as a diverting ostomy. Discontinue if any of the following develop: GI perforation (any grade), fistula formation involving any internal organ, formation of any grade tracheoesophageal fistula or any Grade 4 fistula, wound dehiscence or wound healing complications requiring medical intervention, necrotizing fasciitis, Grade 3 or 4 hemorrhage, nephrotic syndrome, a severe arterial thromboembolic event, life-threatening (Grade 4) venous thromboembolic events (including pulmonary embolism), PRES, hypertensive crisis, hypertensive encephalopathy, or CHF. Treat these side effects aggressively; see Dose Adjustments (Dose Modifications for Adverse Reactions), Precautions and Monitor. Discontinue bevacizumab for severe infusion reactions and treat as indicated (e.g., epinephrine, diphenhydramine, IV fluids, oxygen). Temporarily withhold for recent history of hemoptysis, severe hypertension, proteinuria, or less severe infusion reactions as outlined in Dose Adjustments (Dose Modifications for Adverse Reactions). Withhold bevacizumab for at least 28 days before elective surgery (half-life is approximately 20 days but has a wide range). Incision must be fully healed before therapy is resumed.

BEZLOTOXUMAB

(bez-loe-**TOX**-ue-mab)
Zinplava
Monoclonal Antibody
pH 6

USUAL DOSE

A single dose of 10 mg/kg administered as an IV infusion over 60 minutes. The safety and efficacy of repeat administration in patients with *Clostridium difficile* infection (CDI) has not been studied. Administer in conjunction with antibacterial drug treatment for CDI.

DOSE ADJUSTMENTS

None noted. Exposure of bezlotoxumab was not influenced by age, gender, race, comorbid conditions, or renal or hepatic impairment.

DILUTION

Available in a 1,000 mg/40 mL (25 mg/mL) clear to moderately opalescent, colorless to pale yellow solution in a single-dose vial. Withdraw the calculated dose based on the patient's weight, and transfer into an IV bag containing either NS or D5W to prepare a diluted solution with a final concentration of 1 mg/mL to 10 mg/mL. Mix diluted solution by gentle inversion. ***Do not shake.***

For example, a 70-kg patient would require a dose of 700 mg (10 mg/kg × 70 kg). Withdraw 700 mg (28 mL) and transfer to a 100-mL bag of IV solution to prepare a diluted solution with a final concentration of 5.4 mg/mL (700 mg ÷ 128 mL = 5.4 mg/mL).

Filter:

Infuse through a sterile, nonpyrogenic, low–protein binding, 0.2- to 5-micron in-line or add-on filter.

Storage:

Store vials in refrigerator at 2° to 8° C (36° to 46° F). Keep in original carton to protect from light. *Do not freeze or shake vials or diluted solution*. Vials may be stored at RT protected from light for no more than 24 hours. Diluted solution may be stored either at RT for up to 16 hours or refrigerated for up to 24 hours. These time limits include storage of the infusion solution in the IV bag through the duration of the infusion. If refrigerated, allow the diluted solution to come to RT before administration. Discard any unused portion left in the vial.

COMPATIBILITY

Manufacturer states, “Do not coadminister other drugs simultaneously through the same infusion.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 60 minutes. Infuse through a sterile, nonpyrogenic, low–protein binding, 0.2- to 5-micron in-line or add-on filter. May be infused through a peripheral or central line. If diluted solution has been refrigerated, bring to RT before administration.

ACTIONS

A human monoclonal antibody that binds to *C. difficile* toxin B and neutralizes its effects. It does not bind to *C. difficile* toxin A. Bezlotoxumab is eliminated by catabolism and has an elimination half-life of approximately 19 days.

INDICATIONS

To reduce the recurrence of *Clostridium difficile* infection (CDI) in patients 18 years of age or older who are receiving antibacterial drug treatment for CDI and are at a high risk for CDI recurrence.

Limitation of use:

Bezlotoxumab is not indicated for the treatment of CDI. It is not an antibacterial drug and should be used only in conjunction with antibacterial drug treatment of CDI.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Do not administer as an IV push or bolus. ■ Heart failure has been reported. In clinical trials it occurred primarily in patients with underlying congestive heart failure (CHF). In this population there were more deaths in the bezlotoxumab-treated patients than in the placebo-treated patients. In patients with a history of CHF, bezlotoxumab should be reserved for use when benefit outweighs the risk. ■ A protein product; has the potential for immunogenicity.

Monitor:

Monitor for S/S of infusion-related reactions (e.g., dizziness, dyspnea, fatigue, fever, headache, hypertension, and nausea). In clinical trials most reactions were rated as mild to moderate in severity. ■ Monitor for S/S of heart failure.

Patient Education:

Read FDA-approved Patient Information. ■ Use of bezlotoxumab does not take the place of antibacterial treatment for CDI. Antibacterial treatment must be continued as directed.

Maternal/Child:

Information is not available for use during pregnancy or breast-feeding. Use with caution and only if benefit justifies risk. ■ Safety and effectiveness have not been established for use in pediatric patients.

Elderly:

No overall differences in safety and effectiveness have been observed between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

Because bezlotoxumab is eliminated by catabolism, no metabolic drug-drug interactions are expected.

SIDE EFFECTS

The most common side effects reported include fever, headache, and nausea. The most common serious side effect was heart failure. Infusion-related reactions occurring on the day of or on the day after the infusion were reported and included dizziness, dyspnea, fatigue, fever, headache, hypertension, and nausea.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Treat infusion-related reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). There is no clinical experience with overdose.

BIVALIRUDIN

(**by**-val-ih-**ROO**-din)
Anticoagulant (direct thrombin inhibitor)
pH 5 to 6

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Initiate just before percutaneous coronary intervention (PCI). Given in combination with aspirin.

Aspirin:

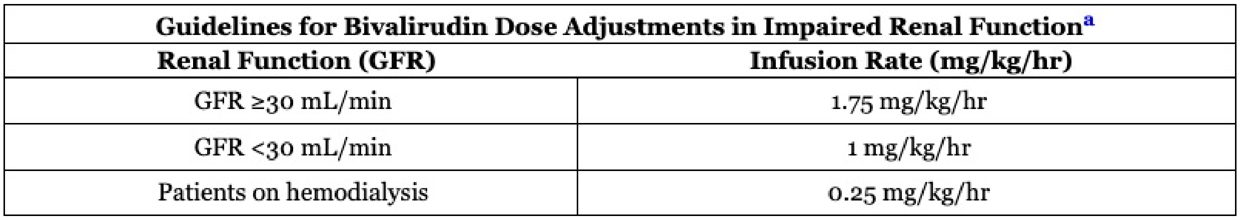
300 to 325 mg before PCI and daily thereafter.

Bivalirudin:

Begin with an IV bolus dose of 0.75 mg/kg. Follow immediately with an infusion at 1.75 mg/kg/hr for the duration of the PCI procedure. Perform an ACT 5 minutes after the bolus dose has been administered. An additional bolus dose of 0.3 mg/kg should be given if needed. See chart in Rate of Administration. Extended duration of infusion following PCI at 1.75 mg/kg/hr for up to 4 hours postprocedure should be considered in patients with ST segment elevation MI (STEMI). May be administered in combination with a glycoprotein IIb/IIIa inhibitor (e.g., eptifibatide, tirofiban) when clinically indicated. Combined use may increase the risk of bleeding.

DOSE ADJUSTMENTS

Reduce infusion rate in impaired renal function as indicated in the following chart. No reduction in the bolus dose is needed.



Guidelines for Bivalirudin Dose Adjustments in Impaired Renal Function[a]

Renal Function (GFR)	Infusion Rate (mg/kg/hr)
GFR ≥30 mL/min	1.75 mg/kg/hr
GFR <30 mL/min	1 mg/kg/hr
Patients on hemodialysis	0.25 mg/kg/hr

[a] The ACT should be monitored in renally impaired patients.

DILUTION

Available in two formulations: (1) a vial containing 250 mg of lyophilized powder, and (2) a refrigerated, ready-to-use premixed vial containing 250 mg/50 mL or 500 mg/100 mL (5 mg/mL).

Vial (lyophilized powder):

Bolus and initial infusion:

Reconstitute each 250-mg vial with 5 mL SWFI. Gently swirl to dissolve. Reconstituted solution is clear to opalescent and colorless to slightly yellow. Each 250-mg vial must be further diluted in 50 mL of D5W or NS. Withdraw and discard 5 mL from a 50-mL infusion bag containing D5W or NS. Add the contents of the reconstituted vial to the infusion bag to yield a final concentration of 5 mg/mL.

Premixed ready-to-use vials:

Once removed from refrigerator, use immediately.

Storage:

Vial (lyophilized powder):

Store unopened vials at CRT. Do not freeze reconstituted or diluted solution. Reconstituted solution stable for 24 hours refrigerated. Concentrations between 0.5 mg/mL and 5 mg/mL are stable at RT for up to 24 hours. Discard unused portion of reconstituted solution.

Premixed ready-to-use vials:

Store in refrigerator between 2° and 8° C (36° and 46° F). Excursions are permitted to 20° to 25° C (68° to 77° F). Avoid excess heat.

COMPATIBILITY

Manufacturer states, "**Do not** administer the following drugs in the same IV line with bivalirudin: Alteplase, amiodarone, amphotericin B (conventional), chlorpromazine, diazepam, dobutamine, prochlorperazine, reteplase, streptokinase, and vancomycin. All are **incompatible** through the same IV line (**Y-site** or piggyback)."

No **incompatibilities** have been observed with administration sets.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

The following chart details, by patient weight in kilograms, the amount of the bolus dose, and the rate in mL/hr of the infusion.

Bivalirudin Dosing Guidelines		
Weight (kg)	Using 5 mg/mL Concentration	
	Bolus (0.75 mg/kg) (mL)	Infusion (1.75 mg/kg/hr) (mL/hr)
43–47	7 mL	16 mL/hr
48–52	7.5 mL	17.5 mL/hr
53–57	8 mL	19 mL/hr
58–62	9 mL	21 mL/hr
63–67	10 mL	23 mL/hr
68–72	10.5 mL	24.5 mL/hr
73–77	11 mL	26 mL/hr
78–82	12 mL	28 mL/hr
83–87	13 mL	30 mL/hr
88–92	13.5 mL	31.5 mL/hr
93–97	14 mL	33 mL/hr
98–102	15 mL	35 mL/hr
103–107	16 mL	37 mL/hr
108–112	16.5 mL	38.5 mL/hr
113–117	17 mL	40 mL/hr
118–122	18 mL	42 mL/hr
123–127	19 mL	44 mL/hr
128–132	19.5 mL	45.5 mL/hr
133–137	20 mL	47 mL/hr
138–142	21 mL	49 mL/hr
143–147	22 mL	51 mL/hr
148–152	22.5 mL	52.5 mL/hr

ACTIONS

An anticoagulant that is a specific and reversible direct thrombin inhibitor. It directly inhibits thrombin by specifically binding both to the catalytic site and to the anion-binding exosite of circulating and clot-bound thrombin. It inhibits coagulant effects by preventing thrombin-mediated cleavage of fibrinogen to fibrin; activation of factors V, VIII, and XIII; and activation of platelets. Exhibits dose- and concentration-dependent anticoagulant activity as evidenced by prolongation of ACT, aPPT, PT and TT. Anticoagulant effect is immediate. Cleared from plasma by a combination of renal mechanisms and proteolytic cleavage. The binding of bivalirudin to thrombin is reversible, resulting in recovery of thrombin active site functions. Coagulation times return to baseline approximately 1 hour after completion of infusion. Half-life averages 25 minutes. 20% of unchanged drug excreted in urine.

INDICATIONS AND USES

An anticoagulant for use in patients undergoing percutaneous coronary intervention (PCI), including patients with heparin-induced thrombocytopenia and heparin-induced thrombocytopenia and thrombosis syndrome. Used concurrently with aspirin.

Unlabeled uses:

Heparin-induced thrombocytopenia (HIT) complicated by thrombosis. ■ Used as a substitute for heparin in patients with acute HIT who require cardiac surgery (e.g., coronary artery bypass graft [CABG]).

CONTRAINDICATIONS

Hypersensitivity to bivalirudin or its components; active major bleeding.

PRECAUTIONS

For IV use only. ■ Most bleeding associated with the use of bivalirudin in PCI occurs at the site of arterial puncture; however, hemorrhage can occur at any site. Consider a hemorrhagic event if there is an unexplained fall in BP or hematocrit and discontinue bivalirudin. ■ Use with caution in disease states and other circumstances in which there is an increased risk of bleeding, including severe hypertension; immediately following lumbar puncture; spinal anesthesia; major surgery, especially involving the brain, spinal cord, or eye; hematologic conditions associated with increased bleeding tendencies such as congenital or acquired bleeding disorders and gastrointestinal lesions such as ulcerations. ■ Has been associated with an increased risk of thrombus formation when used in gamma brachytherapy (percutaneous intracoronary brachytherapy). Fatalities have occurred. Imperative to maintain meticulous catheter technique, with frequent aspiration and flushing to minimize conditions of stasis within the catheter and vessels. ■ Acute stent thrombosis (fewer than 4 hours) has been observed at a greater frequency in bivalirudin-treated patients compared with heparin-treated patients with STEMI undergoing primary PCI. Patients should remain for at least 24 hours in a facility capable of managing ischemic complications and should be carefully monitored following primary PCI for S/S consistent with myocardial ischemia. ■ Half-life extended in patients with impaired renal function; see Dose Adjustments. ■ As with all therapeutic proteins, there is the potential for immunogenicity. ■ See Drug/Lab Interactions.

Monitor:

Before therapy, obtain platelet count, hemoglobin and hematocrit, SCr, ACT, and aPTT. ■ Dose is not titrated to ACT; however, the ACT was checked at 5 minutes and again in 45 minutes during original clinical studies. ■ Monitor anticoagulation status in patients with impaired renal function receiving reduced doses. ■ Observe carefully for symptoms of a hemorrhagic event (e.g., unexplained fall in hematocrit or fall in BP). ■ Monitor patients with disease states associated with an increased risk of bleeding more frequently for bleeding. ■ Monitor STEMI patients undergoing primary PCI for S/S consistent with myocardial ischemia for a minimum of 24 hours following the procedure.

Patient Education:

Risk of bleeding may be increased; discuss medical history and list of all medications (prescription and over-the-counter) with your health care provider; see Drug Interactions. ■ Report all episodes of bleeding. ■ Report tarry stools. ■ Compliance with all measures to minimize bleeding is very important (e.g., avoid use of razors, toothbrushes, other sharp items). ■ Use caution while moving to avoid excess bumping.

Maternal/Child:

Safety for use during pregnancy not established. ■ Not known if bivalirudin is secreted in human milk; use caution if required during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to younger adults. ■ See Dose Adjustments for the elderly with impaired renal function. ■ Bleeding events are more common in the elderly.

DRUG/LAB INTERACTIONS

Coadministration with **heparin, warfarin, thrombolytics, or glycoprotein IIb/IIIa inhibitors** is associated with an increased risk of major bleeding events. ■ Concomitant use with **other agents that alter hemostasis** such as **other anticoagulants** (e.g., enoxaparin, apixaban, rivaroxaban), **nonsteroidal anti-inflammatory drugs, and platelet aggregation inhibitors** (e.g., clopidogrel, prasugrel) may increase the risk of bleeding. ■ Bivalirudin affects INR; therefore INR measurements made in patients who have been treated with bivalirudin may not be useful for determining the appropriate dose of warfarin.

SIDE EFFECTS

Bleeding is the most frequent adverse event; incidence in clinical studies was less than with heparin. Other reported side effects include abdominal pain, angina pectoris, anxiety, back pain, bradycardia, dyspepsia, fever, headache, hypertension, hypotension, injection site pain, insomnia, nausea, nervousness, pain, pelvic pain, thrombocytopenia, urinary retention, and vomiting.

Post-Marketing:

Cardiac tamponade, elevated INR, fatal hemorrhage, hypersensitivity reactions (including anaphylaxis), pulmonary hemorrhage, and thrombus formation during PCI with and without intracoronary brachytherapy, including reports of fatal outcomes.

Overdose:

Bleeding, death due to hemorrhage.

ANTIDOTE

No specific antidote is available. Overdose with or without bleeding may be controlled by discontinuing bivalirudin. Discontinuation leads to a gradual reduction in anticoagulant effects due to metabolism of the drug depending on dose/overdose and concentration achieved. ACT or aPTT should return to normal within 1 to 4 hours after discontinuation. Reversal may take longer in patients with renal impairment. If life-threatening bleeding develops and excessive plasma levels of bivalirudin are suspected, immediately stop infusion. Determine aPTT, ACT, and hemoglobin and prepare for blood transfusion as appropriate. Follow current guidelines for treatment of shock as indicated (fluid, vasopressors [e.g., dopamine], Trendelenburg position, plasma expanders [e.g., albumin, hetastarch]). Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines, corticosteroids, and pressor amines. Bivalirudin is removed by hemodialysis.

BLEOMYCIN SULFATE BBW

(blee-oh-**MY**-sin **SUL**-fayt)
Blenoxane
Antineoplastic (antibiotic)
pH 4.5 to 6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Squamous cell carcinoma, non-Hodgkin lymphoma, testicular carcinoma:

0.25 to 0.5 units/kg of body weight/dose (10 to 20 units/M^2), once or twice weekly (1 unit equals 1 mg). The first two doses in lymphoma patients should not exceed 2 units in order to rule out hypersensitivity.

Hodgkin disease:

Dosage as above. After a 50% response, a maintenance dose of 1 unit daily or 5 units weekly is recommended.

DOSE ADJUSTMENTS

Unit/kg dose based on average weight in presence of edema or ascites. ■ Dose selection in the elderly should be cautious; consider decreased renal function and concomitant disease or drug therapy. ■ Reduce dose in impaired renal function as indicated in the following chart.

CrCl (mL/min)	Bleomycin Dose
50 mL/min and above	100%
40–50 mL/min	70%
30–40 mL/min	60%
20–30 mL/min	55%
10–20 mL/min	45%

5–10 mL/min	40%

DILUTION

Specific techniques required; see Precautions.

Each 15 units or fraction thereof must be reconstituted with 5 mL or more of NS. For IV injection, further dilution is not necessary, but has been further diluted in 50 to 100 mL NS and given as an intermittent infusion. May be given through Y-tube or three-way stopcock of a free-flowing IV.

Filters:

No data available from manufacturer. Another source indicates no significant drug loss with the use of a 0.22-micron filter.

Storage:

Refrigerate powder. Diluted solution stable at room temperature for 24 hours.

COMPATIBILITY

Manufacturer states, “Should not be reconstituted or diluted with D5W or other dextrose-containing diluents.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 15- to 30-unit dose over 10 minutes.

Intermittent infusion:

A single dose over 15 to 30 minutes or 1 unit/minute.

ACTIONS

An antibiotic antineoplastic agent, cell cycle phase-specific, that seems to act by splitting and fragmentation of double-stranded DNA. Inhibits DNA synthesis and, to a lesser extent, RNA and protein synthesis. It localizes in tumors. Improvement usually noted within 2 to 3 weeks. Widely distributed throughout the body. Inactivated by an enzyme that is widely distributed in normal tissue with the exception of the skin and lungs. Half-life is approximately 2 hours. About 60% to 70% excreted in urine.

INDICATIONS AND USES

Testicular carcinoma; may induce complete remission with vinblastine and cisplatin. ■ Palliative treatment, adjunct to surgery or radiation, in patients not responsive to other chemotherapeutic agents or those with squamous cell carcinoma of the skin, head, esophagus, neck, or GU tract, including the cervix, vulva, scrotum, and penis; in

Hodgkin disease and other lymphomas. ■ Injected into pleural cavity to treat malignant pleural effusion.

CONTRAINDICATIONS

Patients who have demonstrated a hypersensitive or idiosyncratic reaction to it.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ May be given by the IM, IV, SC, or IP routes. ■ Administered by or under the direction of the physician specialist. ■ Administer in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ May be used with other antineoplastic drugs to achieve tumor remission. ■ Pulmonary toxicity may progress from nonspecific pneumonitis to pulmonary fibrosis and death. Pulmonary toxicity increases markedly with advancing age or with total doses greater than 400 units but has been seen in younger patients and in patients treated with lower doses. It may occur at lower doses when bleomycin is used in combination with other antineoplastic agents. Risk of developing pulmonary toxicity is greater when O_2 is administered in surgery. To prevent this side effect, it has been recommended that the FiO_2 be maintained at concentrations approximating that of room air during surgery and in the postoperative period. Additionally, fluid replacement should be closely monitored and focus more on colloid (e.g., albumin) administration rather than on crystalloid (e.g., NS, LR) administration. ■ A severe idiosyncratic reaction (similar to anaphylaxis) has been reported in approximately 1% of lymphoma patients. S/S include hypotension, mental confusion, fever, chills, and wheezing; may be immediate or delayed for several hours. More common after the first or second doses. ■ Use with extreme caution in patients with significant renal impairment or compromised pulmonary function.

Monitor:

Obtain a baseline chest x-ray, and recheck every 1 to 2 weeks to detect pulmonary changes. ■ To identify subclinical pulmonary toxicity, monitor pulmonary diffusion capacity for carbon monoxide monthly. Should remain 30% to 35% above pretreatment value. Earliest signs of pulmonary toxicity are rales and dyspnea. ■ Monitor renal, hepatic, and central nervous systems and skin for symptoms of toxicity. ■ Determine patency of vein; avoid extravasation. ■ Maintain adequate hydration. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Observe closely for all signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Acetaminophen, diphenhydramine, and steroids (e.g., hydrocortisone) may be used prophylactically to reduce incidence of fever and anaphylaxis. ■ See Precautions.

Patient Education:

Use effective contraception. ■ Report any possible side effects promptly. ■ Report stinging or burning at IV site promptly. ■ See Appendix D, p. 1311. ■ Pulmonary toxicity more likely in smokers.

Maternal/Child:

Category D: avoid pregnancy. ■ Not recommended during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Volume of distribution and half-life is comparable to that in adults.

Elderly:

Response similar to that seen in younger adults; however, pulmonary toxicity is more common in patients older than 70 years of age. ■ See Dose Adjustments; monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

See Precautions. ■ Vascular toxicities (e.g., myocardial infarction, CVA, thrombotic microangiopathy, cerebral arteritis) or Raynaud's phenomenon have occurred rarely when bleomycin is used in combination with **other antineoplastic agents.** ■ May decrease GI absorption of **digoxin and hydantoins** (e.g., phenytoin). ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Causes sensitization of lung tissue to O_2; increases risk of pulmonary toxicity with **O_2 and general anesthetics.** ■ **Cisplatin** may inhibit renal elimination and increase toxicity.

SIDE EFFECTS

Alopecia, anorexia, chills, dyspnea, fever, hypotension, malaise, nausea, phlebitis (infrequent), rales, scleroderma-like skin changes, stomatitis, tenderness of the skin, tumor site pain, vomiting, weight loss.

Major:

Severe idiosyncratic reaction similar to anaphylaxis (up to 6 hours after test dose), chest pain (acute with sudden onset suggestive of pleuropericarditis), pneumonitis, pulmonary fibrosis, skin toxicity (including nodules on hands, desquamation of skin, hyperpigmentation, and gangrene).

ANTIDOTE

Notify the physician of all side effects. Minor side effects will be treated symptomatically. Discontinue the drug immediately and notify the physician of any symptom of major side effects. Provide immediate treatment (epinephrine and diphenhydramine for anaphylaxis, antibiotics and steroids for pneumonitis) or supportive therapy as indicated.

BLINATUMOMAB BBW

(**BLIN**-a-**TOOM**-oh-mab)
Blincyto
Antineoplastic
Monoclonal antibody
pH 7

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

For both indications, patients weighing 45 kg or more receive a fixed dose. Patients weighing less than 45 kg receive a dose that is calculated using the patient's body surface area (BSA).

Relapsed or refractory B-cell precursor (acute) lymphoblastic leukemia (ALL)

Hospitalization is recommended for the first 9 days of the first cycle and the first 2 days of the second cycle. For all subsequent cycle starts and re-initiation (e.g., if treatment is interrupted for 4 or more hours), supervision by a health care professional or hospitalization is recommended; see Precautions.

Premedication:

Adults:

Administer dexamethasone 20 mg 1 hour before the first dose of blinatumomab of each cycle, 1 hour before a step dose (such as Cycle 1, Day 8), and when restarting an infusion after an interruption of 4 or more hours.

Pediatric patients:

Administer dexamethasone 5 mg/M^2 (to a maximum dose of 20 mg) before the first dose of blinatumomab in the first cycle, before a step dose (such as Cycle 1, Day 8), and when restarting an infusion after an interruption of 4 or more hours in the first cycle.

Blinatumomab dosage:

A treatment course consists of up to 2 cycles for induction followed by 3 additional cycles for consolidation and up to 4 additional cycles of continued therapy. ■ A single cycle of blinatumomab induction or consolidation consists of 28 days of continuous IV infusion followed by a 14-day treatment-free interval (total of 42 days). ■ A single cycle of blinatumomab continued therapy consists of 28 days of continuous IV infusion followed by a 56-day treatment-free interval (total of 84 days). ■ The recommended blinatumomab dosage by patient weight and schedule is provided in the following chart.

Recommended Blinatumomab Dosage and Schedule for the Treatment of Relapsed or Refractory B-Cell Precursor ALL

Cycle	Patient Weight 45 kg or More (Fixed Dose)	Patient Weight Less Than 45 Kg (BSA-Based Dose)
Induction Cycle 1		
Days 1–7 Days 8–28 Days 29–42	9 mcg/day 28 mcg/day 14-day treatment-free interval	5 mcg/M^2/day *(not to exceed 9 mcg/day)* 15 mcg/M^2/day *(not to exceed 28 mcg/day)* 14-day treatment-free interval
Induction Cycle 2		
Days 1–28 Days 29–42	28 mcg/day 14-day treatment-free interval	15 mcg/M^2/day *(not to exceed 28 mcg/day)* 14-day treatment-free interval
Consolidation Cycles 3–5		
Days 1–28 Days 29–42	28 mcg/day 14-day treatment-free interval	15 mcg/M^2/day *(not to exceed 28 mcg/day)* 14-day treatment-free interval
Continued Therapy Cycles 6–9		
Days 1–28 Days 29–84	28 mcg/day 56-day treatment-free interval	15 mcg/M^2/day *(not to exceed 28 mcg/day)* 56-day treatment-free interval

Treatment of Minimal Residual Disease (MRD)–Positive B-cell Precursor (ALL)

Hospitalization is recommended for the first 3 days of the first cycle and for the first 2 days of the second cycle. For all subsequent cycle starts and re-initiation (e.g., if treatment is interrupted for 4 or more hours), supervision by a health care professional or hospitalization is recommended; see Precautions.

Premedication:

Adults:

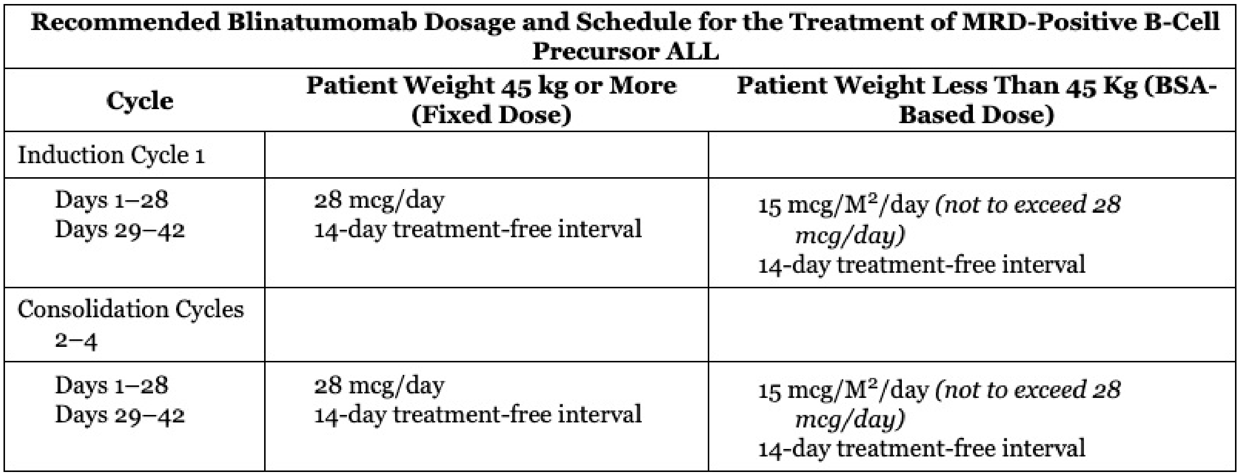
Administer prednisone 100 mg IV or equivalent (e.g., dexamethasone 16 mg) 1 hour before the first dose of blinatumomab in each cycle.

Pediatric patients:

Administer dexamethasone 5 mg/M^2 (to a maximum dose of 20 mg) before the first dose of blinatumomab in the first cycle and when restarting an infusion after an interruption of 4 or more hours in the first cycle.

Blinatumomab dosage:

A treatment course consists of 1 cycle for induction followed by up to 3 additional cycles for consolidation. ■ A single cycle of blinatumomab induction or consolidation consists of 28 days of continuous IV infusion followed by a 14-day treatment-free interval (total of 42 days). ■ The recommended blinatumomab dosage by patient weight and schedule is provided in the following chart.

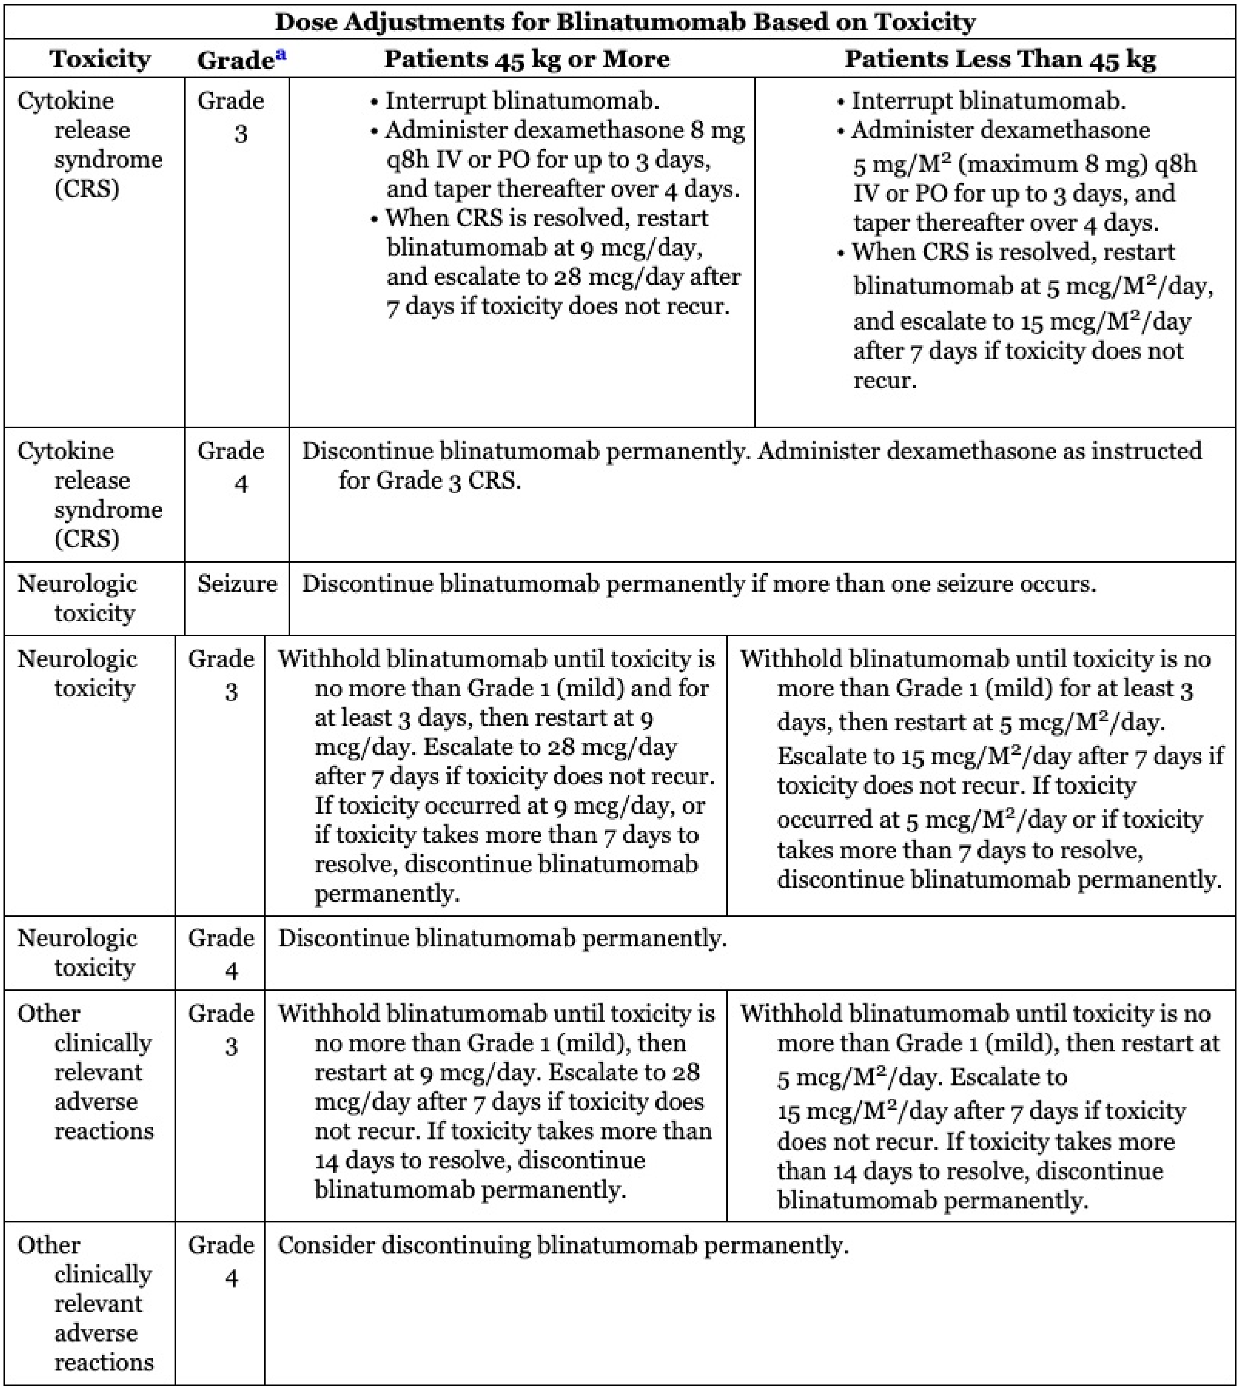


Recommended Blinatumomab Dosage and Schedule for the Treatment of MRD-Positive B-Cell Precursor ALL

Cycle	**Patient Weight 45 kg or More (Fixed Dose)**	**Patient Weight Less Than 45 Kg (BSA-Based Dose)**
Induction Cycle 1		
Days 1–28 Days 29–42	28 mcg/day 14-day treatment-free interval	15 mcg/M^2/day *(not to exceed 28 mcg/day)* 14-day treatment-free interval
Consolidation Cycles 2–4		
Days 1–28 Days 29–42	28 mcg/day 14-day treatment-free interval	15 mcg/M^2/day *(not to exceed 28 mcg/day)* 14-day treatment-free interval

DOSE ADJUSTMENTS

For an interruption of no longer than 7 days, continue the same cycle to a total of 28 days of infusion, including the days before and after the interruption in that cycle. If an interruption due to an adverse event is longer than 7 days, start a new cycle. ■ No dose adjustment is needed for patients with a baseline CrCl equal to or greater than 30 mL/min. No information is available for patients with a CrCl less than 30 mL/min or for patients on hemodialysis.



Dose Adjustments for Blinatumomab Based on Toxicity

Toxicity	Grade[a]	Patients 45 kg or More	Patients Less Than 45 kg
Cytokine release syndrome (CRS)	Grade 3	• Interrupt blinatumomab. • Administer dexamethasone 8 mg q8h IV or PO for up to 3 days, and taper thereafter over 4 days. • When CRS is resolved, restart blinatumomab at 9 mcg/day, and escalate to 28 mcg/day after 7 days if toxicity does not recur.	• Interrupt blinatumomab. • Administer dexamethasone 5 mg/M^2 (maximum 8 mg) q8h IV or PO for up to 3 days, and taper thereafter over 4 days. • When CRS is resolved, restart blinatumomab at 5 mcg/M^2/day, and escalate to 15 mcg/M^2/day after 7 days if toxicity does not recur.
Cytokine release syndrome (CRS)	Grade 4	Discontinue blinatumomab permanently. Administer dexamethasone as instructed for Grade 3 CRS.	
Neurologic toxicity	Seizure	Discontinue blinatumomab permanently if more than one seizure occurs.	
Neurologic toxicity	Grade 3	Withhold blinatumomab until toxicity is no more than Grade 1 (mild) and for at least 3 days, then restart at 9 mcg/day. Escalate to 28 mcg/day after 7 days if toxicity does not recur. If toxicity occurred at 9 mcg/day, or if toxicity takes more than 7 days to resolve, discontinue blinatumomab permanently.	Withhold blinatumomab until toxicity is no more than Grade 1 (mild) for at least 3 days, then restart at 5 mcg/M^2/day. Escalate to 15 mcg/M^2/day after 7 days if toxicity does not recur. If toxicity occurred at 5 mcg/M^2/day or if toxicity takes more than 7 days to resolve, discontinue blinatumomab permanently.
Neurologic toxicity	Grade 4	Discontinue blinatumomab permanently.	
Other clinically relevant adverse reactions	Grade 3	Withhold blinatumomab until toxicity is no more than Grade 1 (mild), then restart at 9 mcg/day. Escalate to 28 mcg/day after 7 days if toxicity does not recur. If toxicity takes more than 14 days to resolve, discontinue blinatumomab permanently.	Withhold blinatumomab until toxicity is no more than Grade 1 (mild), then restart at 5 mcg/M^2/day. Escalate to 15 mcg/M^2/day after 7 days if toxicity does not recur. If toxicity takes more than 14 days to resolve, discontinue blinatumomab permanently.
Other clinically relevant adverse reactions	Grade 4	Consider discontinuing blinatumomab permanently.	

[a] Based on the Common Terminology Criteria for Adverse Events (CTCAE). Grade 3 is severe, and Grade 4 is life-threatening.

DILUTION

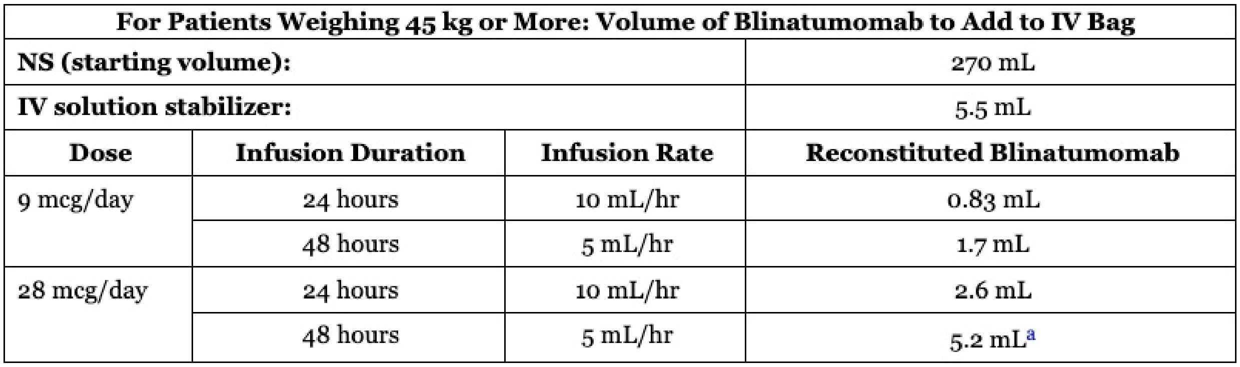
To minimize medication errors, including underdose and overdose, it is imperative that the instructions for preparation (including admixing) and administration be followed exactly. Blinatumomab may be infused over 24 or 48 hours (preservative-free) or 7 days (with preservative). The choice between these options should be made by the treating physician. However, the 7-day infusion is not recommended for patients under 22 kg. Aseptic technique must be strictly observed. Consult the prescribing information before preparation begins and again if questions arise during reconstitution, preparation, or administration. Contact manufacturer if needed. Available in a package that includes a 35-mcg vial of blinatumomab and a vial of IV solution stabilizer. The IV stabilizer is used to prevent adhesion of blinatumomab to IV bags and IV lines. ***Do not reconstitute blinatumomab with the IV solution stabilizer.***

Reconstitution of blinatumomab:

Reconstitute one vial of blinatumomab using 3 mL of preservative-free SWFI. Direct SWFI toward the side of the vial. Gently swirl contents to avoid excess foaming. ***Do not shake.*** Final blinatumomab concentration is 12.5 mcg/mL. Solution should be clear to slightly opalescent and colorless to slightly yellow. ***Do not use if solution is cloudy or has precipitated.***

Preparation of Blinatumomab Infusion Bag for 24- or 48-hour Infusion:

1. **To minimize errors, use the specific volumes described in the following charts to prepare blinatumomab infusion bag.**
2. Add **270 mL NS** to a polyolefin, PVC DEHP-free, or ethyl vinyl acetate (EVA) infusion bag.
3. Transfer **5.5 mL** of the IV solution stabilizer to the IV bag of NS. Gently mix to avoid foaming. Discard remaining IV solution stabilizer.
4. Transfer the required volume of the reconstituted solution of blinatumomab into the IV bag containing the NS and stabilizer. Gently mix the contents of the bag to avoid foaming.
5. Under aseptic conditions, attach the polyolefin, PVC DEHP-free, or EVA IV tubing to the IV bag with the sterile, 0.2-micron, in-line filter. ***Remove air from the IV bag, and prime the IV line only with the prepared solution for infusion. Do not prime with NS.***



For Patients Weighing 45 kg or More: Volume of Blinatumomab to Add to IV Bag			
NS (starting volume):			270 mL
IV solution stabilizer:			5.5 mL
Dose	**Infusion Duration**	**Infusion Rate**	**Reconstituted Blinatumomab**
9 mcg/day	24 hours	10 mL/hr	0.83 mL
	48 hours	5 mL/hr	1.7 mL
28 mcg/day	24 hours	10 mL/hr	2.6 mL
	48 hours	5 mL/hr	5.2 mL[a]

[a] Two packages of blinatumomab are needed for preparation of 28 mcg/day dose infused over 48 hours at a rate of 5 mL/hr.

For Patients Weighing Less Than 45 kg: Volume of Blinatumomab to Add to IV Bag for 5 mcg/M²/day Dose

NS (starting volume):				270 mL
IV solution stabilizer:				5.5 mL
Dose	**Infusion Duration**	**Infusion Rate**	**BSA (M²)**	**Reconstituted Blinatumomab**
5 mcg/M²/day	24 hours	10 mL/hr	1.5–1.59	0.7 mL

			0.6–0.69	1.7 mL
			0.5–0.59	1.4 mL
			0.4–0.49	1.2 mL

[a] Two packages of blinatumomab are needed for preparation of 15 mcg/M^2/day dose infused over 48 hours at a rate of 5 mL/hr with a BSA greater than 1.09 M^2.

Preparation of Blinatumomab Infusion Bag for 7-day Infusion:

1. **To minimize errors, use the specific volumes described in the following chart to prepare blinatumomab infusion bag.**
2. Add **90 mL *bacteriostatic NS*** to an empty polyolefin, PVC DEHP-free, or

ethyl vinyl acetate (EVA) infusion bag.

3. Transfer **2.2 mL** of the IV solution stabilizer to the IV bag of NS. Gently mix to avoid foaming. Discard remaining IV solution stabilizer.
4. Transfer the required volume of the reconstituted solution of blinatumomab into the IV bag containing the NS and stabilizer. Gently mix the contents of the bag to avoid foaming.
5. **Add NS, USP to the IV bag to make a final volume of 110 mL, resulting in 0.74% benzyl alcohol.** (Required volume of additional NS is specified in the following chart.) Gently mix to avoid foaming.
6. Under aseptic conditions, attach the polyolefin, PVC DEHP-free, or EVA IV tubing to the IV bag. The in-line filter is not required for a 7-day bag. ***Remove air from the IV bag and prime the IV line only with the prepared solution for infusion. Do not prime with NS.***

For 7-Day Infusion: Volumes to Add to IV Bag for 28 mcg/day and 15 mcg/M²/day (Not Recommended for Patients Under 22 kg)					
Bacteriostatic NS (starting volume):				90 mL	
IV solution stabilizer:				2.2 mL	
Reconstituted blinatumomab:				Specific volume listed below	
Quantity sufficient (Q.S.) with NS, USP to a Final Volume of 110 mL					
Infusion duration:				7 days	
Infusion rate:				0.6 mL/hr	
Patient Weight	**Dose**	**BSA (M²)**	**Number of Blinatumomab Packages**	**Reconstituted Blinatumomab**	**NS, USP to Q.S. to a Final Volume of 110 mL**
≥45 kg *(Fixed dose)*	28 mcg/day		6	16.8 mL	1 mL
22–45 kg *(BSA-based dosing)*	15 mcg/M²/day	1.5–1.59	5	14 mL	3.8 mL
		1.4–1.49	5	13.1 mL	4.7 mL
		1.3–1.39	5	12.2 mL	5.6 mL
		1.2–1.29	5	11.3 mL	6.5 mL
		1.1–1.19	4	10.4 mL	7.4 mL
		1–1.09	4	9.5 mL	8.3 mL
		0.9–0.99	4	8.6 mL	9.2 mL

Filters:

24- and 48-hour infusion bags must be administered using polyolefin, PVC DEHP-free, or ethyl vinyl acetate (EVA) IV tubing that contains a sterile, low–protein-binding, 0.2-

micron, in-line filter. The 7-day infusion bag does not require a filter.

Storage:

Refrigerate vials of blinatumomab and IV solution stabilizer at 2° to 8° C (36° to 46° F) in the original package and protect from light until time of use. May be stored for a maximum of 8 hours at RT in the original carton. Do not freeze. If not used immediately, the reconstituted vial may be refrigerated for up to 24 hours or kept at room temperature (23° to 27° C [73° to 81° F]) for up to 4 hours. A preservative-free prepared infusion bag (for 24-hour or 48-hour infusion) may be refrigerated for up to 8 days or kept at room temperature for up to 48 hours. A 7-day infusion bag (with preservative) may be refrigerated for up to 14 days or kept at RT for up to 7 days. Storage times **include** infusion time. Discard if not administered within the maximum time frames for storage. Do not return solution that has been stored at RT to the refrigerator.

COMPATIBILITY

Manufacturer states, "When administered via a multilumen venous catheter, blinatumomab should be infused through a dedicated lumen." Blinatumomab is **incompatible** with DEHP. Use polyolefin, PVC DEHP-free, or ethyl vinyl acetate (EVA) infusion bags/pump cassettes and tubing sets.

RATE OF ADMINISTRATION

Do not flush the blinatumomab infusion line or IV catheter, especially when changing infusion bags. Flushing when changing bags or at completion of the infusion can result in overdose. Administer as a continuous IV infusion over 24 or 48 hours or 7 days at a constant flow rate using a programmable, lockable, nonelastomeric infusion pump with an alarm. The final volume of the infusion solution (270 mL or 110 mL) will be more than the volume administered to the patient to account for the priming of the IV tubing and to ensure that the patient will receive the full dose of blinatumomab.

24-hour infusion:

A complete dose delivered at 10 mL/hr.

48-hour infusion:

A complete dose delivered at 5 mL/hr.

7-day infusion:

A complete dose delivered at 0.6 mL/hr.

ACTIONS

Blinatumomab is produced by recombinant technology. It is a bispecific, CD19-directed, CD3T-cell engager that binds to CD19 expressed on cells of B-lineage origin and to CD3 expressed on T-cells. It activates endogenous T-cells by connecting CD3 in the T-cell receptor (TCR) complex with CD19 on benign and malignant B-cells. Through various processes it results in redirected lysis of CD19+ cells. During the continuous intravenous infusion (over 4 weeks), the pharmacodynamics response was characterized by T-cell activation and initial redistribution, reduction in peripheral B-cells, and transient cytokine elevation. The highest elevation of cytokines occurs during the first 2 days following the initiation of dosing and usually returns to baseline within 24 to 48 hours. In subsequent cycles, cytokine elevation is less intense. With a continuous infusion, steady-state serum concentration was achieved within a day and remained stable over time during studies. Metabolic pathway has not been characterized. Degradation into small peptides and amino acids via catabolic pathways is suspected. Half-life was 2.10 hours. Negligible amounts excreted in urine.

INDICATIONS AND USES

Treatment of relapsed or refractory B-cell precursor acute lymphoblastic leukemia (ALL) in adults and pediatric patients. ■ Treatment of B-cell precursor acute lymphoblastic leukemia (ALL) in first or second complete remission with minimal residual disease (MRD) greater than or equal to 0.1% in adults and pediatric patients. (This indication is approved under accelerated approval based on MRD response rate and hematologic relapse-free survival. Continued approval for this indication may be contingent on verification and description of clinical benefit in the confirmatory trials.)

CONTRAINDICATIONS

Known hypersensitivity to blinatumomab or to any component of the product formulation.

PRECAUTIONS

Administered under the direction of a physician or health care professional knowledgeable in its use. Adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency should be available; see Usual Dose. ■ Cytokine release syndrome (CRS), which may be life-threatening or fatal, has occurred. Interrupt or discontinue blinatumomab and treat with corticosteroids as recommended. ■ The manifestations of CRS after treatment overlap with those of infusion reactions, capillary leak syndrome (CLS), and hemophagocytic histiocytosis/macrophage activation syndrome (MAS). In clinical trials, all of these terms were used to define CRS. ■ Neurologic toxicities that may be severe, life-threatening, or fatal have occurred. Interrupt or discontinue blinatumomab as recommended. There is limited experience with blinatumomab in patients with active ALL in the CNS or a history of neurologic events. Patients with a history of or presence of clinically relevant CNS pathology were excluded form clinical studies. ■ Serious infections (e.g., bacteremia, catheter-site infections, opportunistic infections, pneumonia, sepsis) were observed in 25% of patients in clinical studies; some were life-threatening or fatal. ■ Tumor lysis syndrome (TLS), which may be life-threatening or fatal, has been observed. ■ Neutropenia and febrile neutropenia, including life-threatening cases, have been observed. ■ Transient elevation in liver enzymes has been seen in isolation and in conjunction with CRS. ■ Fatal pancreatitis has been reported in patients receiving blinatumomab in combination with dexamethasone. ■ Changes showing leukoencephalopathy have been identified by cranial MRI, especially in patients with prior treatment with cranial irradiation and antileukemic chemotherapy (including systemic high-dose methotrexate or intrathecal cytarabine). Clinical significance unknown. ■ Preparation and administration errors have occurred; follow instructions carefully. ■ No formal pharmacokinetic studies have been conducted in patients with hepatic or renal impairment. ■ A therapeutic protein, there is a potential for immunogenicity. Notify manufacturer if anti-blinatumomab antibodies with a clinically significant effect are suspected.

Monitor:

Obtain baseline CBC (including, but not limited to, WBC and ANC). Repeat during each cycle as indicated. ■ Obtain baseline ALT, AST, GGT, and total bilirubin. Repeat during treatment as indicated; see Antidote. ■ Monitor for S/S of CRS (e.g., asthenia; disseminated intravascular coagulation (DIC); fever; headache; hypotension; increased ALT, AST, and total bilirubin; nausea). The median time to onset of CRS was 2 days after the start of infusion; see Precautions. ■ Monitor for S/S of neurologic toxicities (e.g., confusion and disorientation, convulsions, coordination and balance disorders, disturbances in consciousness, encephalopathy, headache, speech disorders, tremor). Manifestations of neurologic toxicity include cranial nerve disorders. In clinical studies, neurologic toxicities occurred in approximately 65% of patients, with Grade 3 or higher events occurring in 13% of patients. The median time to onset was within the first 2 weeks. Most events resolved with treatment interruption, but some resulted in discontinuation of blinatumomab. ■ Observe closely for S/S of infection (e.g., chills, cough, fever, pain with urination). Prophylactic antibiotics and surveillance testing during treatment may be indicated. Treat appropriately. ■ Monitor for S/S of hypersensitivity (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing) or S/S of an infusion reaction (e.g., breathing problems, chills, fever, or rash). ■ Monitor for S/S of TLS (e.g., hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure). Flank pain and hematuria are early signs. To prevent TLS, initiate appropriate prophylactic measures, including pretreatment nontoxic cytoreduction and on-treatment hydration. Management may require temporary interruption or discontinuation of blinatumomab. ■ Monitor for S/S of pancreatitis (e.g., elevated amylase, nausea, vomiting, upper abdominal pain).

Patient Education:

Read FDA-approved medication guide. ■ Verify pregnancy status of females of reproductive potential before initiating therapy. Effective contraception required during treatment and for at least 48 hours after the last dose of blinatumomab. ■ Keep the area around the intravenous catheter clean to reduce the risk of infection. ■ Do not adjust the setting on the infusion pump; may result in dosing errors. Notify the doctor or nurse immediately if there is a problem with the infusion pump or the pump alarms. ■ There is a risk of seizures or a loss of consciousness. Refrain from driving and/or engaging in hazardous occupations or activities (e.g., operating heavy or potentially dangerous machinery). ■ Promptly report S/S that may be associated with cytokine release syndrome and infusion reactions (e.g., chills, fatigue, fever, hypotension, nausea and vomiting, rash, wheezing). ■ Promptly report S/S of neurologic toxicities (e.g., confusion, convulsions, speech disorders) and S/S of infection, including pneumonia. ■ Promptly report S/S of pancreatitis (e.g., severe and persistent stomach pain, with or without nausea and vomiting. ■ See Appendix D.

Maternal/Child:

Based on its mechanism of action, blinatumomab may cause fetal harm, including B-cell lymphocytopenia, when administered to a pregnant woman. Because of the potential for B-cell lymphocytopenia in infants after exposure to blinatumomab in utero, an infant's B-lymphocytes should be monitored before the initiation of live virus vaccination. ■ Discontinue breast-feeding during and for at least 48 hours after treatment with blinatumomab. ■ Safety and efficacy have been established in pediatric patients with relapsed or refractory B-cell precursor ALL, and accelerated approval has been given for MRD-positive B-cell precursor ALL. Overall, the adverse reactions reported in blinatumomab-treated pediatric patients were similar in type to those seen in adults. However, some reactions were reported more frequently and/or presented differently in pediatric patients; see prescribing information. ■ Serious and fatal adverse reactions, including "gasping syndrome," can occur in neonates and infants treated with benzyl alcohol–preserved drugs, including blinatumomab (with preservative). When prescribing blinatumomab (with preservative) for pediatric patients, consider the combined daily metabolic load of benzyl alcohol from all sources, including blinatumomab (with preservative, which contains 7.4 mg of benzyl alcohol per mL) and any other drugs that contain benzyl alcohol. The minimum amount of benzyl alcohol at which serious adverse reactions may occur is not known. Due to the addition of bacteriostatic saline, 7-day bags of blinatumomab solution for infusion are not recommended for use in any patient weighing less than 22 kg.

Elderly:

Safety and effectiveness similar to that seen in younger adults. The elderly experienced a higher rate of serious infections and neurologic toxicities, including cognitive disorder, confusion, and encephalopathy.

DRUG/LAB INTERACTIONS

No formal drug interaction studies have been conducted. ■ Initiation of blinatumomab treatment causes transient release of cytokines that **may suppress CYP_{450} enzymes**. Highest risk is during the first 9 days of the first cycle and the first 2 days of the second cycle in patients receiving concomitant CYP_{450} substrates, particularly those with a narrow therapeutic index. Monitor these patients for toxicity (e.g., warfarin [Coumadin]) or drug concentrations (e.g., cyclosporine [Sandimmune]) and adjust the dose of the concomitant drug as needed. ■ Safety of immunization with live viral vaccines during or after blinatumomab therapy has not been studied. Vaccination with live virus vaccines is not recommended for at least 2 weeks before the start of blinatumomab treatment, during treatment, and until immune recovery after the last cycle of blinatumomab.

SIDE EFFECTS

Anemia, chills, febrile neutropenia, fever, headache, infections (bacterial and pathogen unspecified), infusion-related reactions, neutropenia, thrombocytopenia, and tremor are most common. Cytokine release syndrome, neurologic toxicities (including cranial nerve disorders), infections, tumor lysis syndrome, elevated liver enzymes, neutropenia and febrile neutropenia, pancreatitis, and leukoencephalopathy are the most serious side effects. Other reported side effects include abdominal pain, aphasia, arrhythmia, arthralgia, back pain, bone pain, chest pain, constipation, cough, decreased appetite, decreased immunoglobulins, diarrhea, dizziness, dyspnea, encephalopathy, fatigue, hyperglycemia, hypersensitivity reactions, hypertension, hypertransaminasemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypotension, insomnia, leukopenia, nausea, pain in an extremity, peripheral edema, rash, vomiting, and weight increase. Many other side effects occurred in lesser percentages of patients.

Post-Marketing:

Fatal pancreatitis (in combination with dexamethasone).

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Supportive therapy as indicated will help sustain the patient in toxicity. Interrupt the infusion and/or discontinue blinatumomab for cytokine release syndrome, neurologic toxicities, pancreatitis, and/or tumor lysis syndrome; see Dose Adjustments. Management of CRS and pancreatitis may include administration of dexamethasone. Interrupt the infusion for prolonged neutropenia, transaminases greater than 5 times the ULN, a bilirubin more than 3 times the ULN, or other clinically relevant adverse reactions. Discontinue blinatumomab as outlined in Dose Adjustments. In the event of overdose, interrupt the infusion, monitor the patient for signs of toxicity, and provide supportive care. Consider re-initiation of blinatumomab at the correct therapeutic dose when all toxicities have resolved and no earlier than 12 hours after interruption of the infusion. Treat an infusion reaction as indicated. Treat a hypersensitivity reaction immediately with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

BORTEZOMIB

(bore-**TEH**-zo-mib)
Velcade
Antineoplastic
pH 2 to 6.5

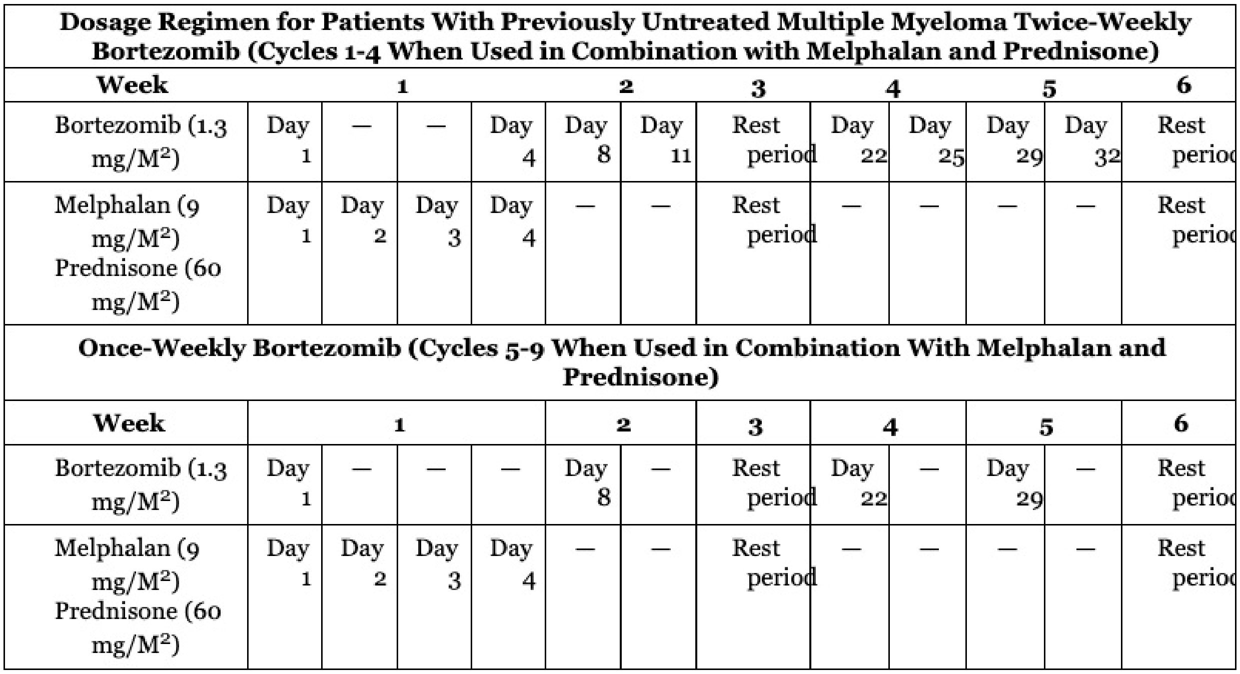
USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Previously untreated multiple myeloma:

1.3 mg/M^2/dose as an IV bolus. Given in combination with oral melphalan and oral prednisone for nine 6-week cycles as outlined in the following chart. For Cycles 1 to 4, administer twice weekly (Days 1, 4, 8, 11, 22, 25, 29, 32). For Cycles 5 to 9, administer once weekly (Days 1, 8, 22, 29). At least 72 hours should elapse between consecutive doses of bortezomib.



<table>

</table>

Previously untreated mantle cell lymphoma:

1.3 mg/M^2/dose as an IV bolus. Given in combination with intravenous rituximab, cyclophosphamide, doxorubicin, and oral prednisone (VcR-CAP) for six 3-week cycles as outlined in the following chart. Bortezomib is administered first, followed by rituximab. Bortezomib is administered twice weekly for 2 weeks (Days 1, 4, 8, 11), followed by a 10-day rest period on Days 12 to 21. For patients with a response first documented at Cycle

6, two additional VcR-CAP cycles are recommended. At least 72 hours should elapse between consecutive doses of bortezomib.

Dosage Regimen for Patients With Previously Untreated Mantle Cell Lymphoma								
Twice Weekly Bortezomib (Six 3-week Cycles)[a]								
Week	**1**					**2**		**3**
Bortezomib (1.3 mg/M^2)	Day 1	—	—	Day 4	—	Day 8	Day 11	Rest period
Rituximab (375 mg/M^2) Cyclophosphamide (750 mg/M^2) Doxorubicin (50 mg/M^2)	Day 1	—	—	—	—	—	—	Rest period
Prednisone (100 mg/M^2)	Day 1	Day 2	Day 3	Day 4	Day 5	—	—	Rest period

[a] Dosing may continue for 2 more cycles (for a total of 8 cycles) if response is first seen at Cycle 6.

Relapsed multiple myeloma and relapsed mantle cell lymphoma:

1.3 mg/M^2/dose as an IV bolus 2 times a week for 2 weeks (Days 1, 4, 8, and 11). Follow with a 10-day rest period (Days 12 through 21). At least 72 hours should elapse between doses of bortezomib (e.g., Days 1, 4, 8, and 11). A treatment cycle is 21 days. See Dose Adjustments. For extended therapy of more than 8 cycles, bortezomib may be administered on the above standard schedule or, for relapsed multiple myeloma, on a maintenance schedule of once weekly for 4 weeks (Days 1, 8, 15, and 22), followed by a 13-day rest period (Days 23 to 35).

Patients with multiple myeloma who have previously responded to treatment with bortezomib (either alone or in combination) and who have relapsed at least 6 months after their prior therapy may be started on bortezomib at the last tolerated dose. Retreated patients are administered bortezomib twice weekly (Days 1, 4, 8, and 11) every 3 weeks for a maximum of 8 cycles. At least 72 hours should elapse between consecutive doses of bortezomib. Bortezomib may be administered either alone or in combination with dexamethasone.

Combination therapy in multiple myeloma (unlabeled in bortezomib prescribing information):

Bortezomib:

Administer 1.3 mg/M^2 as an IV bolus on Days 1, 4, 8, and 11 every 3 weeks.

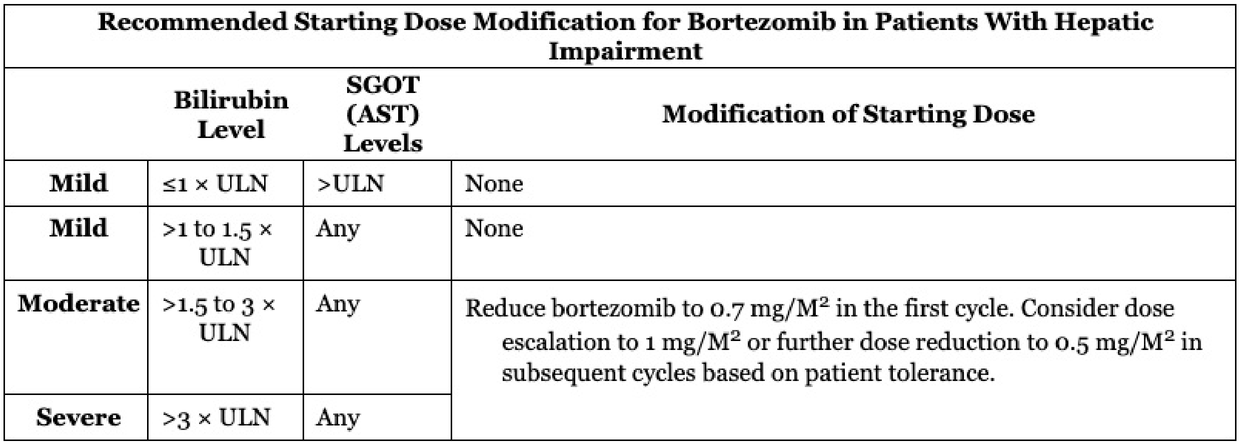
Doxil:

Administer 30 mg/M^2 on Day 4 following bortezomib. Continue for up to 8 cycles until disease progression or the occurrence of unacceptable toxicity.

DOSE ADJUSTMENTS

Dose adjustments are based on clinical toxicities. ■ Starting dose adjustments are not required for patients with renal insufficiency, including those requiring dialysis.

Bortezomib may be partially removed by dialysis. Administer after dialysis. ■ No significant difference in the pharmacokinetics of bortezomib based on age, sex, or renal impairment; see Precautions. ■ See the following charts for recommended starting dose modifications for patients with moderate to severe hepatic impairment; dose adjustments in combination therapy with melphalan and prednisone; dose adjustments in combination therapy with rituximab, cyclophosphamide, doxorubicin, and prednisone; dose adjustments in relapsed multiple myeloma and mantle cell lymphoma; and dose modifications for bortezomib-related neuropathic pain and/or peripheral sensory or motor neuropathy.

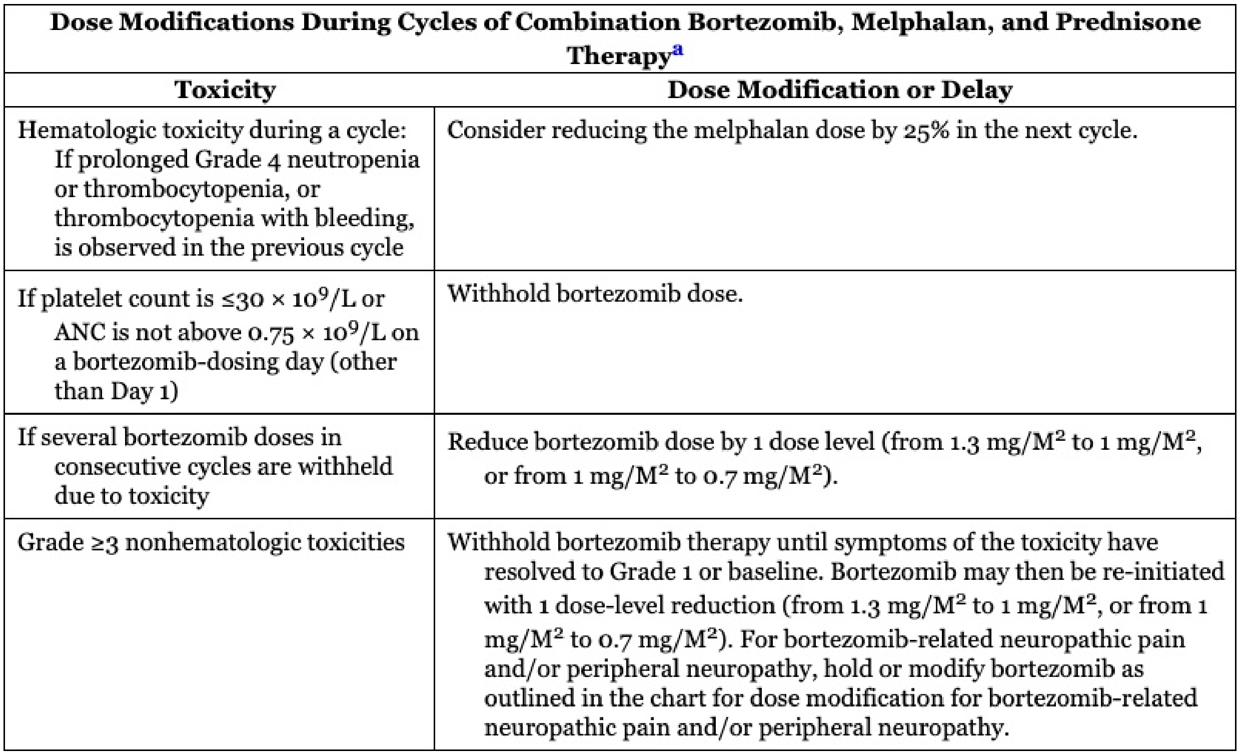


Recommended Starting Dose Modification for Bortezomib in Patients With Hepatic Impairment

	Bilirubin Level	SGOT (AST) Levels	Modification of Starting Dose
Mild	≤1 × ULN	>ULN	None
Mild	>1 to 1.5 × ULN	Any	None
Moderate	>1.5 to 3 × ULN	Any	Reduce bortezomib to 0.7 mg/M² in the first cycle. Consider dose escalation to 1 mg/M² or further dose reduction to 0.5 mg/M² in subsequent cycles based on patient tolerance.
Severe	>3 × ULN	Any	

Combination therapy with melphalan and prednisone in previously untreated multiple myeloma:

Before each treatment cycle, platelet count should be equal to or greater than 70 × 10^9/L, and ANC should be equal to or greater than 1 × 10^9/L. Nonhematologic toxicities should have resolved to Grade 1 or baseline. Dose modifications for subsequent cycles are outlined in the following chart.



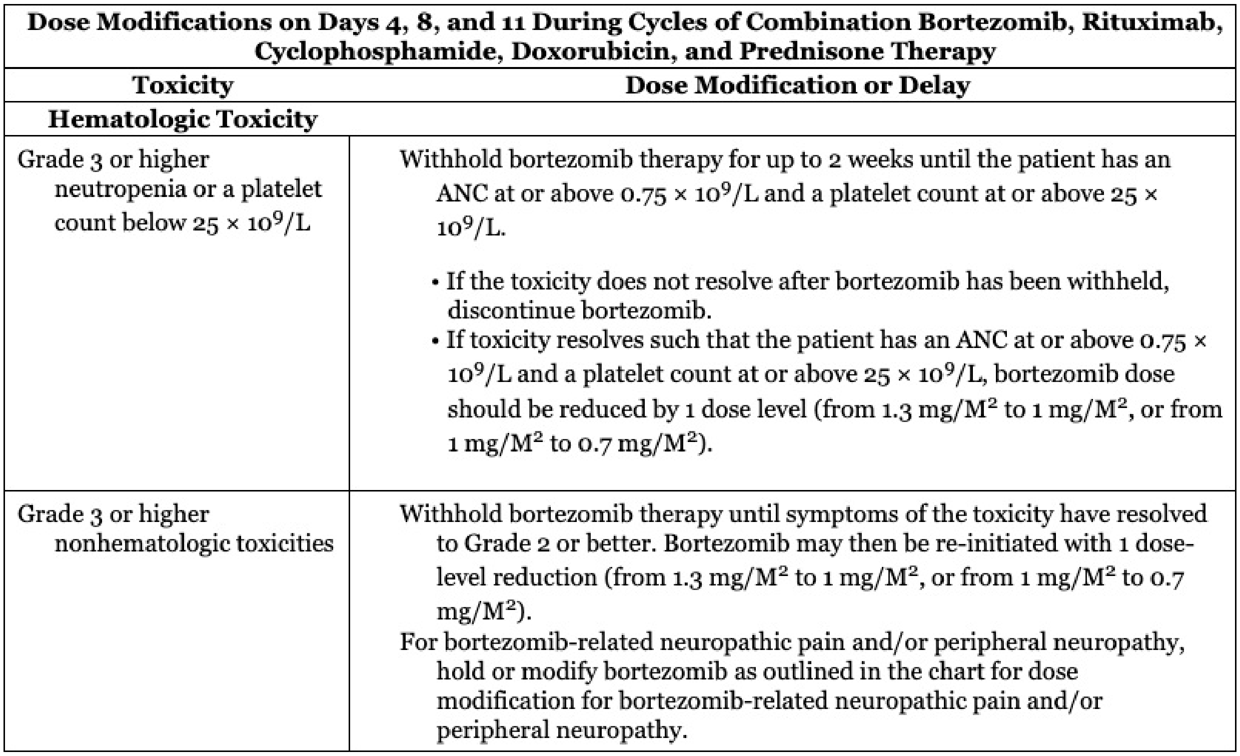
Dose Modifications During Cycles of Combination Bortezomib, Melphalan, and Prednisone Therapy[a]

Toxicity	Dose Modification or Delay
Hematologic toxicity during a cycle: If prolonged Grade 4 neutropenia or thrombocytopenia, or thrombocytopenia with bleeding, is observed in the previous cycle	Consider reducing the melphalan dose by 25% in the next cycle.
If platelet count is $\leq 30 \times 10^9$/L or ANC is not above 0.75×10^9/L on a bortezomib-dosing day (other than Day 1)	Withhold bortezomib dose.
If several bortezomib doses in consecutive cycles are withheld due to toxicity	Reduce bortezomib dose by 1 dose level (from 1.3 mg/M^2 to 1 mg/M^2, or from 1 mg/M^2 to 0.7 mg/M^2).
Grade ≥ 3 nonhematologic toxicities	Withhold bortezomib therapy until symptoms of the toxicity have resolved to Grade 1 or baseline. Bortezomib may then be re-initiated with 1 dose-level reduction (from 1.3 mg/M^2 to 1 mg/M^2, or from 1 mg/M^2 to 0.7 mg/M^2). For bortezomib-related neuropathic pain and/or peripheral neuropathy, hold or modify bortezomib as outlined in the chart for dose modification for bortezomib-related neuropathic pain and/or peripheral neuropathy.

[a] Graded according to Common Terminology Criteria for Adverse Events (CTCAE).

Combination therapy with IV rituximab, cyclophosphamide, doxorubicin, and oral prednisone in previously untreated mantle cell lymphoma:

Before the first day of each cycle (other than Cycle 1), platelet count should be equal to or greater than 100×10^9/L, and ANC should be equal to or greater than 1.5×10^9/L. Hemoglobin should be equal to or greater than 8 g/dL, and nonhematologic toxicities should have resolved to Grade 1 or baseline. Dose modifications for Days 4, 8, and 11 are outlined in the following chart.



Dose Modifications on Days 4, 8, and 11 During Cycles of Combination Bortezomib, Rituximab, Cyclophosphamide, Doxorubicin, and Prednisone Therapy

Toxicity	Dose Modification or Delay
Hematologic Toxicity	
Grade 3 or higher neutropenia or a platelet count below 25 × 10^9/L	Withhold bortezomib therapy for up to 2 weeks until the patient has an ANC at or above 0.75 × 10^9/L and a platelet count at or above 25 × 10^9/L. • If the toxicity does not resolve after bortezomib has been withheld, discontinue bortezomib. • If toxicity resolves such that the patient has an ANC at or above 0.75 × 10^9/L and a platelet count at or above 25 × 10^9/L, bortezomib dose should be reduced by 1 dose level (from 1.3 mg/M^2 to 1 mg/M^2, or from 1 mg/M^2 to 0.7 mg/M^2).
Grade 3 or higher nonhematologic toxicities	Withhold bortezomib therapy until symptoms of the toxicity have resolved to Grade 2 or better. Bortezomib may then be re-initiated with 1 dose-level reduction (from 1.3 mg/M^2 to 1 mg/M^2, or from 1 mg/M^2 to 0.7 mg/M^2). For bortezomib-related neuropathic pain and/or peripheral neuropathy, hold or modify bortezomib as outlined in the chart for dose modification for bortezomib-related neuropathic pain and/or peripheral neuropathy.

For information concerning rituximab, cyclophosphamide, doxorubicin, and prednisone, see manufacturer’s prescribing information.

Relapsed multiple myeloma and relapsed mantle cell lymphoma:

Withhold dose if a Grade 3 nonhematologic toxicity (e.g., 6 to 10 emeses/24 hr, severe infection) or a Grade 4 hematologic toxicity (e.g., thrombocytopenia less than 25,000/mm^3) occurs. When symptoms have resolved, resume treatment with a dose reduced by 25% (1.3 mg/M^2/dose reduced to 1 mg/M^2/dose, 1 mg/M^2/dose reduced to 0.7 mg/M^2/dose). ■ See doxorubicin monograph for additional dose adjustments required in Doxil and bortezomib combination therapy for treatment of multiple myeloma. ■ Reduce dose in patients who develop bortezomib-related neuropathic pain and/or peripheral sensory or motor neuropathy according to the following chart.

Recommended Dose Modification for Bortezomib-Related Neuropathic Pain and/or Peripheral Sensory or Motor Neuropathy	
Severity of Peripheral Neuropathy Signs and Symptoms[a]	**Modification of Dose and Regimen**
Grade 1 (asymptomatic; loss of deep tendon reflexes or paresthesias) without pain or loss of function	No action.
Grade 1 with pain or Grade 2 (moderate symptoms; limiting instrumental Activities of Daily Living [ADL])[b]	Reduce dose to 1 mg/M^2.
Grade 2 with pain or Grade 3 (severe toxicity symptoms; limiting self-care ADL[c])	Withhold therapy until toxicity resolves. When toxicity resolves, re-initiate with a reduced dose of 0.7 mg/M^2 and change treatment schedule to once per week.
Grade 4 (life-threatening consequences; urgent intervention indicated)	Discontinue bortezomib.

[a] Graded according to Common Terminology Criteria for Adverse Events (CTCAE), v. 4.0.

[b] Instrumental ADL (e.g., preparing meals, shopping for groceries or clothes, using telephone, managing money).

[c] Self-care ADL (e.g., bathing, dressing and undressing, feeding self, using the toilet, taking medications, and not bedridden).

DILUTION

Specific techniques required; see Precautions.

For IV use, reconstitute each 3.5-mg vial **only with 3.5 mL NS.** Concentration equals 1 mg/mL. *The SC route uses less diluent and results in a different concentration (2.5 mg/mL).* To prevent overdosage, use caution when diluting and calculating volume to administer. Manufacturer supplies a sticker that specifies indicated route of administration. Place sticker on syringe of prepared bortezomib.

Storage:

Stable until expiration date when stored at CRT in original package and protected from light. Reconstituted solution stable at 25° C (77° F) for up to 8 hours in a syringe or in original vial when exposed to normal indoor lighting. Must be given within 8 hours.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV bolus injection over 3 to 5 seconds. May be given into a peripheral vein. To ensure the full dose is administered, flush with NS after injection.

May also be given through an IV port if the primary IV is temporarily discontinued. Flush with NS before and after administration.

ACTIONS

A reversible inhibitor of the 26S proteasome, which is a large protein complex that degrades ubiquitinated proteins. The blocking of this proteasome disrupts numerous biologic pathways related to the growth and survival of cancer cells and can lead to cell death. Distributes widely to peripheral tissues. Over 80% is bound to plasma proteins. Mean elimination half-life after multiple doses ranges from 76 to 108 hours after the 1.3 mg/M^2 dose. Metabolized in the liver via selected cytochrome P_{450} enzymes. Pathways of elimination in humans have not been determined.

INDICATIONS

Treatment of patients with multiple myeloma. ■ Treatment of patients with mantle cell lymphoma.

Unlabeled use:

Treatment of multiple myeloma in combination with doxorubicin liposomal injection in patients who have received one prior therapy but have not previously received bortezomib.

CONTRAINDICATIONS

Hypersensitivity to bortezomib or any component of the formulation (e.g., boron or mannitol), not including local reactions. ■ Intrathecal administration.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Velcade may be given IV or SC depending on dilution. Generic formulations of bortezomib are for IV use only. ■ Administered by or under the supervision of a physician experienced in the use of antineoplastic therapy in a facility equipped to monitor the patient and respond to any medical emergency. ■ Bortezomib therapy causes peripheral neuropathy. Both sensory and motor peripheral neuropathy have been reported. Use caution in patients with pre-existing peripheral neuropathy; symptoms may worsen. Many have been treated previously with neurotoxic agents. Incidence of peripheral neuropathy may be less with SC administration. Use of the SC route may be considered for patients who have pre-existing or are at high risk for peripheral neuropathy. ■ May cause orthostatic/postural hypotension. Use with caution in patients with a history of syncope, in patients receiving concomitant medications that may cause hypotension, and in patients who are dehydrated. ■ Hypersensitivity reactions (including anaphylactic reactions) have been reported. ■ Thrombocytopenia and neutropenia have been reported; see Monitor. ■ Gastrointestinal and intracerebral hemorrhages have occurred during thrombocytopenia in association with bortezomib. ■ Acute development or exacerbation of CHF and/or new onset of decreased left ventricular ejection fraction has been reported. ■ Acute respiratory distress syndrome (ARDS) and acute diffuse infiltrative pulmonary disease of unknown etiology such as pneumonitis, interstitial pneumonia, lung infiltration have occurred. ■ Pulmonary hypertension in the absence of left heart failure or significant pulmonary disease has been reported. ■ Posterior reversible encephalopathy syndrome (PRES), formerly termed reversible posterior leukoencephalopathy syndrome (RPLS), has occurred. Patients may present with visual or neurologic disturbances. MRI may be used to confirm diagnosis. ■ Use caution in patients with moderate to severe liver impairment. Clearance decreased; see Monitor and Dose Adjustments. ■ Use caution in patients who are receiving multiple concomitant medications and/or who have serious underlying medical conditions; asymptomatic increases in liver enzymes, hyperbilirubinemia, hepatitis, and rare cases of acute liver failure have been reported. May be reversible if bortezomib is discontinued. Information on rechallenging these patients is limited. ■ Tumor lysis syndrome has been reported; patients with a high tumor burden are at increased risk. ■ Cases, sometimes fatal, of thrombotic microangiopathy, including thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS), have been reported. ■ GI adverse events, including constipation, diarrhea, ileus, nausea, and vomiting, have been reported and may require treatment. ■ Consider antiviral prophylaxis. Herpes simplex and herpes zoster reactivation have been reported.

Monitor:

Obtain baseline CBC with differential and platelet count; repeat before each cycle and monitor as needed during treatment. Monitor platelet count before each dose. ■ Obtain baseline electrolytes, including serum calcium and potassium. Monitor fluid and electrolyte balance and replace as indicated. Prevent dehydration. ■ Obtain baseline bilirubin and AST and repeat as indicated; see Dose Adjustments. Monitor patients with impaired liver function closely for S/S of bortezomib toxicity. ■ Monitor BP closely. Dehydration and/or concomitant medications may contribute to hypotension. Assist with ambulation. ■ Monitor patients at risk for or with existing heart disease closely for S/S of CHF (e.g., exertional dyspnea, orthopnea, edema, tachycardia, pulmonary rales, a third heart sound, jugular venous distention) and/or for new onset of decreased left ventricular ejection fraction. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Antidiarrheal medication (e.g., loperamide [Imodium]) may be indicated. ■ Monitor for S/S of peripheral neuropathy (e.g., burning sensation, discomfort, hyperesthesia [sensitivity of skin], hypoesthesia [impairment of any sense, especially touch], neuropathic pain or weakness, paresthesia [abnormal sensation such as burning, prickling]). Incidence may be increased in patients treated previously with neurotoxic agents (e.g., cisplatin, thalidomide [Thalomid], vinca alkaloids [e.g., vincristine]). See Dose Adjustments; may require change of dose or schedule. Improvement in or a resolution of peripheral neuropathy has been reported following dose adjustment or discontinuation of bortezomib. ■ Monitor for neutropenia and thrombocytopenia (platelet count less than 50,000/mm^3). Occurs in a cyclical pattern with nadirs occurring after the last dose of each cycle and typically recovering before initiation of the next cycle. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor uric acid levels before and during therapy. Hydration and uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may be indicated for serious tumor lysis syndrome. ■ Monitor for S/S of TTP/HUS (e.g., fever, microangiopathic hemolytic anemia [see schistocytes in a blood smear], renal failure, thrombocytopenia, and neurologic manifestations). ■ Hypoglycemia and hyperglycemia have been reported in patients taking oral diabetic agents. Monitor blood glucose levels and adjust antidiabetic medications as indicated; see Drug/Lab Interactions. ■ Monitor respiratory status closely. Any change in condition should be evaluated promptly and treated as indicated. ■ Monitor for S/S associated with development of PRES (e.g., blindness, confusion, headache, hypertension, lethargy, seizures, and other visual and neurologic disturbances).

Patient Education:

Verify pregnancy status of females of reproductive potential before initiating therapy. ■ Avoid pregnancy. Females of reproductive potential should use effective contraception during treatment with bortezomib and for 7 months after treatment. Males with female sexual partners of reproductive potential should use effective contraception during treatment with bortezomib and for 4 months after treatment. Should pregnancy occur, notify physician immediately and discuss potential hazards. ■ May have an effect on male and female fertility. ■ May cause dizziness, fatigue, hypotension, or syncope; use caution when driving or operating machinery. ■ Review all medications with your physician and/or pharmacist; effects of medications for high blood pressure and other medications that may lower blood pressure may increase hypotension. Other agents may increase peripheral neuropathy. May interfere with medications for diabetes. ■ Promptly report bleeding, constipation, decreased appetite, fever, or an increase in blood pressure ■ Review of monitoring requirements and adverse events before therapy is imperative. ■ Avoid dehydration; promptly report diarrhea, dizziness, fainting spells, light-headedness, muscle cramps, and vomiting. ■ Promptly report any signs of infection (e.g., chills, fever, night sweats) or signs of bleeding (e.g., bruising, tarry stools, blood in urine, pinpoint red spots on skin). ■ Promptly report symptoms of peripheral neuropathy (e.g., burning sensation [feet or hands], numbness, pain, tingling, or weakness in the arms or legs). If these symptoms pre-existed, report if they seem to be worse. ■ Promptly report shortness of breath, cough, or other lung problems. ■ Promptly report swelling of the ankles, feet, or legs. ■ Report any visual or neurologic disturbances. ■ Promptly report jaundice or right upper quadrant pain. ■ Promptly report rash, severe injection site reactions, or skin pain. ■ See Appendix D, p. 1311.

Maternal/Child:

Based on the mechanism of action and findings in animals, bortezomib can cause fetal harm. Use of effective contraception required. ■ Discontinue breast-feeding during treatment and for up to 2 months after treatment. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar to other age-groups; however, greater sensitivity in the elderly cannot be ruled out. In clinical trials, patients over 65 years of age had a slightly increased incidence of Grade 3 or 4 toxicity.

DRUG/LAB INTERACTIONS

Drug interaction studies are limited. ■ Bortezomib is a substrate of CYP3A4, 2C19, and

1A2; concomitant administration of **inhibitors or inducers of selected cytochrome P_{450} enzymes** may cause toxicity or reduce effectiveness of bortezomib. Consult pharmacist. **Inhibitors** may reduce metabolism and increase serum levels of bortezomib. ■ Coadministration with **ketoconazole**, an inhibitor, increases bortezomib exposure. Monitor for toxicity. Other examples of **inhibitors** include cimetidine, erythromycins, grapefruit juice, antifungal agents (e.g., itraconazole), nefazodone, and ritonavir. Patients receiving bortezomib in conjunction with a strong CYP3A4 inhibitor should be closely monitored. ■ **Inducers** may increase metabolism and decrease serum levels and effectiveness of bortezomib. Examples of **inducers** may include carbamazepine, phenobarbital, phenytoin, and rifampin. Concomitant use of **strong CYP3A4 inducers** (e.g., rifampin) is not recommended. ■ Hypotension may be increased by **agents that induce hypotension** (e.g., alcohol, antihypertensives [e.g., ACE inhibitors (e.g., lisinopril)], beta-blockers [e.g., atenolol]). ■ May increase or decrease the effects of **oral antidiabetic agents** (e.g., glyburide, glipizide). Monitor blood glucose levels and adjust dose of antidiabetic medication as indicated.

SIDE EFFECTS

Diarrhea, fatigue, peripheral neuropathy, excessive vomiting, and thrombocytopenia may be dose limiting. Most common side effects reported include anemia, anorexia, constipation, diarrhea, fatigue, fever, leukopenia, lymphopenia, nausea and vomiting, neuralgia, neutropenia, peripheral neuropathy, rash, and thrombocytopenia. Abdominal distention, abdominal pain, alopecia, arthralgia, asthenia, bronchitis, cardiac failure, chills, cough, decreased appetite, dehydration, dizziness, dysesthesia, edema, febrile neutropenia, headache, hypertension, hypoesthesia, hypotension, hyperglycemia, malaise, nasopharyngitis, paresthesia, peripheral edema, pneumonia, psychotic disorders (e.g., anxiety, agitation, confusion, insomnia, mental status change, suicidal ideation), reactivation of herpesvirus infections (zoster and simplex), respiratory tract infections, stomatitis, upper abdominal pain, weakness, and weight loss have also been reported. Numerous other side effects have been reported that may or may not be related to bortezomib and include hypersensitivity reactions (including anaphylaxis and immune complex–mediated hypersensitivity), ARDS and other pulmonary disorders, bleeding (e.g., GI, intracerebral), CVA, GI disorders (serious [e.g., acute pancreatitis, ischemic colitis, paralytic ileus]), hepatic disorders (e.g., cholestasis, liver failure, portal vein thrombosis), hyperbilirubinemia, hypernatremia, hyperuricemia, hypocalcemia, hypokalemia, hyponatremia, infections (e.g., aspergillosis, bacteremia, herpes, listeriosis, oral candidiasis, septic shock, toxoplasmosis, URI), MI, pleural effusion, PRES, pulmonary embolism, pulmonary hypertension, renal disorders (e.g., acute or chronic renal failure, calculus, hemorrhagic cystitis, hydronephrosis), respiratory distress, and tumor lysis syndrome. See prescribing information for additional side effects.

Post-Marketing:

Acute diffuse infiltrative pulmonary disease, acute febrile neutrophilic dermatosis (Sweet’s syndrome), blindness, cardiac tamponade, chalazion/blepharitis, deafness (bilateral), herpes meningoencephalitis, ischemic colitis, ophthalmic herpes, optic neuropathy, PRES, progressive multifocal leukoencephalopathy (PML), and Stevens-

Johnson syndrome/toxic epidermal necrolysis.

Overdose:

Profound progressive hypotension, tachycardia, and decreased cardiac contractility. Symptomatic hypotension and thrombocytopenia with fatal outcomes have been reported in patients who received more than twice the recommended dose.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. See Dose Adjustments for dosing modifications based on toxicity. Temporarily discontinue bortezomib if severe thrombocytopenia occurs (less than 25,000 or 30,000/mm^3, depending on indication); may be resumed at a reduced dose after thrombocytopenia is resolved. Severe thrombocytopenia may require platelet transfusions. Reduce dose, withhold dose, or discontinue based on S/S of peripheral neuropathy. Symptoms of peripheral neuropathy may improve or return to baseline if bortezomib is discontinued. Hypotension may respond to adjustment of antihypertensive medications, hydration, or administration of mineralocorticoids and/or sympathomimetics. Withhold bortezomib for Grade 3 neutropenia. Recovery from neutropenia may be spontaneous or may be treated with filgrastim (Neupogen, Zarxio) or pegfilgrastim (Neulasta). Treat anemia as indicated with whole blood products (e.g., packed RBCs) or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen]). For new or worsening cardiopulmonary symptoms, consider interrupting bortezomib until a prompt and comprehensive diagnostic evaluation is conducted. For symptoms of serious liver dysfunction, interrupt bortezomib to assess reversibility. Discontinue bortezomib in patients who develop PRES. In overdose, monitor V/S continuously and provide supportive care. Maintain BP with dopamine, epinephrine, or norepinephrine (Levophed) as needed. Maintain body temperature. If diagnosis of TTP/HUS is suspected, stop treatment and evaluate. If diagnosis is excluded, consider restarting There is no specific antidote; supportive therapy will help sustain the patient in toxicity. Resuscitate as indicated.

BOTULISM IMMUNE GLOBULIN (INTRAVENOUS HUMAN)

(**BOT**-yoo-lism im-**MYOUN** **GLOB**-you-lin, in-tra-**VEE**-nus **HU**-man)
BabyBIG
Immunizing agent (passive)

Available from the California Department of Health Services.

PEDIATRIC DOSE

Pretreatment:

Baseline studies required; see Monitor.

Infants under 1 year of age:

1 mL/kg (50 mg/kg) as a single-dose IV infusion. Administer as soon as the diagnosis of infant botulism is made. See Maternal/Child.

DILUTION

Calculate the number of vials required for the desired dose. Each single-dose vial contains 100 mg. A 10-kg infant would require 500 mg (50 mg/kg × 10 kg = 500 mg, or 5 vials). Reconstitute the lyophilized powder with 2 mL of SWFI provided by the manufacturer to provide a 50 mg/mL solution. A transfer needle or large syringe may be used to add the SWFI. If a transfer needle is used, insert one end into the vial of SWFI first. Supplied in an evacuated vial; the SWFI should transfer by suction. Direct the stream of SWFI toward the side of the vial. To hasten the dissolution, release the residual vacuum after the water is transferred into the evacuated vial. Rotate the vial gently to wet all the powder. ***Do not shake.*** Allow approximately 30 minutes for dissolution. Solution should be clear, colorless, and free of particulate matter. Further dilution is not required.

Storage:

Store lyophilized product between 2° and 8° C (35.6° and 46.4° F). Infusion should begin within 2 hours of reconstitution and should be completed within 4 hours of reconstitution.

Filter:

Use of an in-line or syringe-tip, sterile, disposable filter (18 micron) is recommended.

COMPATIBILITY

Manufacturer recommends administration through a separate IV line without admixture with other drugs. May be “piggybacked” into a pre-existing line if the line contains either NS or one of the following dextrose solutions (with or without NaCl added): D2½W, D5W, D10W, or D20W. If a pre-existing line must be used, botulism immune globulin should not be diluted more than 1:2 with any of the previously named solutions.

RATE OF ADMINISTRATION

Administer intravenously using a low-volume tubing (e.g., 60 gtts/mL) and a constant infusion pump. An in-line or syringe-tip, sterile, disposable filter (18 micron) is recommended. Begin infusion at 0.5 mL/kg/hr (25 mg/kg/hr). If no untoward reactions after 15 minutes, the rate may be increased to 1 mL/kg/hr (50 mg/kg/hr) for the remainder of the infusion. ***Do not exceed this rate.*** Reduce rate at onset of patient discomfort, any minor side effects (e.g., flushing), or other adverse reactions. Discontinue for significant hypotension or S/S of hypersensitivity. At the recommended rate, the infusion should be completed after 67.5 minutes. See Precautions.

ACTIONS

A specialty immunoglobulin (IgG) containing neutralizing antibodies to botulinum toxin types A and B. Should provide the relevant antibodies at levels sufficient to neutralize the expected levels of circulating neurotoxins in infants who may have been exposed to botulinum toxin types A or B. Pooled from adult human plasma specimens selected for their high titers of neutralizing antibody against botulinum neurotoxins type A and B. Purified and standardized by several specific methods (e.g., solvent-detergent viral inactivation process decreases the possibility of transmission of blood-borne pathogens [e.g., HIV, hepatitis]). Half-life is approximately 28 days. Should provide a protective level of neutralizing antibodies for 6 months.

INDICATIONS AND USES

Treatment of infants less than 1 year of age with infant botulism caused by toxin type A or B. Has been shown to decrease the average length of hospital and ICU stay, the average length of time on a mechanical ventilator, and the average number of weeks tube feeding is required in patients with infant botulism.

CONTRAINDICATIONS

Patients with a prior history of severe reaction to other human immunoglobulin preparations or any component of the formulation. Patients with selective immunoglobulin A deficiency have the potential to develop antibodies to immunoglobulin A and could have anaphylactic reactions to subsequent administration of blood products that contain immunoglobulin A.

PRECAUTIONS

IGIV products have been associated with renal dysfunction, acute renal failure, osmotic nephrosis, and death. IGIV products that contain sucrose as a stabilizer have demonstrated an increased risk of renal dysfunction. Botulism immune globulin contains sucrose as a stabilizer. Use extreme caution in patients with any degree of renal insufficiency or in patients who may be predisposed to acute renal failure. Predisposed patients may include patients with diabetes mellitus, paraproteinemia, sepsis, or volume depletion and/or patients receiving known nephrotoxic drugs. Consider benefit versus risk before use. Use of the minimum concentration available and the minimum rate of infusion is recommended. ■ May cause aseptic meningitis syndrome (AMS). May begin from 2 hours to 2 days after treatment. Symptoms are drowsiness, fever, headache (severe), nausea and vomiting, nuchal rigidity, painful eye movements, and photophobia. CSF studies may be positive with pleocytosis and elevated protein levels. Other causes of meningitis must be ruled out. AMS usually resolves with discontinuation of therapy. ■ With the use of botulism immune globulin, as with all plasma products, there is a slight possibility for transmission of blood-borne viral agents and, theoretically, the Creutzfeldt-Jakob disease agent. Risk is reduced by screening donors and various manufacturing processes such as viral inactivation. Risk of transmission versus benefit of treatment must be assessed for each patient.

Monitor:

Obtain a baseline SCr and BUN. ■ Assess infant’s volume status prior to initiating treatment. Patients must not be volume depleted. ■ Monitor vital signs and observe patient continuously during infusion. ■ Acute systemic hypersensitivity reactions were not observed in clinical trials but are possible. Epinephrine and emergency equipment should be readily available. ■ Monitor renal function (e.g., BUN, SCr) and urine output as indicated in infants at increased risk for renal failure.

Patient Education:

Inform parents of possible side effects. ■ Review possible alteration of immunization schedule.

Maternal/Child:

Not indicated for adult patients. ■ Safety and effectiveness for use in pediatric patients over 1 year of age not established.

Elderly:

Not indicated for adult patients.

DRUG/LAB INTERACTIONS

May interfere with immune response to **live virus vaccines** (e.g., polio, measles, mumps, rubella). Defer vaccination with live virus vaccines until approximately 5 months after administration of botulism immune globulin. If such vaccinations were given shortly before or after administration of botulism immune globulin, a revaccination may be necessary.

SIDE EFFECTS

Many of the adverse events observed in studies are part of the known pathophysiology of infant botulism. The most common side effect was a mild, transient, erythematous rash of the face or trunk. Other frequent side effects included back pain, chills, fever, muscle cramps, nausea, rash, vomiting, and wheezing. Other reported reactions included abdominal distention, agitation, anemia, atelectasis, body temperature decrease, convulsions, cough, dehydration, dysphagia, edema, hypertension, hyponatremia, hypotension, injection site reaction, irritability, metabolic acidosis, nasal congestion, neurogenic bladder, oral candidiasis, otitis media, pneumonia, rales, respiratory arrest, rhonchi, stridor, tachycardia, tachypnea, urinary tract infections. Possible reactions not yet reported with botulism immune globulin but reported with other IGIV products include anaphylaxis, angioneurotic edema, renal toxicity (e.g., increased SCr and BUN, acute renal failure, acute tubular necrosis, proximal tubular nephropathy, osmotic nephrosis), and volume overload.

ANTIDOTE

Reduce rate of infusion for patient discomfort or any sign of adverse reaction and in patients at risk for renal insufficiency. Discontinue the drug immediately for any signs of hypersensitivity reaction or renal insufficiency. Notify the physician. Treat anaphylaxis immediately. Epinephrine (Adrenalin), diphenhydramine (Benadryl), oxygen, vasopressors (e.g., dopamine), corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

BRENTUXIMAB VEDOTIN BBW

(bren-**TUX**-i-mab ve-**DOE**-tin)
Adcetris
Antineoplastic
(monoclonal antibody)
pH 6.6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

For dosing instructions of combination agents administered with brentuximab vedotin, see the Clinical Studies section of brentuximab prescribing information and the manufacturer’s prescribing information for the different agents.

Recommended Brentuximab Dosage (Table 1)

Indication	Recommended Dose[a]	Administration	Frequency and Duration
Previously untreated Stage III or IV classical Hodgkin lymphoma	1.2 mg/kg up to a maximum of 120 mg in combination with chemotherapy	IV infusion over 30 minutes	Administer every 2 weeks until a maximum of 12 doses, disease progression, or unacceptable toxicity.
Classical Hodgkin lymphoma consolidation	1.8 mg/kg up to a maximum of 180 mg	IV infusion over 30 minutes	Initiate brentuximab treatment within 4 to 6 weeks post–auto-HSCT or on recovery from auto-HSCT.
			Administer every 3 weeks until a maximum of 16 cycles, disease progression, or unacceptable toxicity.
Relapsed classical Hodgkin lymphoma	1.8 mg/kg up to a maximum of 180 mg	IV infusion over 30 minutes	Administer every 3 weeks until disease progression or unacceptable toxicity.
Previously untreated systemic anaplastic large-cell lymphoma (ALCL) or other CD30-expressing peripheral T-cell lymphomas	1.8 mg/kg up to a maximum of 180 mg in combination with chemotherapy	IV infusion over 30 minutes	Administer every 3 weeks with each cycle of chemotherapy for 6 to 8 doses.
Relapsed primary cutaneous ALCL or CD30-expressing *Mycosis fungoides*	1.8 mg/kg up to a maximum of 180 mg	IV infusion over 30 minutes	Administer every 3 weeks until a maximum of 16 cycles, disease progression, or unacceptable toxicity.
Relapsed systemic ALCL	1.8 mg/kg up to a maximum of 180 mg	IV infusion over 30 minutes	Administer every 3 weeks until disease progression or unacceptable toxicity.

HSCT, Hematopoietic stem cell transplantation.

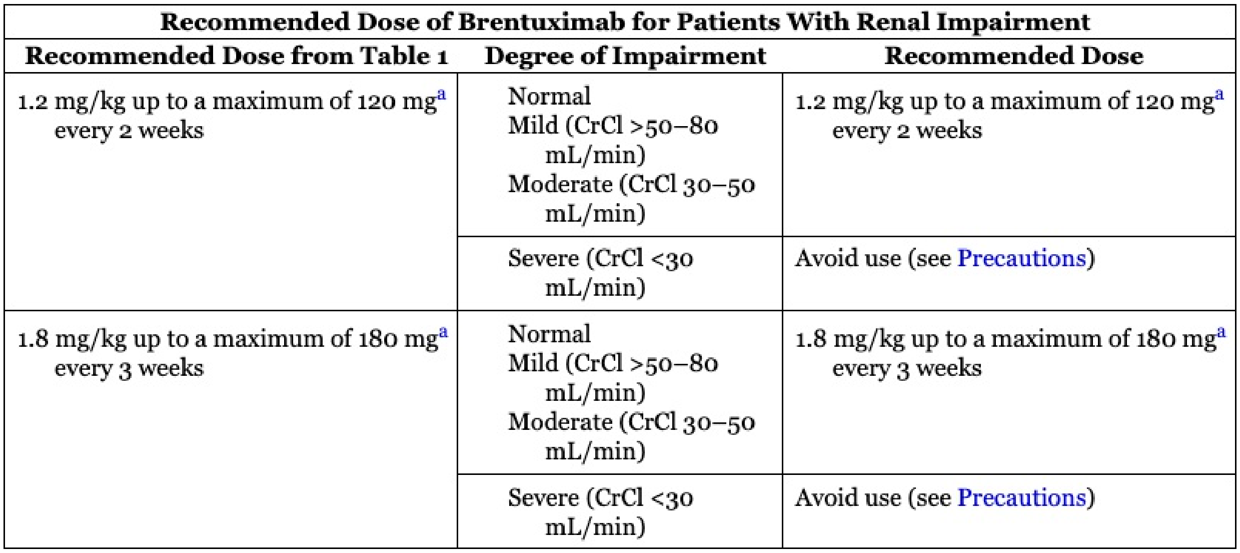
[a] For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg (i.e., dose should not exceed 180 mg).

Prophylactic medication:

In ***patients with previously untreated Stage III or IV classical Hodgkin lymphoma (cHL)*** who are treated with brentuximab plus dacarbazine, doxorubicin, and vinblastine, administer G-CSF beginning with Cycle 1.

In ***patients with previously untreated PTCL who are treated with brentuximab plus cyclophosphamide, doxorubicin, and prednisone,*** administer G-CSF beginning with Cycle 1.

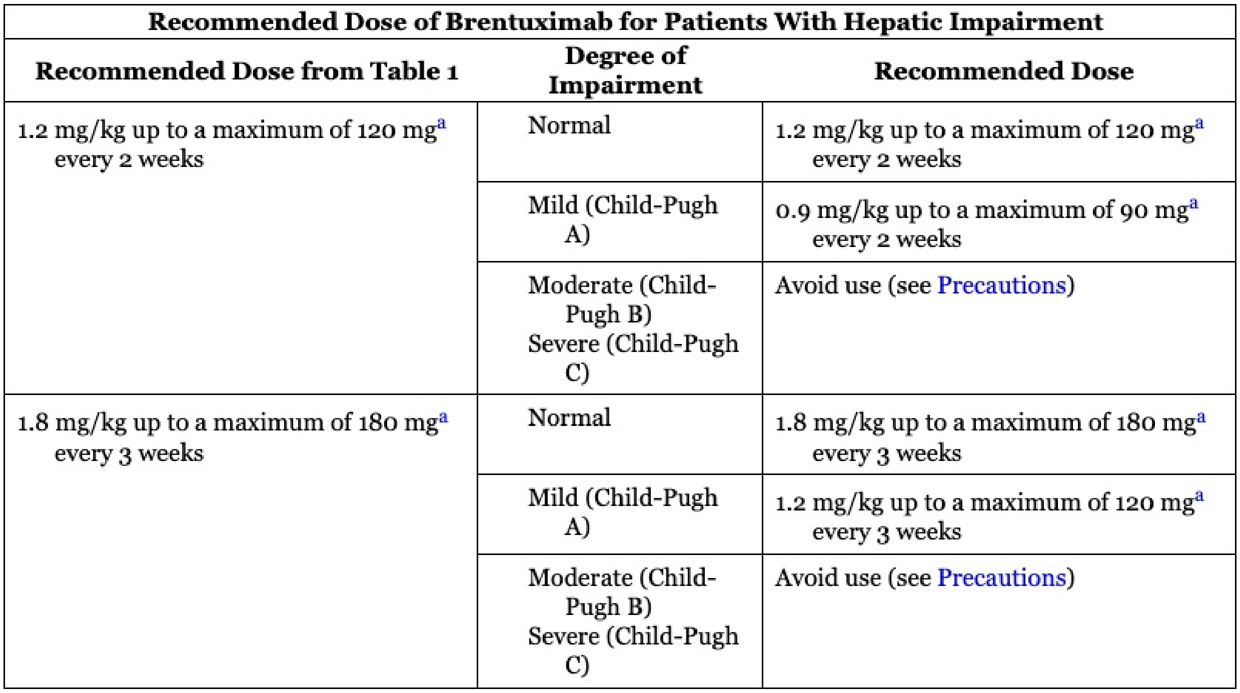
DOSE ADJUSTMENTS



Recommended Dose of Brentuximab for Patients With Renal Impairment

Recommended Dose from Table 1	Degree of Impairment	Recommended Dose
1.2 mg/kg up to a maximum of 120 mg[a] every 2 weeks	Normal Mild (CrCl >50–80 mL/min) Moderate (CrCl 30–50 mL/min)	1.2 mg/kg up to a maximum of 120 mg[a] every 2 weeks
	Severe (CrCl <30 mL/min)	Avoid use (see Precautions)
1.8 mg/kg up to a maximum of 180 mg[a] every 3 weeks	Normal Mild (CrCl >50–80 mL/min) Moderate (CrCl 30–50 mL/min)	1.8 mg/kg up to a maximum of 180 mg[a] every 3 weeks
	Severe (CrCl <30 mL/min)	Avoid use (see Precautions)

[a] For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg.



Recommended Dose of Brentuximab for Patients With Hepatic Impairment

Recommended Dose from Table 1	Degree of Impairment	Recommended Dose
1.2 mg/kg up to a maximum of 120 mg[a] every 2 weeks	Normal	1.2 mg/kg up to a maximum of 120 mg[a] every 2 weeks
	Mild (Child-Pugh A)	0.9 mg/kg up to a maximum of 90 mg[a] every 2 weeks
	Moderate (Child-Pugh B) Severe (Child-Pugh C)	Avoid use (see Precautions)
1.8 mg/kg up to a maximum of 180 mg[a] every 3 weeks	Normal	1.8 mg/kg up to a maximum of 180 mg[a] every 3 weeks
	Mild (Child-Pugh A)	1.2 mg/kg up to a maximum of 120 mg[a] every 3 weeks
	Moderate (Child-Pugh B) Severe (Child-Pugh C)	Avoid use (see Precautions)

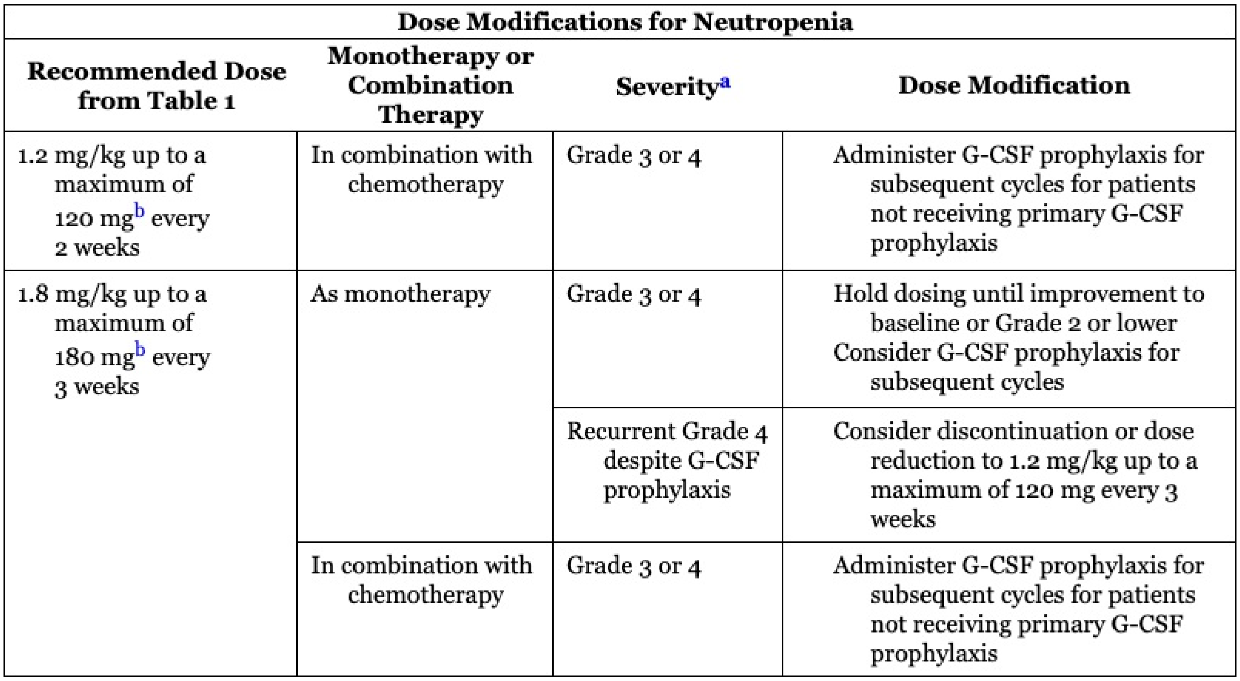
[a] For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg.

Dose Modifications for Peripheral Neuropathy

Recommended Dose from Table 1	Monotherapy or Combination Therapy	Severity[a]	Dose Modification
1.2 mg/kg up to a maximum of 120 mg[b] every 2 weeks	In combination with chemotherapy	Grade 2	Reduce dose to 0.9 mg/kg up to a maximum of 90 mg[b] every 2 weeks
		Grade 3	Hold brentuximab dosing until improvement to Grade 2 or lower Restart at 0.9 mg/kg up to a maximum of 90 mg[b] every 2 weeks Consider modifying the dose of other neurotoxic chemotherapy agents.
		Grade 4	Discontinue brentuximab.
1.8 mg/kg up to a maximum of 180 mg[b] every 3 weeks	As monotherapy	New or worsening Grade 2 or 3	Hold dosing until improvement to baseline or Grade 1 Restart at 1.2 mg/kg up to a maximum of 120 mg[b] every 3 weeks
		Grade 4	Discontinue brentuximab
	In combination with chemotherapy	Grade 2	Sensory neuropathy: Continue treatment at same dose Motor neuropathy: Reduce dose to 1.2 mg/kg up to a maximum of 120 mg every 3 weeks
		Grade 3	Sensory neuropathy: Reduce dose to 1.2 mg/kg up to a maximum of 120 mg every 3 weeks Motor neuropathy: Discontinue dosing
		Grade 4	Discontinue dosing

[a] Events graded using NCI CTCAE Version 3.

[b] For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg.



Dose Modifications for Neutropenia

Recommended Dose from Table 1	Monotherapy or Combination Therapy	Severity[a]	Dose Modification
1.2 mg/kg up to a maximum of 120 mg[b] every 2 weeks	In combination with chemotherapy	Grade 3 or 4	Administer G-CSF prophylaxis for subsequent cycles for patients not receiving primary G-CSF prophylaxis
1.8 mg/kg up to a maximum of 180 mg[b] every 3 weeks	As monotherapy	Grade 3 or 4	Hold dosing until improvement to baseline or Grade 2 or lower Consider G-CSF prophylaxis for subsequent cycles
		Recurrent Grade 4 despite G-CSF prophylaxis	Consider discontinuation or dose reduction to 1.2 mg/kg up to a maximum of 120 mg every 3 weeks
	In combination with chemotherapy	Grade 3 or 4	Administer G-CSF prophylaxis for subsequent cycles for patients not receiving primary G-CSF prophylaxis

[a] Events graded using NCI CTCAE Version 3.

[b] For patients weighing more than 100 kg, base calculated dose on a weight of 100 kg.

DILUTION

Specific techniques required; see Precautions. Each vial contains 50 mg of brentuximab. Calculate the number of vials required. For example, in a 70-kg patient:

1. 1.8 mg/kg × 70 kg =126 mg
2. 126 mg ÷ 50 mg/vial = 2.5+ vials; so 3 vials would be needed

Reconstitute each vial with 10.5 mL of SWFI to yield 5 mg/mL. Direct the stream of diluent toward the side of the vial. Gently swirl to aid dissolution. *Do not shake*. Solution should be clear to slightly opalescent, colorless, and free of visible particulates. Withdraw the calculated dose from the vials (126 mg [from the previous example] ÷ 5 mg/mL = 25.2 mL). This calculated dose must be further diluted in a minimum of 100 mL of NS, D5W, or LR to achieve a final concentration of 0.4 to 1.8 mg/mL. Gently invert to mix the solution.

Filters:

No specific recommendations stated.

Storage:

Refrigerate vials in carton at 2° to 8° C (36° to 46° F) to protect from light. Immediate further dilution of reconstituted vials is preferred; however, they may be refrigerated for up to 24 hours. Do not freeze. Immediate use of fully diluted solution is preferred; however, it may be refrigerated but must be used within 24 hours of reconstitution. Do not freeze. Discard any unused portion left in the vial.

COMPATIBILITY

Manufacturer states, “Do not mix with, or administer as an infusion with, other medicinal products.”

RATE OF ADMINISTRATION

A single dose as an IV infusion equally distributed over 30 minutes.

ACTIONS

A CD30-directed antibody-drug conjugate (ADC). Produced by recombinant DNA technology with three components: (1) the chimeric IgG1 antibody cAC10, specific for human CD30; (2) the microtubule-disrupting agent MMAE; and (3) a protease-cleavable linker that covalently attaches MMAE to cAC10. CD30 is a member of the tumor necrosis factor receptor family. CD30 is expressed on the surface of sALCL (systemic anaplastic large-cell lymphoma) cells and on Hodgkin-Reed-Sternberg (HRS) cells in classical HL, and it has limited expression on healthy tissue and cells. In vitro data suggest that signaling through CD30-CD30L binding may affect cell survival and proliferation. Anticancer activity is thought to result from the binding of the ADC to CD30-expressing cells, followed by internalization of the ADC-CD30 complex and the release of MMAE via proteolytic cleavage. Binding of MMAE to tubulin disrupts the microtubule network within the cell, inducing cell-cycle arrest and apoptotic death of the cells. In addition, in vitro data provide evidence for antibody-dependent cellular phagocytosis. Terminal half-life is approximately 4 to 6 days. Minimal to no accumulation noted with every-3-week dosing. Minimal metabolism of MMAE occurs via oxidation by CYP3A4/5. Moderate amounts excreted as mostly unchanged MMAE in feces and urine.

INDICATIONS AND USES

Treatment of adult patients with previously untreated Stage III or IV classical Hodgkin lymphoma (cHL). Given in combination with dacarbazine, doxorubicin, and vinblastine. ■ Treatment of adult patients with cHL at high risk of relapse or progression as post–autologous hematopoietic stem cell transplantation (auto-HSCT) consolidation or after failure of auto-HSCT or after failure of at least two prior multiagent chemotherapy regimens in patients who are not auto-HSCT candidates. ■ Treatment of adult patients with systemic anaplastic large-cell lymphoma (sALCL) after failure of at least one prior multiagent chemotherapy regimen. ■ Treatment of adult patients with previously untreated sALCL or other CD30-expressing peripheral T-cell lymphomas (PTCL), including angioimmunoblastic T-cell lymphoma and PTCL not otherwise specified. Given in combination with cyclophosphamide, doxorubicin, and prednisone. ■ Treatment of adult patients with relapsed primary cutaneous anaplastic large-cell lymphoma (pcALCL) or CD30-expressing mycosis fungoides who have received prior systemic therapy.

CONTRAINDICATIONS

Concomitant use with bleomycin due to pulmonary toxicity (e.g., interstitial infiltration and/or inflammation); see Drug/Lab Interactions.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ For IV infusion only; do not administer as an IV push or bolus. ■ Usually administered in a setting with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ JC virus infection resulting in progressive multifocal leukoencephalopathy (PML) and death can occur. ■ Causes a peripheral neuropathy that is predominantly sensory and cumulative. Peripheral motor neuropathy has also been reported. ■ Infusion-related reactions, including anaphylaxis, have occurred; see Monitor and Antidote. ■ Prolonged (1 week or longer) severe neutropenia, febrile neutropenia (fatal and serious), and Grade 3 or Grade 4 thrombocytopenia or anemia can occur. G-CSF prophylaxis may be indicated; see Dose Adjustments. Start primary prophylaxis with G-CSF beginning with Cycle 1 for previously untreated patients who received brentuximab vedotin in combination with chemotherapy for Stage III or IV cHL or PTCL. ■ Serious infections and opportunistic infections (e.g., bacteremia, pneumonia, sepsis/septic shock) have been reported. Fatalities have occurred. ■ Risk of tumor lysis syndrome is increased in patients with rapidly proliferating tumor and high tumor burden. ■ Frequency of Grade 3 or higher adverse reactions and deaths was greater in patients with severe renal impairment compared with patients with normal renal function; see Dose Adjustments. ■ Frequency of Grade 3 or higher adverse reactions and deaths was greater in patients with moderate and severe hepatic impairment compared with patients with normal hepatic function; see Dose Adjustments. ■ Serious cases of hepatotoxicity, including fatal outcomes, have been reported. May occur after the first dose or after rechallenge. Pre-existing liver disease, elevated baseline liver enzymes, and concomitant medications may increase the risk of hepatotoxicity. ■ Noninfectious pulmonary toxicity (including acute respiratory distress syndrome [ARDS], interstitial lung disease, and pneumonitis), some with a serious and/or fatal outcome, have been reported. ■ Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN), including serious and/or fatal outcomes, have been reported. ■ Fatal and serious GI complications, including acute pancreatitis, perforation, hemorrhage, erosion, ulcer, intestinal obstruction, enterocolitis, neutropenic colitis, and ileus, have been reported. Lymphoma with pre-existing GI involvement may increase the risk of perforation. ■ Serious events of hyperglycemia, such as new-onset hyperglycemia, exacerbation of pre-existing diabetes mellitus, and ketoacidosis (including fatal outcomes), have been reported. ■ Patients who develop persistently positive antibodies demonstrated a higher incidence of infusion-related reactions. ■ Patients enrolled in the clinical trials for classical HL post–auto-HSCT consolidation received standard infection prophylaxis for herpes simplex virus (HSV), varicella-zoster virus (VZV), and *Pneumocystis jiroveci* pneumonia (PCP) after auto-HSCT.

Monitor:

Obtain baseline CBC and monitor before each dose. Consider more frequent monitoring for patients with Grade 3 or 4 neutropenia. Monitor for fever. If Grade 3 or 4 neutropenia develops, consider dose delays, reductions, discontinuation, or G-CSF prophylaxis with subsequent brentuximab doses; see Dose Adjustments. ■ Obtain baseline and periodic SCr, liver enzymes, and bilirubin. Patients experiencing new, worsening, or recurrent hepatotoxicity may require a delay of therapy, change in dose, or discontinuation of therapy; see Dose Adjustments. ■ Monitor for S/S of neuropathy (e.g., a burning sensation, discomfort, hyperesthesia, hypoesthesia, neuropathic pain, paresthesia, weakness). New or worsening neuropathy may require a delay of therapy, change in dose, or discontinuation of therapy; see Dose Adjustments. ■ Monitor closely during infusion for S/S of hypersensitivity or infusion reactions (e.g., back pain, chills, cough, dyspnea, fever, headache, nausea, pruritus, rash, vomiting). Patients who have experienced a prior infusion-related reaction should be premedicated for subsequent infusions; may include acetaminophen, an antihistamine, and a corticosteroid. Immediately and permanently discontinue brentuximab if anaphylaxis occurs. ■ Monitor for S/S of bacterial, fungal, or viral infections. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for early signs of tumor lysis syndrome (e.g., flank pain and hematuria); monitoring of uric acid levels may be required; maintain hydration. Uric acid–lowering drugs (e.g., allopurinol [Aloprim]) may be indicated. ■ Monitor for S/S of PML (e.g., changes in mood or unusual behavior; confusion; thinking problems; loss of memory; changes in vision, speech, or walking; and decreased strength or weakness on one side of the body); see Antidote. ■ Monitor for S/S of pulmonary toxicity, including cough and dyspnea. ■ Monitor for serious dermatologic reactions. ■ Monitor for GI complications. Prompt diagnostic evaluation and treatment is indicated in patients presenting with new or worsening GI symptoms, including severe abdominal pain. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor serum glucose. If hyperglycemia develops, treat with antihyperglycemic medications as clinically indicated.

Patient Education:

Verify pregnancy status of females of reproductive potential before initiating brentuximab therapy. ■ Avoid pregnancy. Females of reproductive potential should use effective birth control during treatment and for at least 6 months after the final dose of brentuximab. Report a suspected pregnancy immediately. ■ Males with female sexual partners of reproductive potential should use effective contraception during brentuximab treatment and for at least 6 months after the final dose. ■ Male fertility may be compromised by treatment with brentuximab. ■ Promptly report S/S of infection (e.g., chills, cough, fever of 100.5° F or greater, pain with urination). ■ Promptly report S/S of peripheral neuropathy (e.g., muscle weakness, numbness or tingling of the hands or feet). ■ Promptly report S/S of an infusion reaction (e.g., breathing problems, chills, fever, or rash within 24 hours of an infusion). ■ Promptly report changes in mood or unusual behavior; confusion; thinking problems; loss of memory; changes in vision, speech, or walking; and decreased strength or weakness on one side of the body. ■ Promptly report symptoms of pancreatitis or hepatotoxicity (abdominal pain, anorexia, dark urine, fatigue, jaundice). ■ Report symptoms of pulmonary toxicity (e.g., cough or shortness of breath). ■ Report symptoms of GI complications (e.g., severe abdominal pain, diarrhea, nausea, vomiting, chills, fever). ■ See Appendix D.

Maternal/Child:

Avoid pregnancy; can cause fetal harm. Verify pregnancy status of females of reproductive potential before initiating brentuximab therapy; see Patient Education. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether elderly patients respond differently than younger subjects.

DRUG/LAB INTERACTIONS

Concomitant use with **bleomycin** is contraindicated; has resulted in an increased risk of pulmonary toxicity compared with other chemotherapy regimens; see Precautions and Side Effects. ■ In vitro data indicate that monomethyl auristatin E (MMAE) is a substrate and an inhibitor of CYP3A4/5 and a substrate of the efflux transporter P-glycoprotein (P-gp). ■ Coadministration with **ketoconazole** (Nizoral), a potent CYP3A4 inhibitor, increases exposure to MMAE; monitor patients receiving ketoconazole or other potent **CYP3A4 inhibitors** (e.g., clarithromycin [Biaxin], itraconazole [Sporanox], nefazodone, saquinavir [Invirase]) closely for adverse reactions. ■ Coadministration with **rifampin** (Rifadin), a potent CYP3A4 inducer, reduces exposure to MMAE, reducing its effectiveness. ■ Coadministration with **P-gp inhibitors** (e.g., amiodarone [Nexterone], clarithromycin [Biaxin], ritonavir [Norvir], verapamil) may increase exposure to MMAE. Monitor closely for adverse reactions. ■ MMAE does not inhibit other CYP enzymes at relevant clinical concentrations and is not expected to alter the exposure to drugs that are metabolized by CYP3A4 enzymes, including midazolam (Versed).

SIDE EFFECTS

Anemia, constipation, diarrhea, fatigue, fever, nausea, neutropenia, peripheral sensory neuropathy, and vomiting are most common. Neutropenia and peripheral neuropathy can be severe and dose-limiting. Other severe side effects include anaphylaxis and infusion reactions, GI complications, hepatotoxicity, PML, pulmonary toxicity, serious dermatologic reactions (e.g., SJS and TEN), serious infections (including opportunistic infections), and tumor lysis syndrome. Abdominal pain, alopecia, anorexia, anxiety, arthralgia, back pain, chills, cough, decreased appetite, dizziness, dry skin, dyspnea, headache, insomnia, lymphadenopathy, muscle spasms, myalgia, night sweats, oropharyngeal pain, pain, peripheral edema, pruritus, rash, upper respiratory infections, thrombocytopenia, and weight loss have also occurred.

Post-Marketing:

Febrile neutropenia, GI complications (e.g., perforation, hemorrhage, erosion, ulcer, intestinal obstruction, enterocolitis, neutropenic colitis, ileus), hepatotoxicity, hyperglycemia, noninfectious pulmonary toxicity (including ARDS, interstitial lung disease, and pneumonitis), pancreatitis, PML, serious infections (including opportunistic infections), toxic epidermal necrolysis.

ANTIDOTE

Notify physician of all side effects. Treatment of most reactions will be supportive. No known antidote for overdose. Dose delay, dose modification, or discontinuation of therapy may be required in patients with severe or prolonged neutropenia, peripheral neuropathy, or hepatotoxicity. G-CSF prophylaxis may be considered in patients with Grade 3 or Grade 4 neutropenia. If PML is suspected, hold brentuximab. Confirmation of the diagnosis by consultation with a neurologist, brain imaging, CSF testing for JC viral DNA, and/or brain biopsy is indicated. If PML is confirmed, discontinue brentuximab. In the event of new or worsening pulmonary symptoms, hold therapy until evaluation is complete and symptoms have improved. Discontinue if severe dermatologic reaction occurs and treat as indicated. Interrupt the infusion for an infusion-related reaction and institute appropriate medical management. Discontinue the infusion immediately and treat anaphylaxis with oxygen, epinephrine (Adrenalin), antihistamines (e.g., diphenhydramine [Benadryl]), vasopressors (e.g., dopamine), corticosteroids, albuterol, and IV fluids as indicated. Resuscitate as necessary.

BREXANOLONE BBW

(brex-**AN**-oh-lone)
Zulresso
Gamma-aminobutyric acid (GABA) A receptor-positive modulator

USUAL DOSE

Initiate brexanolone treatment early enough in the day to allow for recognition of excessive sedation.

Brexanolone is administered as a 60-hour IV infusion as outlined below:

- 0 to 4 hours: Initiate with a dosage of 30 mcg/kg/hr
- 4 to 24 hours: Increase dosage to 60 mcg/kg/hr
- 24 to 52 hours: Increase dosage to 90 mcg/kg/hr (a reduction in dosage to 60 mcg/kg/hr may be considered during this time period for patients who do not tolerate 90 mcg/kg/hr)
- 52 to 56 hours: Decrease dosage to 60 mcg/kg/hr
- 56 to 60 hours: Decrease dosage to 30 mcg/kg/hr

DOSE ADJUSTMENTS

If excessive sedation occurs at any time during the infusion, stop the infusion until the symptoms resolve. The infusion may be resumed at the same or lower dose as clinically indicated. ■ Dosage adjustment in patients with any degree of hepatic impairment is unnecessary. ■ No dosage adjustment is recommended in patients with mild, moderate, or severe renal impairment. ■ Avoid use in patients with end-stage renal disease (ESRD) with an eGFR of less than 15 mL/min/1.73 M^2 because of the potential accumulation of the solubilizing agent, betadex sulfobutyl ether sodium.

DILUTION

Available as a 100 mg/20 mL (5 mg/1 mL) single-dose vial containing a preservative-free, clear colorless solution. To compound a single infusion bag, withdraw 20 mL of brexanolone from the vial and place in a polyolefin, non-DEHP, nonlatex infusion bag. Immediately dilute with 40 mL of SWFI, and further dilute with 40 mL of NS (total volume of 100 mL) to achieve a final concentration of 1 mg/mL. Administer immediately or refrigerate for later use. The 60-hour infusion will generally require the preparation of five infusion bags. Additional bags will be needed for patients weighing 90 kg or more.

Filters:

Manufacturer states, "Do not use in-line filter infusion sets."

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F) protected from light. ***Do not freeze.*** If the diluted solution is not used immediately, store refrigerated for up to 96 hours. The diluted solution can be used for up to 12 hours of infusion time at RT. Discard any unused solution after 12 hours of infusion.

COMPATIBILITY

Manufacturer states, "Prepare and store in a polyolefin, non-DEHP, nonlatex infusion bag," "Use a PVC, non-DEHP, nonlatex infusion set," and "Administer via a dedicated line. Do not inject other medications into the infusion bag or mix with brexanolone."

RATE OF ADMINISTRATION

Administer via a dedicated line using a PVC, non-DEHP, nonlatex infusion set. Use a programmable peristaltic infusion pump to ensure accurate delivery. Fully prime infusion administration sets with admixture before inserting into the pump and connecting to the venous catheter.

ACTIONS

A neuroactive steroid gamma-aminobutyric acid (GABA) A receptor-positive modulator. The mechanism of action of brexanolone in the treatment of postpartum depression (PPD) is not fully understood but is thought to be related to its positive allosteric modulation of GABA A receptors. Exhibits extensive distribution into tissues. Plasma protein binding is greater than 99%. The terminal half-life is approximately 9 hours. Extensively metabolized by non–CYP-based pathways. Metabolites are pharmacologically inactive. Excreted in feces (primarily as metabolites) and in urine (with less than 1% as unchanged brexanolone). Secreted in breast milk.

INDICATIONS AND USES

Treatment of postpartum depression (PPD) in adults.

CONTRAINDICATIONS

Manufacturer states "None."

PRECAUTIONS

A health care provider must be available on site to continuously monitor the patient, and intervene as necessary, for the duration for the brexanolone infusion. ■ Patients treated with brexanolone are at risk of somnolence, excessive sedation, sudden loss of consciousness, or an altered state of consciousness during administration; see Dose Adjustments. Time to full recovery from loss or altered state of consciousness after dose interruption ranged from 15 to 60 minutes. There was no clear association between loss or alteration of consciousness and pattern or timing of dose. Not all patients who experienced a loss or alteration of consciousness reported sedation or somnolence before the episode. ■ In pooled analyses of placebo-controlled trials of chronically administered antidepressant drugs (SSRIs and other antidepressant classes), the incidence of suicidal thoughts and behaviors in antidepressant-treated patients 24 years of age and younger was greater than in placebo-treated patients. There was considerable variation in the risk of suicidal thoughts and behaviors among drugs, but an increased risk was identified in young patients for most drugs studied. Consider changing the therapeutic regimen, including discontinuing brexanolone, in patients whose depression becomes worse or in patients who experience emergent suicidal thoughts and behaviors. ■ Brexanolone is a Schedule IV controlled substance, with the potential for abuse and dependence. In PPD trials, end of treatment occurred through tapering, so it was not possible to assess whether abrupt discontinuation produced withdrawal symptoms indicative of physical dependence. It is recommended that brexanolone be tapered according to the dosage recommendations unless symptoms warrant immediate discontinuation; see Usual Dose and Dose Adjustments. ■ Brexanolone is available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS) called the ZULRESSO REMS; see manufacturer's prescribing information for requirements.

Monitor:

Monitor for excessive sedation and sudden loss of consciousness. ■ Assess for excessive sedation every 2 hours during planned, nonsleep periods. Immediately stop the infusion if there are S/S of excessive sedation. After symptoms resolve, the infusion may be resumed at the same rate or at a reduced rate as clinically appropriate. ■ Patients must be accompanied during interactions with their child(ren) because of the potential for excessive sedation and sudden loss of consciousness. ■ Monitor for hypoxia using continuous pulse oximetry equipped with an alarm. Immediately stop the infusion if pulse oximetry indicates hypoxia. The infusion should not be resumed. ■ Monitor for worsening depression or suicidal ideation.

Patient Education:

Read the FDA-approved patient labeling (Medication Guide). ■ Avoid pregnancy. In the event of a pregnancy, enrollment in the National Pregnancy Registry for Antidepressants is encouraged. ■ After the infusion, avoid potentially hazardous activities requiring mental alertness, such as driving, until any sedative effects have dissipated. ■ Request assistance during interactions with child(ren) because of the potential for excessive sedation and sudden loss of consciousness. Must not be the primary caregiver. ■ Review all medications with a health care provider; drug interactions are possible. ■ Brexanolone can be abused or lead to dependence. ■ Report signs of excessive sedation that may occur during the infusion (patient and caregiver). ■ Report worsening depression or the emergence of suicidal thoughts and behavior (patient and caregiver). ■ Brexanolone is available only through a restricted program called the ZULRESSO REMS. Patient enrollment and monitoring is required.

Maternal/Child:

Based on animal studies of other drugs that enhance GABAergic inhibition, brexanolone may cause fetal harm when administered to a pregnant woman. Patients exposed to brexanolone during pregnancy are encouraged to enroll in the National Pregnancy Registry for Antidepressants. ■ Present in breast milk, but infant exposure is expected to be low. Consider risk versus benefit for mother and infant. ■ Safety and effectiveness in pediatric patients have not been established.

Elderly:

PPD is a condition associated with pregnancy; there is no geriatric experience with brexanolone.

DRUG/LAB INTERACTIONS

Drug interactions studies have not been conducted. ■ Concomitant use with other CNS depressants (e.g., alcohol, antidepressants, benzodiazepines, opioids) may increase the likelihood or severity of adverse reactions related to sedation. ■ No clinically significant differences in the pharmacokinetics of phenytoin (CYP2C9 substrate) were observed when used concomitantly with brexanolone.

SIDE EFFECTS

The most commonly reported adverse reactions were dry mouth, flushing/hot flush, loss of consciousness, and sedation/somnolence. Adverse reactions leading to treatment discontinuation were sedation-related effects (loss of consciousness, presyncope, syncope, and vertigo) or infusion site pain. Adverse reactions leading to dose reduction or interruption were sedation-related effects (dizziness, fatigue, loss of consciousness, somnolence, syncope), changes in blood pressure, and infusion site events. Other reported adverse events include diarrhea, dyspepsia, oropharyngeal pain, and tachycardia.

Overdose:

May result in excessive sedation, including loss of consciousness and the potential for accompanying respiratory changes.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Immediately stop the infusion for S/S of excessive sedation. After symptoms resolve, the infusion may be resumed at the same or reduced rate as clinically appropriate. Immediately stop the infusion for hypoxia. The infusion should not be resumed. In case of overdose, stop the infusion immediately and initiate supportive measures as necessary. Brexanolone is rapidly cleared from plasma.

BRIVARACETAM

(**BRIV**-a-**RA**-se-tam)
Briviact
Anticonvulsant
pH 5.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

Brivaracetam may be initiated with either IV or oral administration. When initiating treatment, gradual dose escalation is not required. Dose should be based on clinical response and tolerability. IV injection may also be used when oral administration is temporarily not feasible and should be administered at the same dose and frequency as oral brivaracetam. Use of the IV formulation beyond 4 consecutive days of treatment has not been studied.

Patients 16 years of age and older (monotherapy or adjunctive therapy):

50 mg twice daily (100 mg/day) is the recommended starting dose. Based on individual patient tolerability and therapeutic response, the maintenance dose may be adjusted down to a minimum of 25 mg twice daily (50 mg/day) or up to a maximum of 100 mg twice daily (200 mg/day).

DOSE ADJUSTMENTS

See Usual Dose. ■ Recommended starting dose for all stages of hepatic impairment (for patients 16 years of age and older) is 25 mg twice daily (50 mg/day), with a recommended maximum dose of 75 mg twice daily (150 mg/day). ■ For patients receiving concomitant rifampin, increase the dose by up to 100% (i.e., double the dose); see Drug/Lab Interactions. ■ No dose adjustment required for patients with impaired renal function; see Precautions.

DILUTION

A clear, colorless solution available as 50 mg/5 mL (10 mg/mL) in a single-use vial. Withdraw the desired dose. May be administered without further dilution or may be further diluted with NS, D5W, or LR and given as an infusion.

Filters:

Specific information not available.

Storage:

Store at CRT before use. Do not freeze. Diluted solution should not be stored for more than 4 hours at RT; may be stored in polyvinyl chloride (PVC) bags. Discard any unused portion of vial.

COMPATIBILITY

Compatibility information not available from manufacturer. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV injection or infusion over 2 to 15 minutes. Flush IV line before and after injection.

ACTIONS

An antiepileptic (anticonvulsant) drug. The precise mechanism of action is unknown. Displays a high and selective affinity for synaptic vesicle protein 2A (SV2A) in the brain, which may contribute to the anticonvulsant effect. Weakly bound to plasma proteins. Primarily metabolized by hydrolysis and secondarily by hydroxylation. The hydrolysis reaction is mediated by hepatic and extrahepatic amidase. The hydroxylation pathway is mediated primarily by CYP2C19. Terminal plasma half-life is approximately 9 hours. May cross the placental barrier. Eliminated primarily by metabolism and by excretion in urine.

INDICATIONS AND USES

Treatment of partial-onset seizures in patients 16 years of age and older. IV injection may be used when oral administration is temporarily not feasible; see Maternal/Child.

CONTRAINDICATIONS

Known hypersensitivity to brivaracetam or any of its inactive ingredients.

PRECAUTIONS

For IV use only. ■ Antiepileptic drugs (AEDs) increase the risk of suicidal thoughts or behavior in patients taking these drugs for any indication. Patients treated with any AED for any indication should be monitored for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. Some behavioral changes may resolve without intervention. Others may require dose reduction or discontinuation of brivaracetam. ■ Associated with CNS side effects (somnolence, fatigue, dizziness, coordination difficulties [abnormal gait, ataxia, balance disorder, incoordination]). The risk is greatest early in treatment but can occur at any time; see Monitor and Patient Education. ■ Has been associated with behavioral and psychiatric abnormalities (e.g., aggression, agitation, altered mood, anger, anxiety, apathy, belligerence, depression, emotional lability, irritability, mood swings, nervousness, psychomotor hyperactivity, restlessness, tearfulness, and psychotic symptoms, including hallucinations, paranoia, acute psychosis, and suicidal ideation). ■ Hypersensitivity reactions have been reported. ■ Avoid abrupt withdrawal to minimize the risk of increased seizure frequency and status epilepticus. ■ Not recommended for use in patients with end-stage renal disease who are undergoing dialysis; data not available.

Monitor:

Obtain baseline and periodic liver function tests. ■ Monitor for the emergence or worsening of depression, suicidal thoughts or behavior, and/or any unusual changes in mood or behavior. ■ Observe for seizure activity. ■ Observe closely for signs of CNS side effects; see Precautions. ■ Monitor for S/S of a hypersensitivity reaction; angioedema and bronchospasm have been reported. If a reaction occurs, discontinue brivaracetam.

Patient Education:

Review manufacturer’s medication guide. ■ May cause dizziness, coordination difficulties, and somnolence; use caution when performing tasks that require alertness or coordination (e.g., operating machinery, driving). ■ May increase the risk of suicidal thoughts and behavior. Promptly report the emergence or worsening of S/S of depression, any unusual changes in mood or behavior, or thoughts of self-harm. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hypotension, rash, tightness of the chest, urticaria, wheezing). ■ Women who are pregnant or who become pregnant should be encouraged to enroll in the North American Antiepileptic Drug (NAAED) Pregnancy Registry. ■ Do not discontinue without consulting a health care provider. Must be gradually withdrawn to reduce the potential for increased seizure frequency and status epilepticus.

Maternal/Child:

Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. Based on animal studies, may cause fetal harm. ■ Insufficient data on effects during breast-feeding; consider risk versus benefit. ■ The safety of brivaracetam injection in pediatric patients has not been established; however, ***oral*** brivaracetam can be used and is indicated for the treatment of partial-onset seizures in patients 4 years of age and older. See prescribing information. ■ Safety and effectiveness for use in patients 16 years of age and older have been established.

Elderly:

Numbers in clinical studies insufficient to determine if elderly patients respond differently than younger patients. Dose selection should usually start at the low end. Consider decreased hepatic, renal, or cardiac function and concomitant disease or other drug therapy.

DRUG/LAB INTERACTIONS

Coadministration with rifampin decreases brivaracetam plasma concentrations.

Brivaracetam dose should be increased by up to 100% while patients are receiving concomitant treatment with rifampin. ■ Coadministration with carbamazepine may increase exposure to the active metabolite of carbamazepine. Consider carbamazepine dose reduction if tolerability issues arise. ■ Increases plasma concentrations of phenytoin. Monitor phenytoin levels when concomitant brivaracetam is added to or discontinued from ongoing phenytoin therapy. ■ Coadministration of brivaracetam with levetiracetam provided no added therapeutic benefit.

SIDE EFFECTS

Dizziness, fatigue, nausea, sedation, somnolence, and vomiting are most common. Cerebellar coordination and balance disturbances, constipation, decreased neutrophil count, decreased white blood cell count, dysgeusia, euphoric mood, feeling drunk, and infusion site pain and irritability have also been reported. See Precautions.

Overdose:

Anxiety, balance disorder, bradycardia, diplopia, dizziness, fatigue, nausea, somnolence, and vertigo.

ANTIDOTE

Keep physician informed of all side effects. Some may not require intervention, and others may improve with a reduced dose or discontinuation of brivaracetam. Treat hypersensitivity reactions immediately with oxygen, epinephrine, antihistamines, vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Support patient as required in overdose. There is no specific antidote. Ensure adequate airway, oxygenation, and ventilation and monitor vital signs, cardiac rate, and rhythm. Hemodialysis is not expected to enhance clearance. Resuscitate as necessary.

BUMETANIDE BBW

(byou-**MET**-ah-nyd)
Diuretic (loop)
pH 6.8 to 7.8

USUAL DOSE

0.5 to 1 mg. May be repeated at 2- to 3-hour intervals. Do not exceed 10 mg/24 hr. Can be used for patients allergic to furosemide. 1:40 mg ratio (bumetanide to furosemide) is used to determine dose. Individualize dose and schedule; see Precautions/Monitor.

DOSE ADJUSTMENTS

Start at lower end of dosing range in the elderly. Consider decreased cardiac, hepatic, or renal function; concomitant disease; and other drug therapy.

DILUTION

May be given undiluted. Not usually added to IV solutions but **compatible** with D5W, NS, and LR. Usually given through Y-tube or three-way stopcock of infusion set. Use only freshly prepared solutions for infusion. Discard after 24 hours.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose by IV injection over 1 to 2 minutes. Give infusion at prescribed rate.

ACTIONS

A sulfonamide diuretic, antihypertensive, and antihypercalcemic agent related to the thiazides. A loop diuretic agent. Extremely potent. Onset of action is within minutes and duration of action may last 4 to 6 hours. Apparently acts on the proximal and distal ends of the tubule and the ascending limb of the loop of Henle to excrete water, sodium, chloride, and potassium. Will produce diuresis in alkalosis or acidosis. Rapidly distributed, it is excreted primarily in the urine.

INDICATIONS AND USES

Edema associated with congestive heart failure, cirrhosis of the liver with ascites, renal diseases including nephrotic syndrome. ■ Acute pulmonary edema. ■ Edema unresponsive to other diuretic agents. ■ Diuresis in patients allergic to furosemide. ■ Adjunct in combination with other antihypertensive agents in the treatment of hypertensive crisis.

Unlabeled uses:

Treatment of hypercalcemia.

CONTRAINDICATIONS

Anuria, known hypersensitivity to bumetanide. Use caution in patients with hepatic coma or in states of severe electrolyte depletion. Do not use until condition is improved or corrected. See Precautions.

PRECAUTIONS

May be used concurrently with aldosterone antagonists (e.g., spironolactone [Aldactone]) for more effective diuresis and to prevent excessive potassium loss. ■ May increase blood glucose; has precipitated diabetes mellitus. ■ May lower serum calcium level, causing tetany. ■ In rare instances may precipitate an acute attack of gout. ■ Risk of ototoxicity increased with higher doses, rapid injection, decreased renal function, or concurrent use with other ototoxic drugs; see Drug/Lab Interactions. ■ Patients allergic to sulfonamides may have an allergic reaction to bumetanide. ■ Excessive doses can lead to profound diuresis with water and electrolyte depletion.

Monitor:

Monitor for excessive diuresis with water and electrolyte depletion. Routine checks on electrolyte panel, CO_2, serum glucose, uric acid, and BUN are necessary during therapy. Potassium chloride replacement may be required.

Patient Education:

Hypotension may cause dizziness; move slowly, and request assistance to sit on edge of bed or ambulate. ■ May decrease potassium levels and require a supplement.

Maternal/Child:

Category C: use in pregnancy only if clearly needed. ■ Consider discontinuing breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Has been used in infants age 4 days to 6 months at doses ranging from 0.005 mg/kg to 0.1 mg/kg. Maximal diuretic effect seen at doses of 0.035 to 0.04 mg/kg. Elimination half-life decreases during the first month of life from approximately 6 hours at birth to 2.4 hours at 1 month.

Elderly:

Response similar to that seen in younger patients; however, dose selection should be cautious; see Dose Adjustments. Consider increased sensitivity to hypotensive and electrolyte effects and increased risk of circulatory collapse or thromboembolic episodes. ■ Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Causes excessive potassium depletion with **corticosteroids, thiazide diuretics, amphotericin B**. ■ Potentiates **antihypertensive drugs**; reduced dose of the antihypertensive agent or both drugs may be indicated. ■ May cause transient or permanent deafness with doses exceeding the usual or when given in conjunction with **other ototoxic drugs** (e.g., aminoglycosides, cisplatin). ■ **Amphotericin B** may increase potential for ototoxicity and nephrotoxicity; avoid concurrent use. ■ Nephrotoxicity increased by other **nephrotoxic agents** (e.g., acyclovir, aminoglycosides, cyclosporine, vancomycin); avoid concurrent use. ■ May increase serum levels of **lithium** (may cause toxicity). ■ May cause cardiac arrhythmias with **amiodarone or digoxin** (potassium depletion). ■ Risk of cardiotoxicity increased with **pimozide**; concurrent use not recommended. ■ May enhance or inhibit actions of **nondepolarizing muscle relaxants or theophyllines.** ■ May cause hyperglycemia with **insulin or sulfonylureas** by decreasing glucose tolerance. ■ Effects may be inhibited by **ACE inhibitors**, **NSAIDs**, **probenecid, or** in patients with cirrhosis and ascites who are taking **salicylates.** ■ May cause profound diuresis and serious electrolyte abnormalities with **thiazide diuretics** because of synergistic effects. ■ Do not use concomitantly with **ethacrynic acid**; risk of ototoxicity markedly increased. ■ Smoking may increase secretion of ADH-decreasing diuretic effects and cardiac output. ■ See Precautions.

SIDE EFFECTS

Usually occur in prolonged therapy, seriously ill patients, or following large doses.

Abdominal pain, arthritic pain, azotemia, dizziness, ECG changes, elevated SCr, encephalopathy, headache, hyperglycemia, hyperuricemia, hypocalcemia, hypochloremia, hypomagnesemia, hyponatremia, hypotension, impaired hearing, muscle cramps, nausea, pruritus, rash.

Major:

Anaphylactic shock, blood volume reduction, circulatory collapse, dehydration, excessive diuresis, hypokalemia, metabolic acidosis, thrombocytopenia, vascular thrombosis, and embolism.

ANTIDOTE

If minor side effects are noted, discontinue the drug and notify the physician, who may treat the side effects symptomatically and continue the drug. If side effects are progressive or any major side effect occurs, discontinue the drug immediately and notify the physician. Treatment of major side effects is symptomatic and aggressive and includes fluid and electrolyte replacement. Resuscitate as necessary.

BUPRENORPHINE HYDROCHLORIDE BBW

(byou-pren-**OR**-feen hy-droh-**KLOR**-eyed)
Buprenex
Narcotic analgesic (agonist-antagonist)
Anesthesia adjunct
pH 3.5 to 5.5

USUAL DOSE

Individualize dose, taking into account the patient’s severity of pain, response, prior analgesic treatment experience, and risk factors for addiction, abuse, and misuse. Use lowest effective dose for the shortest duration consistent with the patient’s treatment goals.

Pain control (adults and pediatric patients over 12 years of age):

0.3 mg (1 mL). Repeat every 6 hours as necessary. May be repeated in 30 to 60 minutes, if indicated.

PEDIATRIC DOSE

Pain control (2 to 12 years of age):

2 to 6 mcg/kg of body weight/dose every 4 to 6 hours as needed. A repeat dose in 30 to 60 minutes is **not** recommended. Longer intervals (6 to 8 hours) may be sufficient for some patients. Determine appropriate interval through clinical assessment. See Maternal/Child.

DOSE ADJUSTMENTS

Reduce dose in high-risk patients (e.g., elderly or debilitated, respiratory disease), when other CNS depressants have been given, and in the immediate postoperative period; see Drug/Lab Interactions. ■ Reduced dose may be required in impaired liver function.

DILUTION

May be given undiluted.

Filters:

Not required by manufacturer; however, 0.2-micron filters were used during manufacturing. No loss of drug potency expected.

Storage:

Before use, store at CRT. Avoid freezing and/or prolonged exposure to light.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over at least 2 minutes.

ACTIONS

A synthetic narcotic agonist-antagonist analgesic. Buprenorphine is a partial agonist at the mu-opioid receptor and an antagonist at the kappa-opioid receptor. 0.3 mg buprenorphine is approximately equivalent to 10 mg morphine in analgesic and respiratory depressant effects. It demonstrates narcotic antagonist activity and has been shown to be equipotent with naloxone as an antagonist of morphine. Pain relief is effected within minutes and lasts up to 6 hours. Metabolized in the liver. Primarily excreted through feces and to a lesser extent in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Management of pain severe enough to require an opioid analgesic and for which alternate treatments are inadequate.

Limitations of use:

Because of the risk of addiction, abuse, and misuse, even at recommended doses, reserve buprenorphine for use in patients for whom alternative treatment options (e.g., nonopioid analgesics or opioid combination products):

- Have not been tolerated or are not expected to be tolerated.
- Have not provided adequate analgesia or are not expected to provide adequate analgesia.

CONTRAINDICATIONS

Hypersensitivity to buprenorphine (e.g., anaphylaxis) or any other ingredient in the formulation. ■ Significant respiratory depression. ■ Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment. ■ Known or suspected GI obstruction, including paralytic ileus.

PRECAUTIONS

Buprenorphine exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient's risk before prescribing buprenorphine, and monitor all patients regularly for the development of these behaviors and conditions. The potential for these risks should not, however, prevent the prescribing of buprenorphine for the proper management of pain in any given patient. ■ Strategies to reduce the risk of diversion or misuse should be employed by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Serious, life-threatening, or fatal respiratory depression may occur. Respiratory depression may occur at any time, but risk is greatest during initiation of therapy or after a dose increase. To reduce the risk of respiratory depression, proper dosing and titration are essential. Overestimating the buprenorphine dose when converting patients from another opioid product can result in a fatal overdose with the first dose. ■ CO_2 retention from respiratory depression can exacerbate the sedating effects of opioids. ■ Use caution with asthma, COPD, or other chronic pulmonary diseases or with respiratory depression or difficulty from any source; patients are at increased risk for decreased respiratory drive, including apnea, even at recommended doses. ■ Use caution in elderly, cachectic, or debilitated patients; respiratory depression is more likely to occur. Use caution in pediatric patients, elderly or debilitated patients, or patients with severe impairment of renal, hepatic, or pulmonary function; myxedema or hypothyroidism; adrenocortical insufficiency; CNS depression or coma; toxic psychoses; prostatic hypertrophy or urethral stricture; acute alcoholism; delirium tremens; or kyphoscoliosis. ■ Cases of adrenal insufficiency have been reported with opioid use. If adrenal insufficiency is diagnosed, treat with physiologic replacement doses of corticosteroids and wean the patient off the opioid to allow adrenal function to recover. Another opioid may be tried; some cases reported use of a different opioid without recurrence of adrenal insufficiency. ■ Cases of serotonin syndrome have been reported during concomitant use of opioids with serotonergic drugs. ■ Prolongation of the QTc interval has been reported in some patients. Avoid buprenorphine in patients who have a history of long-QT syndrome or an immediate family member with this condition or in patients receiving concurrent treatment with Class IA antiarrhythmic agents (e.g., quinidine, procainamide), Class III antiarrhythmic agents (e.g., amiodarone, sotalol), or other medications that prolong the QT interval. Consider risk in patients with hypokalemia, hypomagnesemia, or clinically unstable cardiac disease (e.g., heart failure, MI, and significant bradycardia). Periodic ECG monitoring is recommended in these patients. ■ May cause severe hypotension, including orthostatic hypotension and syncope, in ambulatory patients. Patients whose ability to maintain BP has already been compromised by a reduced blood volume or concurrent administration of certain CNS depressant drugs (e.g., phenothiazines or general anesthetics) are at increased risk. ■ In patients with circulatory shock, buprenorphine may cause vasodilation and can further reduce cardiac output and BP. Avoid buprenorphine in patients with circulatory shock. ■ Use caution in patients with head injury, brain tumors, or increased intracranial pressure. Respiratory depression may cause increased P_{CO_2}, cerebral vasodilation, and increased intracranial pressure. Clinical course of head injury may be obscured. ■ Cases of acute and chronic hypersensitivity to buprenorphine have been reported. ■ Use caution in patients with biliary tract disease, including acute pancreatitis. May cause spasm of the sphincter of Oddi. Opioids may cause increases in amylase. ■ Buprenorphine may increase the frequency of seizures in patients with seizure disorders. ■ May precipitate withdrawal symptoms if stopped too quickly after prolonged use or if patient has been taking opiates. ■ Tolerance (the need for increasing doses to maintain a defined effect such as analgesia [in the absence of disease progression or other external factors]) can develop with chronic use. ■ See Maternal/Child and Drug/Lab Interactions.

Monitor:

Naloxone, oxygen, and controlled respiratory equipment must be available. ■ Observe patient frequently and monitor vital signs. Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely when initiating or titrating therapy and during ambulation. ■ Monitor patients who may be susceptible to the intracranial effects of CO_2 retention for signs of sedation and respiratory depression. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylactic shock, angioneurotic edema, bronchospasm, hives, pruritus, rash). ■ Monitor patients with biliary tract disease for worsening of symptoms. ■ Monitor patients with a history of seizure disorders for worsening seizure control. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment. ■ Periodic ECG monitoring may be indicated in patients at risk for QT prolongation. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Monitor patients regularly for the development of opioid addiction, abuse, and misuse.

Patient Education:

Review medications with provider. ■ Avoid use of alcohol or other CNS depressants. ■ Promptly report S/S of serotonin syndrome. ■ Use caution performing any task requiring alertness; may cause dizziness, euphoria, and sedation. ■ Request assistance for ambulation. ■ May result in severe constipation. Scheduled bowel regimen recommended. ■ May result in addiction, abuse, and misuse, even when taken as recommended.

Maternal/Child:

Safety for use during pregnancy and labor and delivery not established. Use only when clearly needed. Closely monitor neonates exposed to buprenorphine during labor and delivery for signs of respiratory depression. ■ Prolonged use of buprenorphine during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life-threatening if not recognized and treated. Infants born to mothers receiving buprenorphine during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome if indicated. See literature for treatment protocols. ■ Discontinue breast-feeding. ■ Not recommended in pediatric patients under 2 years of age.

Elderly:

See Dose Adjustments. ■ May be more sensitive to effects (e.g., respiratory depression, urinary retention, constipation, dizziness). ■ Analgesia should be effective with lower doses. ■ Consider possibility of decreased organ function.

DRUG/LAB INTERACTIONS

Concomitant use with benzodiazepines or other CNS depressants (e.g., nonbenzodiazepine sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Use minimum effective dose for the shortest duration possible, and monitor for S/S of respiratory depression and sedation. ■ May decrease analgesic effects of **other narcotics;** avoid concurrent use. ■ Clearance decreased and serum levels increased by **cytochrome P_{450} inhibitors** (e.g., azole antifungal agents, macrolide antibiotics, protease inhibitors). Monitor with concurrent use; dose adjustment may be indicated. ■ Clearance increased and serum levels decreased by **cytochrome P_{450} inducers** (e.g., carbamazepine, phenytoin, rifampin). Use caution; dose adjustments may be indicated. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including buprenorphine, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ Severe and unpredictable potentiation of **MAO inhibitors** (e.g., selegiline, phenelzine, tranylcypromine, linezolid) has been reported. MAO inhibitor interactions may manifest as serotonin syndrome or opioid toxicity (e.g., respiratory depression, coma). Use of buprenorphine is not recommended for patients taking MAOIs or within 14 days of stopping such treatment. ■ **Mixed agonist/antagonist analgesics** (e.g., butorphanol, nalbuphine) may reduce the analgesic effect of buprenorphine and/or precipitate withdrawal symptoms. Avoid concomitant use. ■ Buprenorphine may enhance the neuromuscular blocking action of **skeletal muscle relaxants** (e.g., cyclobenzaprine, orphenadrine), increasing the degree of respiratory depression. Monitor patient and decrease dose if indicated. ■ Opioids can reduce the efficacy of **diuretics** by inducing the release of antidiuretic hormone. Increase dose of diuretic if needed. ■ Concomitant use with **anticholinergic drugs** may increase the risk of urinary retention and/or severe constipation, which may lead to paralytic ileus. ■ **Nucleoside reverse transcriptase inhibitors (NRTIs)** do not appear to induce or inhibit the P450 enzyme pathway, thus no interactions with buprenorphine are expected. ■ **Non-nucleoside reverse transcriptase inhibitors (NNRTIs)** are metabolized principally by CYP3A4. Efavirenz, nevirapine, and etravirine are known CYP3A inducers, whereas delavirdine is a CYP3A inhibitor. Significant pharmacokinetic interactions between NNRTIs (e.g., efavirenz and delavirdine) and buprenorphine have been shown in clinical studies, but these pharmacokinetic interactions did not result in any significant pharmacodynamic effects. Monitor patients and adjust buprenorphine dose if indicated. ■ Some **protease inhibitors** (PIs) with CYP3A4 inhibitory activity (atazanavir and atazanavir/ritonavir) resulted in elevated levels of buprenorphine and norbuprenorphine. Symptoms of opioid excess and sedation have been reported. Monitor patient and reduce dose if indicated.

SIDE EFFECTS

Sedation is the most common side effect. Other commonly reported side effects include constipation, dizziness, headache, hypotension, hypoventilation, miosis, nausea, sweating, vertigo, and vomiting. Serious side effects include acute and chronic hypersensitivity reactions (e.g., anaphylaxis, angioneurotic edema, bronchospasm, hives, pruritus, rash), addiction, adrenal insufficiency, increased intracranial pressure, life-threatening respiratory depression, neonatal opioid withdrawal syndrome, QTc prolongation, seizure, and severe hypotension. Numerous other reactions have been reported in fewer than 1% of patients.

Overdose:

Airway obstruction (partial or complete), atypical snoring, bradycardia, cold and clammy skin, constricted pupils, death, hypotension, pulmonary edema, respiratory depression, skeletal muscle flaccidity, and somnolence progressing to stupor and coma. Marked mydriasis rather than miosis may be seen with hypoxia in overdose situations.

Post-Marketing:

Cases of serotonin syndrome have been reported with concomitant use of opioids and serotonergic drugs.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. An opioid antagonist (e.g., naloxone hydrochloride) will help to reverse respiratory depression but should be reserved for clinically significant respiratory or circulatory depression. Repeat dosing of the antagonist may be needed due to the long-acting depressant effects of buprenorphine (36 to 48 hours). Carefully monitor the patient until spontaneous respiration is reliably re-established. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Treat anaphylaxis and resuscitate as necessary.

BUSULFAN BBW

(byou-**SUL**-fan)
Busulfex
Antineoplastic (alkylating agent)
pH 3.4 to 3.9

USUAL DOSE

Administered in combination with cyclophosphamide as a component of a conditioning regimen before bone marrow transplantation (BMT) or peripheral blood progenitor cell replacement.

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

Premedicate patients with anticonvulsants (e.g., benzodiazepines, phenytoin, valproic acid, or levetiracetam). Administer anticonvulsants 12 hours before the first dose of busulfan and continue to 24 hours after the last dose of busulfan. Administer an antiemetic (e.g., $5HT_3$ antiemetics such as ondansetron). Continue antiemetic administration on a fixed schedule throughout busulfan therapy. See Monitor, Drug/Lab Interactions, and Side Effects.

Patients weighing more than 12 kg:

Busulfan:

0.8 mg/kg of ideal body weight (IBW) or actual body weight, whichever is lower, administered through a central venous catheter as a 2-hour infusion every 6 hours for 4 consecutive days for a total of 16 doses (BMT days −7, −6, −5, and −4 [7, 6, 5, 4 days before BMT, respectively]). Before and after each infusion, flush the catheter line with 5 mL NS or D5W.

Cyclophosphamide:

Six hours after the 16th busulfan dose (BMT day −3 [3 days before BMT]), begin cyclophosphamide at a dose of 60 mg/kg/day as a 1-hour infusion for 2 days (BMT days −3, −2). Before and after each infusion, flush the catheter line with 5 mL NS or D5W. Administer hematopoietic progenitor cells on Day 0.

PEDIATRIC DOSE

See Maternal/Child.
Initial doses are based on a small trial and are unlabeled. Therapeutic drug monitoring and dose adjustment based on AUC determination following the first dose are recommended. See manufacturer's literature for details.

Actual body weight equal to or less than 12 kg:

1.1 mg/kg of busulfan. See all comments and cyclophosphamide dose in Usual Dose.

Actual body weight greater than 12 kg:

See Usual Dose.

DOSE ADJUSTMENTS

In obese or severely obese patients, dose should be based on an adjusted ideal body weight (AIBW). Calculate as follows:

$$\text{AIBW} = \text{IBW} + 0.25 \times (\text{Actual weight [kg]} - \text{IBW})$$

DILUTION

Specific techniques required; see Precautions.

Supplied in vials containing 60 mg/10 mL (6 mg/mL). Must be diluted before infusion with either NS or D5W. The diluent volume should be 10 times the busulfan volume to ensure a final concentration of approximately 0.5 mg/mL. Remove calculated dose of busulfan from vial. Inject the contents of the syringe into an intravenous bag or syringe that contains the calculated amount of diluent. Always add the busulfan to the diluent rather than the diluent to the busulfan. Mix thoroughly by inverting several times. The dose for a 70-kg patient would be prepared using the following steps:

1. 70 kg × 0.8 mg/kg = 56 mg.
2. 56 mg ÷ 6 mg/mL = 9.3 mL busulfan needed.
3. 9.3 × 10 = 93 mL.
4. Add 9.3 mL of busulfan to 93 mL of NS or D5W.

Filters:

Specific information not available.

Storage:

Store unopened vials refrigerated at 2° to 8° C (36° to 46° F). Busulfan diluted with NS or D5W is stable for 8 hours at room temperature, but infusion must be completed within that time. When diluted with NS and refrigerated, it is stable for 12 hours, but infusion must be completed within that time.

COMPATIBILITY

Busulfan is **incompatible** with polycarbonate. Do not use any infusion components (e.g., IV tubing, filter, needles, syringes) containing polycarbonate with busulfan. Manufacturer states, "Do not infuse concomitantly with another intravenous solution of unknown **compatibility.** Flush central venous catheter line before and after administration with at least 5 mL of NS or D5W."

RATE OF ADMINISTRATION

Administer through a central venous catheter. Use an administration set with minimal residual hold-up volume (2 to 5 mL) for product administration. Before and after each infusion, flush the catheter line with 5 mL NS or D5W.

Busulfan:

Infuse over 2 hours using an infusion pump.

Cyclophosphamide:

Infuse over 1 hour.

ACTIONS

A bifunctional alkylating agent. Cell cycle phase–nonspecific. Interferes with DNA replication, leading to cytotoxicity and cell death. Distributes equally into plasma and CSF. Metabolized in the liver. Excreted partially in the urine, primarily as metabolites.

INDICATIONS AND USES

For use in combination with cyclophosphamide as a conditioning regimen prior to allogeneic hematopoietic progenitor cell transplantation for chronic myelogenous leukemia.

Unlabeled uses:

As part of a conditioning regimen in patients 5 months to 16 years of age undergoing allogeneic hematopoietic stem cell transplantation (HSCT).

CONTRAINDICATIONS

Previous hypersensitivity to busulfan or any of its components (polyethylene glycol and dimethylacetamide).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ Administered by or under the direction of a physician who is experienced in allogeneic hematopoietic stem cell transplantation, the use of cancer chemotherapeutic drugs, and the management of patients with severe pancytopenia. ■ Adequate diagnostic and treatment facilities must be readily available to manage therapy and any complications that arise. ■ Severe and prolonged myelosuppression, including granulocytopenia, thrombocytopenia, anemia, or any combination of these will occur. Hematopoietic progenitor cell transplantation is required to prevent potentially fatal complications of the prolonged myelosuppression. ■ Seizures have been reported. Use caution when administering to patients with a history of seizures or head trauma or patients who are receiving other potentially epileptogenic drugs (e.g., imipenem-cilastatin, meperidine). Anticonvulsant prophylactic therapy should be initiated before busulfan treatment; see Premedication. ■ High busulfan AUC values (greater than 1,500 µM • min) may be associated with an increased risk of developing hepatic veno-occlusive disease (HVOD). Patients who have received prior radiation therapy, three or more cycles of chemotherapy, or a prior progenitor cell transplant may be at an increased risk of developing hepatic HVOD with the recommended busulfan dose and regimen. ■ Cardiac tamponade has been reported in pediatric patients with thalassemia who received high doses of oral busulfan and cyclophosphamide as the preparatory regimen for hematopoietic progenitor cell transplantation. ■ Bronchopulmonary dysplasia with pulmonary fibrosis is a rare but serious complication following chronic busulfan therapy. Average onset of symptoms is 4 years after therapy (range: 4 months to 10 years). ■ May cause cellular dysplasia in many organs. Dysplasia may be severe enough to cause difficulty in interpretation of exfoliative cytologic examinations of the lungs, bladder, breast, and the uterine cervix.

Monitor:

Obtain a baseline and a daily CBC, including white blood cell differentials and quantitative platelet count, during treatment and until engraftment is demonstrated. Absolute neutrophil count (ANC) dropped below 0.5×10^9/L at a median of 4 days posttransplant and recovered at a median of 13 days when prophylactic G-CSF was used. Thrombocytopenia (platelets less than 25,000/mm^3 or platelet transfusion required) occurred at a median of 5-6 days. ■ Monitor for signs of local or systemic infection or bleeding. Antibiotic therapy and platelet and RBC support should be used when medically indicated. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Serum transaminases, alkaline phosphatase, and bilirubin should be obtained daily through transplant day 28 to monitor for signs of hepatotoxicity and the onset of hepatic VOD. ■ Monitor for S/S of cardiac tamponade. Abdominal pain and vomiting preceded the tamponade in most patients. ■ Obtain baseline and periodic uric acid concentrations.

Patient Education:

Effective birth control is recommended for females of reproductive potential and males with female partners of reproductive potential during and for 6 months (females) and 3 months (males) after treatment with busulfan. ■ Report a suspected pregnancy immediately. ■ Prolonged low blood cell counts expected. Hematopoietic progenitor cell infusion required. ■ Inform provider of any S/S of infection (e.g., fever). ■ Regular blood monitoring required to detect possible hepatotoxicity and HVOD. ■ May cause temporary or permanent infertility in both males and females and in prepubertal girls and females of childbearing potential treated with high-dose busulfan during the conditioning regimen prior to allogenic hematopoietic cell transplantation. ■ May cause seizures; medication will be provided to prevent them. Report a history of seizure or head trauma. ■ Report symptoms of abdominal pain, cough, SOB, and vomiting. Symptoms of bronchopulmonary dysplasia (cough and SOB) can occur several months or years after therapy. ■ See Appendix D.

Maternal/Child:

Avoid pregnancy. Can cause fetal harm. Effective contraception required. ■ Discontinue breast-feeding. ■ Safety and efficacy for use in pediatric patients not established. Clearance has been shown to be higher in pediatric patients than in adults, necessitating the development of alternative dosing regimens for oral busulfan in pediatric patients. A recent small pharmacokinetic study suggests an unlabeled dosing regimen; see Pediatric Dose and manufacturer’s literature.

Elderly:

Clinical studies did not include sufficient numbers of subjects 65 years of age and over to determine whether they respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

Itraconazole (Sporanox) and **metronidazole** (Flagyl) decrease busulfan clearance. Metronidazole decreases busulfan clearance more than itraconazole and has been associated with increased busulfan toxicity. Fluconazole (200 mg) has been used with busulfan. ■ Busulfan clearance decreased with concomitant use with **deferasirox**. To avoid increased exposure to busulfan, discontinue iron chelating agents well in advance of busulfan administration. ■ **Phenytoin** increases the clearance of busulfan. Because the pharmacokinetics of busulfan were studied in patients treated with phenytoin, the clearance of busulfan at the recommended dose may be lower and the AUC higher in patients not treated with phenytoin. ■ **Acetaminophen** may decrease clearance of busulfan. Avoid administration of acetaminophen 72 hours prior to or with busulfan therapy. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs.

SIDE EFFECTS

Profound myelosuppression, including granulocytopenia, thrombocytopenia, anemia, or a combination of these, will occur in 100% of patients. ■ The most common adverse reactions were abdominal pain, anorexia, anxiety, diarrhea, fever, headache, hyperglycemia, hypokalemia, hypomagnesemia, insomnia, myelosuppression, nausea, stomatitis, vomiting. Other nonhematologic adverse events occurring in more than 20% of patients include abdominal enlargement, ALT elevation, asthenia, back pain, chest pain, chills, constipation, cough, creatinine elevation, depression, dizziness, dry mouth, dyspepsia, dyspnea, edema, epistaxis, hyperbilirubinemia, hypersensitivity reactions, hypertension, hypocalcemia, hypokalemia, hypomagnesemia, infection, inflammation or pain at injection site, lung disorders, pain, pruritus, rash, rectal disorder, rhinitis, tachycardia, thrombosis, vasodilation (flushing or hot flashes). ■ Bronchopulmonary dysplasia, cardiac tamponade, cellular dysplasia, graft-versus-host disease, hepatic veno-occlusive disease, infection, seizures, and death have also been reported. ■ Dimethylacetamide (DMA), the solvent used in busulfan formulation, has been associated with adverse reactions such as confusion, hallucinations, hepatotoxicity, lethargy, and somnolence. The relative contribution of DMA to neurologic and hepatic toxicities observed with busulfan is difficult to determine. ■ Numerous other side effects have occurred.

Post-Marketing:

Febrile neutropenia, thrombotic microangiopathy, tooth hypoplasia, tumor lysis syndrome, and severe bacterial, viral (e.g., CMV viremia), and fungal infections and sepsis.

ANTIDOTE

Keep physician informed of all side effects. Treat minor side effects symptomatically.

There is no known antidote to busulfan other than hematopoietic progenitor cell transplantation. In the absence of hematopoietic progenitor cell transplantation, the recommended dosage of busulfan injection constitutes an overdose. Monitor hematologic status closely, and institute supportive measures as indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Dialysis may be considered in an overdose. Treat hypersensitivity reactions as appropriate (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids).

BUTORPHANOL TARTRATE BBW

(byou-**TOR**-fah-nohl **TAHR**-trayt)
Butorphanol Tartrate PF, Stadol, Stadol PF
Narcotic analgesic (agonist-antagonist)
Anesthesia adjunct
pH 3 to 5.5

USUAL DOSE

Pain control:

1 mg. Repeat every 3 to 4 hours as necessary. Range is 0.5 to 2 mg.

Preoperative or preanesthetic:

2 mg 60 to 90 minutes before surgery. Individualize dose. Usually given IM.

Labor:

1 to 2 mg at full term in early labor; may be repeated after 4 hours. Use alternate analgesia if delivery is expected to occur within 4 hours.

Adjunct to balanced anesthesia:

2 mg just before induction or 0.5 to 1 mg in increments during anesthesia. Increments may be up to 0.06 mg/kg and should be based on previous sedative, analgesic, and hypnotic drugs. Patients seldom require less than 4 mg or more than 12.5 mg. Administered only under the direction of the anesthesiologist.

DOSE ADJUSTMENTS

Reduce dose to one-half of the recommended dose and increase the interval between doses to at least 6 hours for impaired liver or renal function and in the elderly; adjust as indicated by patient response. ■ Another source suggests that patients with a glomerular filtration rate (GFR) of 10 to 50 mL/min receive 75% of the usual dose given at the normal dosage interval and that patients with a GFR less than 10 mL/min receive 50% of the usual dose given at the normal dosage interval. No dose adjustment is necessary for patients with a GFR greater than 50 mL/min. ■ Reduce dose when other CNS depressants have been given and in the immediate postoperative period. Use the smallest effective dose and extend intervals between doses. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted. Avoid aerosol spray while preparing a syringe for use. Rinse with cool water following skin contact. Available preservative free.

Storage:

Store at CRT. Protect from light and freezing.

COMPATIBILITY

Compatibility information not available from manufacturer.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each 2 mg or fraction thereof over 3 to 5 minutes. Frequently titrated according to symptom relief and respiratory rate.

ACTIONS

A potent narcotic analgesic with some narcotic agonist-antagonist effects. Exact mechanism of action is unknown. Analgesia similar to morphine is produced. Does produce respiratory depression, but this does not increase markedly with larger doses. Pain relief is effected almost immediately, peaks at 30 minutes, and lasts about 2 to 4 hours. Causes some hemodynamic changes that increase the workload of the heart. Metabolized in the liver. Excreted in urine and feces. Crosses the blood-brain barrier and placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of moderate to severe pain. ■ Preoperative or preanesthetic medication, as a supplement to anesthesia. ■ Relief of pain during early labor.

CONTRAINDICATIONS

Hypersensitivity to butorphanol or its components (some products contain benzethonium chloride).

PRECAUTIONS

Butorphanol exposes patients and other users to the risks of opioid addiction, abuse, and misuse, which can lead to overdose and death. Assess each patient’s risk before prescribing butorphanol, and monitor all patients regularly for the development of these behaviors and conditions. Strategies to reduce the risk of diversion or misuse should be used by health care facilities that use this and other controlled substances. ■ See prescribing information for further discussion regarding abuse, addiction, physical dependence, and tolerance. ■ Not used for narcotic-dependent patients because of antagonist activity. ■ May increase cardiac workload; use in myocardial infarction, ventricular dysfunction, and coronary insufficiency only if benefits outweigh risks. ■ Use caution in respiratory depression or difficulty from any source, obstructive respiratory conditions, head injury, and impaired liver or kidney function. ■ May elevate cerebrospinal pressure. ■ In overdose situations, always consider the possibility of multiple drug ingestion. ■ Cases of serotonin syndrome have been reported during concomitant use of butorphanol with serotonergic drugs.

Monitor:

Naloxone, oxygen, and controlled respiratory equipment must be available. Duration of action of butorphanol usually exceeds that of naloxone; repeated dosing may be necessary. ■ Observe patient frequently and monitor vital signs. ■ Monitor for respiratory depression, especially during initiation of therapy (within the first 24 to 72 hours) or after a dose increase. ■ Keep patient supine to minimize side effects; orthostatic hypotension and fainting may occur. Observe closely during ambulation. ■ Monitor for S/S of serotonin syndrome (e.g., mental status changes [e.g., agitation, coma, hallucinations], autonomic instability [e.g., hyperthermia, labile blood pressure, tachycardia], neuromuscular aberrations [e.g., hyperreflexia, incoordination, rigidity], and/or GI symptoms [e.g., diarrhea, nausea, vomiting]). Onset of symptoms may occur within hours to days of concomitant use of opioids with serotonergic drugs. ■ Pain control usually more effective with routinely administered doses. Determine appropriate interval through clinical assessment.

Patient Education:

Avoid use of alcohol or other CNS depressants (e.g., antihistamines, diazepam). ■ Promptly report S/S of serotonin syndrome. ■ Use caution performing any task requiring alertness; may cause dizziness, euphoria, and sedation. ■ Request assistance for ambulation. ■ May be habit forming.

Maternal/Child:

Category C: safety for use in pregnant women before 37 weeks' gestation not established; use only if benefit justifies potential risk to fetus. ■ Prolonged use of butorphanol during pregnancy can result in neonatal opioid withdrawal syndrome, which may be life threatening if not recognized and treated. Infants born to mothers receiving butorphanol during pregnancy should be monitored closely and treated for neonatal opioid withdrawal syndrome, if indicated. See literature for treatment protocols. ■ Has been associated with transient (10 to 90 minutes) sinusoidal fetal heart rate patterns. Use caution if abnormal fetal heart rate is present. Alternative analgesia suggested if delivery is expected to occur within 4 hours. ■ Use caution in breast-feeding; an estimated 4 mcg/L has been found in breast milk; monitor for excess sedation and/or respiratory depression. ■ Safety and effectiveness for use in pediatric patients under 18 years of age not established.

Elderly:

Mean half-life may be extended by 25%, may be more sensitive to effects (e.g., respiratory depression, constipation, dizziness, urinary retention). ■ Analgesia should be effective with lower doses; see Dose Adjustments. ■ Consider decreased organ function, concomitant disease, or other drug therapy.

DRUG/LAB INTERACTIONS

Concomitant use of butorphanol with **benzodiazepines** and other CNS depressants (e.g., sedative/hypnotics, anxiolytics, tranquilizers, muscle relaxants, general anesthetics, antipsychotics, other opioids, alcohol) may result in profound sedation, respiratory depression, coma, and death. Hypotension can also occur. Reserve concomitant use for patients for whom alternative treatment options are inadequate. Limit dose and duration of treatment to the minimum required and monitor patients carefully for S/S of respiratory depression and sedation. ■ Serotonin syndrome has been reported with the concomitant use of opioids, including butorphanol, and other **drugs that affect the serotonergic neurotransmitter system** (e.g., selective serotonin reuptake inhibitors [SSRIs], serotonin and norepinephrine reuptake inhibitors [SNRIs], tricyclic antidepressants [TCAs], triptans, 5-HT3 receptor antagonists, mirtazapine, trazodone, tramadol, MAO inhibitors, linezolid, and intravenous methylene blue). Careful observation, particularly during treatment initiation and dose adjustment, is required with concomitant use. ■ **Medications that affect hepatic metabolism of drugs** (e.g., aminophylline, cimetidine, erythromycin) may interfere with the metabolism of butorphanol. Reduced doses of butorphanol and/or longer intervals between doses may be indicated. ■ May decrease analgesic effects of **other narcotics;** avoid concurrent use. ■ May cause an increase in conjunctival changes with **pancuronium.**

SIDE EFFECTS

Dizziness, nausea and/or vomiting, and somnolence occur most frequently. Abdominal pain, anorexia, anxiety, asthenia, bronchitis, clammy skin, confusion, constipation, cough, diplopia, dizziness, drug dependence, dry mouth, dyspnea, euphoria, floating feeling, flushing, hallucinations, headache, hypersensitivity reactions (e.g., pruritus), hypotension, insomnia, lethargy, nervousness, palpitations, paresthesia, respiratory depression, sweating, tremor, unusual dreams, vasodilation, vertigo, warmth. May cause increased pulmonary artery pressure, pulmonary wedge pressure, left ventricular end-diastolic pressure, systemic arterial pressure, pulmonary vascular resistance, and cardiac workload.

Overdose:

Cardiovascular insufficiency, hypoventilation, coma, and death. May be associated with ingestion of multiple drugs.

ANTIDOTE

With increasing severity of any side effect or onset of symptoms of overdose, discontinue the drug and notify the physician. Most side effects will be treated symptomatically. Treat hypertension with antihypertensives (e.g., nitroglycerin, nitroprusside sodium). Naloxone hydrochloride will reverse respiratory depression. Duration of action of butorphanol usually exceeds that of naloxone; repeated dosing may be necessary. A patent airway, adequate ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Vasodilation may cause hypotension.

C

C1 ESTERASE INHIBITOR (HUMAN OR RECOMBINANT)

(C 1 **ES**-ter-ase in-**HIB**-it-or)
Berinert, Cinryze, Ruconest
Protein C1 Inhibitors

Available C1 esterase inhibitor products include:

Berinert:
Plasma-derived C1 esterase inhibitor (human) pH 4.5 to 8.5

Cinryze:
Plasma-derived C1 esterase inhibitor (human) pH 6.6 to 7.4

Ruconest:
(Recombinant) C1 esterase inhibitor pH 6.8

USUAL DOSE (International units [IU])

Berinert

Treatment of an acute attack:
20 international units/kg (IU/kg) as an IV injection. Doses lower than 20 international units/kg (IU/kg) should not be administered.

Cinryze

Routine prophylaxis dosing:
1,000 units as an IV injection over 10 minutes (1 mL/min). May be repeated every 3 or 4 days as necessary for routine prophylaxis against angioedema attacks in patients with hereditary angioedema (HAE).

Ruconest

Treatment of an acute attack:
50 international units/kg (IU/kg) with a maximum of 4,200 international units (IU) administered as a slow IV injection over approximately 5 minutes. If symptoms persist,

a second dose may be administered. Do not exceed 4,200 international units/dose (IU/dose).

DILUTION (International units [IU])

Berinert

Available in a kit containing one 500–international unit (IU) vial of Berinert, one 10-mL vial of SWFI, one Mix2Vial filtered transfer set, and one alcohol swab. Bring components to room temperature. Berinert is a lyophilized concentrate and requires reconstitution. The Mix2Vial transfer set provided requires a specific technique to accomplish reconstitution; see manufacturer's literature for instructions. Alternately, for each vial of Berinert and provided diluent, place all components on a flat surface, remove the flip caps from the drug and diluent vials, swab the vials with alcohol, and allow them to dry. Insert one end of a double-ended transfer needle into the diluent. Invert the diluent bottle and insert the other end of the transfer needle into the drug vial. Diluent will be drawn into the drug vial by a vacuum. Remove the transfer device and diluent vial. Gently swirl the drug vial to fully dissolve. Solution should be colorless, clear, and free from visible particles. Do not use if solution is cloudy, discolored, or contains particulates. Concentration equals 50 units/mL. Calculate volume required to supply the calculated dose. Attach a vented filter spike to a 10-mL (or larger) syringe and withdraw the contents. Contents of multiple vials may be pooled in a single administration device (e.g., syringe). Use a new double-ended transfer needle and a new vented filter spike or a new unused Mix2Vial for each vial requiring reconstitution.

Cinryze

If refrigerated, bring components to RT (two 500-unit vials of Cinryze and two 5-mL vials of SWFI [not supplied by manufacturer]). Use of a silicone-free syringe is recommended for reconstitution and administration. Access the diluent vial before the Cinryze vial to prevent loss of vacuum. For each 500-unit vial, insert one end of a double-ended transfer needle into the SWFI diluent. Invert the bottle of diluent and rapidly insert the other end of the transfer needle into the slightly angled Cinryze vial. Diluent will be drawn into the Cinryze vial by a vacuum. Do not use if there is no vacuum. Remove the transfer device and diluent vial. Gently swirl the Cinryze vial until the powder is completely dissolved. Do not use if solution is turbid or discolored (should be colorless to slightly blue and clear). Attach a filter needle to a 10-mL syringe and withdraw 500 units (5 mL) from each vial (total dose 1,000 units in 10 mL [100 units/mL]).

Ruconest

Bring components to room temperature (vials of Ruconest and SWFI as diluent [not supplied by manufacturer]). Remove the flip caps from the drug and diluent vials, swab the vials with alcohol, and allow them to dry. Using the syringe/needle or syringe/vial adapter, withdraw 14 mL of SWFI from the diluent vial. Remove the syringe and transfer the diluent to the Ruconest vial. Add the diluent slowly to avoid forceful impact on the powder. Swirl the vial slowly to mix and avoid foaming. If indicated, repeat this procedure using another 14 mL of diluent using a new vial adapter and a second vial of

Ruconest. Concentration equals 150 international units/mL (IU/mL). Calculate volume required to supply the calculated dose and draw up into a syringe. Contents of both vials may be pooled into a single administration syringe. Do not use if solution is cloudy, discolored, or contains particulates.

Filters:

Berinert:

A Mix2Vial filtered transfer set is provided for each single-use dose or, alternately, a double-ended needle and a vented filter spike are required.

Cinryze and Ruconest:

Specific information not available.

Storage:

All Formulations: Store in carton at 2° to 25° C (36° to 77° F) until ready for use. Do not freeze. Protect from light. Do not use beyond expiration date. For single use only. Discard unused drug.

Berinert:

Reconstituted solution must be used within 8 hours; do not refrigerate or freeze.

Cinryze:

Reconstituted solution must be administered at RT within 3 hours of preparation.

Ruconest:

Use reconstituted solution immediately, or refrigerate and use within 8 hours. Do not freeze.

COMPATIBILITY

Berinert:

Manufacturer states, “Do not mix Berinert with other medicinal products, and administer by a separate infusion line.”

Cinryze:

Manufacturer states, “Do not mix with other materials.”

Ruconest:

Manufacturer states, “Do not mix with other medicinal products or solutions. Administer by a separate infusion line.”

RATE OF ADMINISTRATION

Berinert:

A single dose at a rate of approximately 4 mL/min.

Cinryze:
A single dose equally distributed over 10 minutes (1 mL/min).

Ruconest:
A single dose equally distributed over approximately 5 minutes.

ACTIONS

C1 esterase inhibitor is a normal constituent of human blood and is a serine proteinase inhibitor. It has an important inhibiting potential on several of the major cascade systems, including the complement system, the intrinsic coagulation (contact) system, the fibrinolytic system, and the coagulation cascade. Hereditary angioedema (HAE) patients have low levels of endogenous or functional C1 esterase inhibitor. Although the events that induce attacks of angioedema in HAE patients are not well defined, it is thought that increased vascular permeability and the clinical manifestation of HAE attacks (e.g., local tissue swelling of hands, feet, limbs, face, intestinal tract, and airway [larynx or trachea]) are primarily mediated through contact system activation. Suppression of contact system activation by C1 esterase inhibitor through the inactivation of plasma kallikrein and factor XIIa is thought to modulate vascular permeability by preventing the generation of bradykinin. Supplying additional C1 esterase inhibitor activity by IV injection facilitates the normal process. Plasma levels of C1 inhibitor increase within 1 hour or less of IV administration of Cinryze. The mean half-life is 22 hours for **Berinert,** 56 hours for **Cinryze,** and 2.5 hours for **Ruconest.**

INDICATIONS AND USES

Berinert:

Treatment of acute abdominal, facial, or laryngeal attacks of hereditary angioedema (HAE) in adult and adolescent patients. ■ Safety and effectiveness for use as prophylactic therapy not established.

Cinryze:

Routine prophylaxis against angioedema attacks in adolescent and adult patients with HAE.

Ruconest:

Treatment of acute attacks in adult and adolescent patients with HAE.

Limitation of use:

Ruconest: Effectiveness not established in HAE patients with laryngeal attacks.

CONTRAINDICATIONS

All Formulations:

Known life-threatening hypersensitivity reactions, including anaphylaxis to C1 esterase inhibitor preparations.

Ruconest:

Is contraindicated in patients with a history of allergy to rabbits or rabbit-derived products.

PRECAUTIONS

All Formulations:

For intravenous use only. ■ Initiate treatment under the supervision of a qualified health care professional experienced in the treatment of HAE. ■ Severe hypersensitivity reactions, including anaphylaxis, may occur. Epinephrine should be immediately available. See Antidote. ■ Serious arterial and venous thromboembolic (TE) events (e.g., basilar artery thrombosis, multiple pulmonary microemboli, and thrombosis) have been reported at recommended doses of C1 esterase inhibitor products, and other TE events (e.g., myocardial infarction, pulmonary embolism, arterial thrombosis, deep vein thrombosis) have been reported in patients receiving off-label high-dose C1 esterase inhibitor therapy. Risk factors may include the presence of an indwelling venous catheter/access device, prior history of thrombosis, underlying atherosclerosis, use of oral contraceptives or certain androgens, morbid obesity, and immobility. Weigh benefits of treatment versus risk.

Berinert and Cinryze:

Made from human plasma and may contain infectious agents (e.g., HIV, Creutzfeldt-Jakob disease, hepatitis B, or hepatitis C). Numerous steps in the manufacturing process are used to reduce the potential for infection.

Monitor:

All Formulations: Observe for symptoms of a hypersensitivity reaction (e.g., anaphylaxis, generalized urticaria, hives, hypotension, tightness in the chest, wheezing). Reaction may occur during injection or after injection is complete. ■ Symptoms of an HAE attack may be similar to S/S of hypersensitivity reactions. Evaluate carefully to initiate the correct treatment. There is usually no itching or hives with an HAE attack. ■ Monitor patients with known risk factors for thrombotic events during and after administration; see Precautions.

Patient Education:

All Formulations:

Inform patients of the risks for infectious agent transmission and of safety precautions taken during the manufacturing process. ■ Promptly report symptoms of a hypersensitivity reaction (e.g., difficulty breathing, feeling faint, hives, itching, tightness in the chest, wheezing). ■ Promptly report symptoms of a possible thrombosis (e.g., altered consciousness or speech; loss of sensation or motor power; new-onset swelling and pain in the abdomen, chest, or limbs; shortness of breath). ■ Appropriately trained patients may self-administer upon recognition of an HAE attack. However, given the potential for airway obstruction during an acute laryngeal HAE attack, patients experiencing such an attack should be advised to seek immediate medical attention after self-administration of **Berinert**. ■ Discuss all medications used (e.g., prescription, nonprescription, over-the-counter, herbal, supplements) with the physician. ■ Consult a health care professional before travel.

Maternal/Child:

Berinert and Cinryze:

Category C: safety and effectiveness for use during pregnancy, labor, and delivery have not been established; use only if clearly needed.

Ruconest:

Category B: safety and effectiveness during pregnancy, labor, and delivery have not been established; use only if clearly needed.

All Formulations:

Not known if C1 esterase inhibitor is secreted in human milk; use only if clearly needed during breast-feeding. ■ ***Berinert:*** Safety and effectiveness for use in pediatric patients under 12 years of age not established. ■ ***Cinryze:*** Safety and effectiveness for use in neonates, infants, or other pediatric patients not established. Clinical studies included patients 9, 14, and 16 years of age. ■ ***Ruconest:*** Safety and effectiveness were evaluated in 17 adolescent patients (13 to 17 years of age) treated for 52 HAE attacks with no serious adverse reactions. Abdominal pain, headache, and oropharyngeal pain did occur.

Elderly:

All Formulations:

Numbers in clinical studies insufficient to determine if the elderly respond differently than do younger subjects.

DRUG/LAB INTERACTIONS

All Formulations:

No drug interaction studies have been conducted.

SIDE EFFECTS

Berinert:

The most common side effect observed was dysgeusia (an altered sense of taste). An increase in the severity of pain associated with HAE was the most serious side effect during clinical trials. Other reported side effects include abdominal pain, back pain, diarrhea, facial pain, headache, muscle spasm, nausea, and vomiting.

Cinryze:

The most common side effects reported include headache, nausea, rash, and vomiting. The most serious reaction observed in clinical studies was a cerebrovascular accident. Hypersensitivity reactions, including anaphylaxis, hives, hypotension, tightness of the chest, urticaria, and wheezing, have occurred.

Ruconest:

The most common side effects reported include diarrhea, headache, and nausea. Hypersensitivity with anaphylaxis was the most serious reaction reported.

Post-Marketing: Berinert:

Reported side effects from use outside the United States include hypersensitivity/anaphylactic reactions, viral transmission (e.g., acute hepatitis C), chills, fever, and injection site pain or redness.

Cinryze:

Local infusion site reactions (including inflammation or hematoma) and thromboembolic events (including catheter-related and deep venous thrombosis, transient ischemic attack, and stroke).

Ruconest:

Abdominal pain and rash.

ANTIDOTE

All Formulations:

Keep the physician informed of side effects. Interrupt or discontinue injection if indicated (e.g., hypersensitivity reaction, thrombotic event). If appropriate and if symptoms subside, infusion may be resumed at a tolerated rate. ■ Discontinue C1 esterase inhibitor and treat anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

CABAZITAXEL BBW

(ka-**BAZ**-i-**TAX**-el)
Jevtana
Antineoplastic agent (taxane)

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Premedication:

Must be premedicated at least 30 minutes before each dose to reduce the risk and/or severity of hypersensitivity reactions. Usual regimen includes IV administration of an antihistamine (diphenhydramine 25 mg or equivalent), a corticosteroid (dexamethasone 8 mg or equivalent steroid), and an H_2 antagonist (famotidine 20 mg).

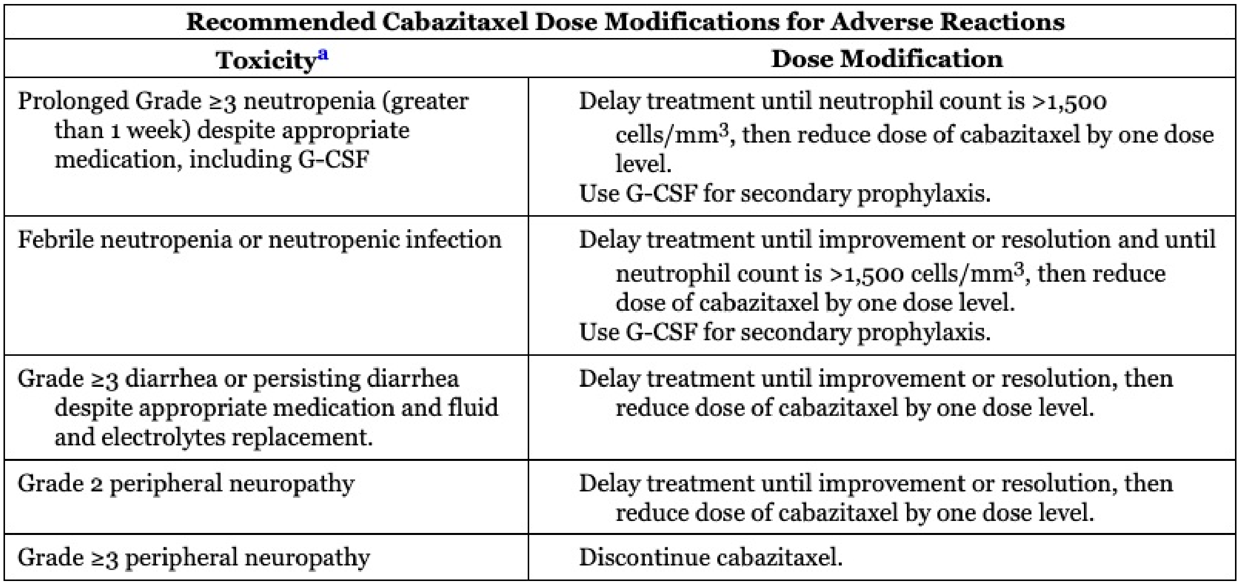
Antiemetic prophylaxis is recommended and may be given orally or IV as needed.

Cabazitaxel:

20 mg/M^2 as a 1-hour infusion every 3 weeks. Given in combination with oral prednisone 10 mg administered daily throughout cabazitaxel treatment. A dose of 25 mg/M^2 can be used in select patients at the discretion of the treating health care provider.

DOSE ADJUSTMENTS

Dose adjustment recommendations for adverse reactions are listed in the following chart.



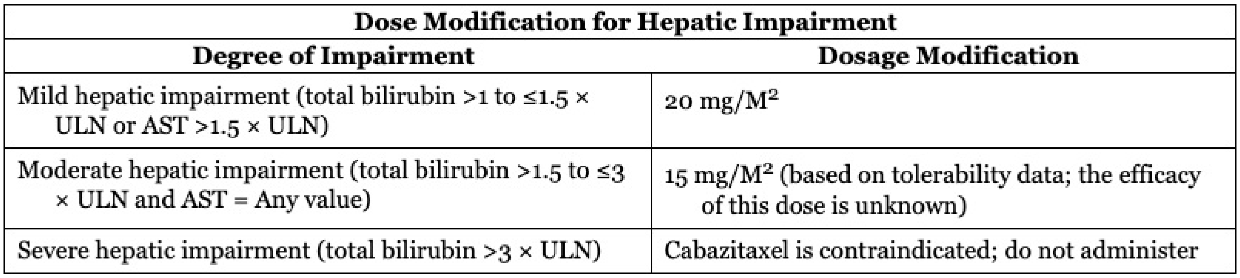
Recommended Cabazitaxel Dose Modifications for Adverse Reactions

Toxicity[a]	Dose Modification
Prolonged Grade ≥3 neutropenia (greater than 1 week) despite appropriate medication, including G-CSF	Delay treatment until neutrophil count is >1,500 cells/mm^3, then reduce dose of cabazitaxel by one dose level. Use G-CSF for secondary prophylaxis.
Febrile neutropenia or neutropenic infection	Delay treatment until improvement or resolution and until neutrophil count is >1,500 cells/mm^3, then reduce dose of cabazitaxel by one dose level. Use G-CSF for secondary prophylaxis.
Grade ≥3 diarrhea or persisting diarrhea despite appropriate medication and fluid and electrolytes replacement.	Delay treatment until improvement or resolution, then reduce dose of cabazitaxel by one dose level.
Grade 2 peripheral neuropathy	Delay treatment until improvement or resolution, then reduce dose of cabazitaxel by one dose level.
Grade ≥3 peripheral neuropathy	Discontinue cabazitaxel.

[a] Toxicities graded in accordance with National Cancer Institute (NCI) Common Terminology Criteria for Adverse Events (CTCAE), version 4.0.

Dose reduction:

Patients at a 20 mg/M^2 dose who require dose reduction should decrease dose of cabazitaxel to 15 mg/M^2. Patients at a 25 mg/M^2 dose who require dose reduction should decrease dose of cabazitaxel to 20 mg/M^2. One additional dose reduction to 15 mg/M^2 may be considered. ■ Dosage modifications based on the degree of hepatic impairment are outlined in the following chart.



Dose Modification for Hepatic Impairment	
Degree of Impairment	**Dosage Modification**
Mild hepatic impairment (total bilirubin >1 to ≤1.5 × ULN or AST >1.5 × ULN)	20 mg/M^2
Moderate hepatic impairment (total bilirubin >1.5 to ≤3 × ULN and AST = Any value)	15 mg/M^2 (based on tolerability data; the efficacy of this dose is unknown)
Severe hepatic impairment (total bilirubin >3 × ULN)	Cabazitaxel is contraindicated; do not administer

■ Avoid coadministration with strong CYP3A inhibitors. If coadministration is required, consider a 25% cabazitaxel dose reduction; see Drug/Lab Interactions.

DILUTION

Specific techniques required; see **Precautions**.

Improper preparation has resulted in overdose. Must be diluted by a specific 2-step process and given as an infusion. Do not use PVC infusion containers and polyurethane infusion sets for preparation or administration. A clear yellow to brownish-yellow viscous solution.

Step 1:

Initially withdraw the **entire contents** of the provided diluent and inject into the vial of cabazitaxel (60 mg/1.5 mL). When transferring the diluent, direct the needle onto the inside wall of the cabazitaxel vial to limit foaming. Gently mix by repeated inversions for at least 45 seconds to ensure full mixing of drug and diluent. Do not shake. Allow to stand for a few minutes to allow most of the foam to dissipate. Should not contain visible particulate matter. Concentration of the resultant dilution is 10 mg/mL. This initially diluted solution should be further diluted immediately (within 30 minutes of entry into the vial) to obtain the final infusion (Step 2).

Step 2:

Withdraw the recommended dose from the 10-mg/mL vial of cabazitaxel. Further dilute into a sterile 250-mL PVC-free container of either NS or D5W for infusion. If a dose greater than 65 mg is required, use a larger volume of NS or D5W infusion so a concentration of 0.26 mg/mL is not exceeded. Concentration of the final solution should be between 0.10 and 0.26 mg/mL. Thoroughly mix by gently inverting the bag or bottle.

Filters:

Use of a 0.22-micron in-line filter is required for administration (not supplied).

Storage:

Before use, store at 25° C (77° F), with excursions permitted between 15° to 30° C (59° to 86° F). Do not refrigerate. Initial diluted solution should be used immediately but must be used within 30 minutes; discard any unused portion. Final infusion solution should be used within 8 hours (including infusion time) at RT or within 24 hours (including infusion time) if refrigerated. Both solutions are supersaturated and may crystallize over time. Discard if crystallization occurs. Discard if either the initial diluted solution or final solution is not clear or appears to have precipitation.

COMPATIBILITY

Manufacturer states, “Do not use PVC infusion containers and polyurethane infusion sets for preparation or administration. Should not be mixed with any other drugs.”

RATE OF ADMINISTRATION

A single dose properly diluted as an infusion over 1 hour. Use of a 0.22-micron in-line filter required for administration. See Dilution and Compatibility.

ACTIONS

An antineoplastic belonging to the taxane class. Prepared by semi-synthesis with a precursor extracted from yew needles. A microtubule inhibitor, it binds to tubulin and promotes its assembly into microtubules while simultaneously inhibiting disassembly. This leads to the stabilization of microtubules, which results in the inhibition of mitotic and interphase cellular functions. Highly protein bound (89% to 92%). Equally distributed between blood and plasma. Extensively metabolized in the liver, mainly by the CYP3A4/5 isoenzyme and to a lesser extent by CYP2C8. Terminal half-life is approximately 95 hours. Mainly excreted in feces as numerous metabolites with minimal excretion of unchanged drug in urine.

INDICATIONS AND USES

Treatment of patients with metastatic castration-resistant prostate cancer previously treated with a docetaxel-containing treatment regimen. Used in combination with oral prednisone.

CONTRAINDICATIONS

Patients with neutrophil counts of equal to or less than 1,500/mm^3. ■ Patients with a history of severe hypersensitivity reactions to cabazitaxel or other drugs formulated with polysorbate 80. ■ Patients with severe hepatic impairment (total bilirubin greater than 3 times the ULN); see Dose Adjustments and Precautions. ■ Pregnancy.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ If initial or fully diluted solution should come into contact with the skin or mucus, immediately and thoroughly wash with soap and water. ■ Bone marrow suppression manifested as neutropenia, anemia, thrombocytopenia, and/or pancytopenia may occur. Neutropenic deaths have been reported. Primary prophylaxis with G-CSF should be considered in high-risk patients (e.g., extensive prior radiation ports, over 65 years of age, poor nutritional status, poor performance status, previous episodes of febrile neutropenia, or other serious comorbidities that may result in increased complications from prolonged neutropenia). Therapeutic use of G-CSF and secondary prophylaxis should be considered in all patients considered to be at increased risk for neutropenia complications. ■ In a randomized trial comparing the 2 doses of cabazitaxel, fewer infectious adverse reactions and deaths related to infections were reported with the 20 mg/M² dose compared with the 25 mg/M² dose. ■ Use caution in patients with a hemoglobin less than 10 Gm/dL. ■ Severe hypersensitivity reactions have occurred; all patients are premedicated to reduce the risk and/or severity of a hypersensitivity reaction. Patients with a history of severe hypersensitivity reactions should not be rechallenged with cabazitaxel. ■ Nausea, vomiting, and severe diarrhea may occur. Deaths related to diarrhea and electrolyte imbalance have occurred. GI hemorrhage and perforation, ileus, enterocolitis, and neutropenic enterocolitis, including fatal outcome, have also been reported. Risk may be increased with neutropenia; age; steroid use; concomitant use of NSAIDs, antiplatelet therapy, or anticoagulants; and patients with a prior history of pelvic radiotherapy, adhesions, ulceration, and GI bleeding; see Drug/Lab Interactions. ■ Renal failure has been reported, including cases with fatal outcome. Most occurred in association with sepsis, dehydration, or obstructive uropathy. ■ Cystitis, radiation cystitis, and hematuria, including that requiring hospitalization, have been reported in patients who previously received pelvic irradiation. Cystitis from radiation recall may occur late in treatment. ■ Interstitial pneumonia/pneumonitis, interstitial lung disease, and acute respiratory distress syndrome have been reported, some with fatal outcome. Patients with underlying lung disease may be at higher risk. Acute respiratory distress syndrome may occur when infection is present. ■ Use with caution in patients with ESRD. ■ Use with caution in patients with mild to moderate hepatic impairment; see Dose Adjustments and Contraindications.

Monitor:

Obtain baseline CBC with differential and platelets. Monitor weekly during Cycle 1 and before each treatment cycle thereafter. Monitor patients with hemoglobin <10 g/dL closely. ■ G-CSF may be administered to reduce the risks of neutropenia complications; see Precautions. ■ Monitor closely for hypersensitivity reactions, especially during the first and second infusions. May occur within the first few minutes, and symptoms may include bronchospasm, generalized rash/erythema, and hypotension. ■ Obtain baseline and periodic bilirubin and liver function tests. Patients with mild to moderate hepatic impairment should be monitored closely. ■ Monitor for nausea, vomiting, and diarrhea. Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. Rehydrate and use antidiarrheal medications as indicated. ■ Monitor for S/S that may indicate serious GI toxicity (e.g., abdominal pain and tenderness, fever, persistent constipation, diarrhea, with or without neutropenia). Evaluate and treat promptly; see Antidote. ■ Monitor for S/S of impending renal failure (dehydration, reduced urine output, increasing SCr or CrCl). Identify causes of renal failure and treat aggressively. ■ Monitor patients who have received prior pelvic irradiation for S/S of cystitis. Medical and/or surgical supportive treatment may be required to treat severe hemorrhagic cystitis. ■ Monitor for new or worsening pulmonary symptoms. Delay or discontinuation of therapy may be indicated. Consider risk versus benefit of continuing therapy if pulmonary symptoms develop. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Avoid pregnancy. Male patients with female partners of reproductive potential should use effective contraception during treatment and for 3 months after the final dose of cabazitaxel. ■ May impair fertility in males of reproductive potential. ■ Routine monitoring of blood counts imperative. ■ Oral prednisone must be taken as prescribed. ■ Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face). ■ May cause severe and/or fatal infections, dehydration, and renal failure. Take your temperature often and promptly report a fever. ■ Promptly report burning on urination, cough, decreased urine output, hematuria, new or worsening pulmonary symptoms, muscle aches, and/or significant diarrhea or vomiting. ■ Drug interactions may occur; review prescription and nonprescription drugs with your physician. ■ Certain side effects may be more frequent or severe in the elderly. ■ See Appendix D, p. 1311.

Maternal/Child *(cabazitaxel is not indicated for female patients):*

Contraindicated in pregnancy. Can cause fetal harm. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in efficacy were observed. Patients over 65 years of age are more likely to experience fatal outcomes not related to disease progression and certain serious adverse reactions, including neutropenia and febrile neutropenia. The incidence of asthenia, constipation, dehydration, diarrhea, dizziness, dyspnea, fatigue, fever, and urinary tract infections was also increased in the elderly. Monitor the elderly closely for S/S of adverse reactions.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ Prednisone administered at 10 mg daily did not affect the pharmacokinetics of cabazitaxel. ■ Primarily metabolized through CYP3A. Concomitant administration with **strong CYP3A4 inhibitors** (e.g., atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, and voriconazole) should be avoided if possible. Plasma concentration of cabazitaxel is expected to increase. If concomitant administration is required, consider cabazitaxel dose reduction; see Dose Adjustments. ■ Concomitant administration with **rifampin**, a strong CYP3A4 inducer, decreased the plasma concentration of cabazitaxel. Although no formal drug interactions have been conducted, it has been recommended that coadministration with **strong CYP3A4 inducers** (e.g., carbamazepine, phenytoin, phenobarbital, rifabutin, rifampin, and rifapentine) be avoided. ■ Avoid use of **St. John's wort;** may also decrease concentration of cabazitaxel. ■ Cabazitaxel is not an inhibitor or inducer of CYP3A.

SIDE EFFECTS

Abdominal pain, alopecia, anorexia, arthralgia, asthenia, back pain, bone marrow suppression (e.g., anemia, leukopenia, neutropenia, thrombocytopenia), constipation, cough, diarrhea, dysgeusia, dyspnea, fatigue, fever, hematuria, nausea, peripheral neuropathy, and vomiting are most common. Serious side effects include bone marrow suppression (e.g., anemia, febrile neutropenia, neutropenia, thrombocytopenia), gastrointestinal symptoms, hypersensitivity reactions, increased toxicity in the elderly, infection, renal failure, respiratory disorders, and urinary disorders, including cystitis. Bone pain, cardiac arrhythmia, dehydration, dizziness, dyspepsia, dysuria, headache, hypotension, mucosal inflammation, muscle spasms, pain, peripheral edema, stomatitis, UTI, and weight loss have also occurred.

Post-Marketing:

Acute respiratory distress syndrome, gastritis, interstitial lung disease, interstitial pneumonia/pneumonitis, intestinal obstruction, and radiation recall hemorrhagic cystitis.

Overdose:

Exacerbation of adverse reactions such as bone marrow suppression and GI disorders.

ANTIDOTE

Keep physician informed of all side effects. Most will be treated symptomatically as indicated. Discontinue immediately if severe hypersensitivity reactions occur, and administer appropriate therapy. Neutropenia can be profound but may be treated with filgrastim (Neupogen, Zarxio). Severe thrombocytopenia may require platelet transfusions. Anemia may require packed cell transfusions or treatment with darbepoetin alfa (Aranesp) or epoetin alfa (Epogen). Severe GI toxicity may require cabazitaxel treatment delay or discontinuation. Discontinue cabazitaxel for Grade 3 or higher peripheral neuropathy or if adverse reactions continue after the dose adjustment to 20 mg/M^2. New or worsening pulmonary symptoms may require treatment and delay or discontinuation of cabazitaxel therapy. Interrupt or discontinue cabazitaxel for severe hemorrhagic cystitis. There is no specific antidote for overdose. Administer G-CSF as soon as possible and closely monitor chemistry, vital signs, and other functions. Resuscitate if indicated.

CAFFEINE AND SODIUM BENZOATE

(**KAF**-feen **SO**-dee-um **BEN**-zoh-ayt)
CNS stimulant
Respiratory stimulant adjunct
pH 6.5 to 8.5

USUAL DOSE

500 mg to 1 Gm. Maximum dose is 2.5 Gm/24 hr.

PEDIATRIC DOSE

8 mg/kg of body weight up to 500 mg every 4 hours. ***Do not use in neonates;*** see Precautions.

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

May be given undiluted.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

250 mg or fraction thereof over 1 minute. Extend rate of administration in neonate.

ACTIONS

A xanthine derivative and descending analeptic CNS stimulant. Small doses cause wakefulness and mental alertness. Larger doses stimulate the respiratory center and increase heart action. It is believed to constrict the intracranial blood vessels and lower intracranial pressure. Widely distributed throughout the body, metabolized in the liver, and excreted in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Rarely used. ■ Emergency treatment of respiratory depression due to CNS depressant overdose (e.g., alcohol, opiate analgesics) if naloxone (Narcan) is not available and treatment of emergency respiratory failure with electric shock.

Unlabeled uses:

Alleviate headaches after spinal cord puncture. ■ Treatment of vascular headaches (e.g., cluster, migraine) in combination with ergotamine.

CONTRAINDICATIONS

Acute myocardial infarction, hypersensitivity to drug or its components. Do not use in neonates; see Precautions.

PRECAUTIONS

Usually given IM; IV route is for emergencies only. ■ Do not use in neonates; sodium benzoate can displace bilirubin from its protein-binding sites and cause kernicterus, and/or cause “gasping syndrome.” Caffeine citrate or caffeine without sodium benzoate is preferred for IV dosage in neonates. These alternate IV formulations have been prepared and sterilized by the pharmacy. Caffeine citrate (Cafcit) is available commercially. ■ Most people have developed a tolerance level for caffeine because of daily ingestion of coffee or tea. ■ Death has occurred with IV administration. ■ Patients sensitive to other xanthines (e.g., aminophylline) may also be sensitive to caffeine. ■ Use caution in anxiety disorders, impaired hepatic function (half-life prolonged), hypertension, insomnia, seizure disorders, severe cardiac disease (tachycardia or extrasystoles may lead to heart failure). ■ Use as an analeptic considered ineffective by most clinicians. ■ May reactivate duodenal ulcers. ■ Doses over 1 Gm may increase depression in depressed individuals.

Monitor:

Observe frequently and monitor vital signs. ■ Monitor blood glucose; may cause hyperglycemia.

Maternal/Child:

Category C: safety not established in pregnancy or breast-feeding. Half-life may be increased in pregnant women. Excessive intake causes fetal loss, low birth weight, and premature delivery. ■ Half-life may be in excess of 100 hours in infants under 6 months of age due to immaturity of liver function.

DRUG/LAB INTERACTIONS

MAO inhibitors (e.g., selegiline) potentiate caffeine and can cause an acute hypertensive crisis. ■ May cause CNS excitation (cardiac arrhythmias, convulsions, insomnia, irritability, nervousness) with concurrent administration of **amphetamines** (e.g., dextroamphetamine), **caffeine-containing medications** (e.g., Excedrin), **caffeine-containing beverages, sympathomimetics** (e.g., epinephrine, norepinephrine, phenylpropanolamine). ■ Metabolism inhibited by **oral contraceptives, cimetidine, disulfiram, and fluoroquinolones;** a lower dose of caffeine may be indicated. ■ **Smoking** promotes elimination of caffeine; may decrease effectiveness. ■ Clearance of aminophylline reduced and serum levels increased when used concurrently with **caffeine.** ■ May **increase urine levels of VMA, catecholamines, 5-HIAA, and false-positive serum urate elevations.** May cause **false diagnosis of pheochromocytoma or neuroblastoma;** avoid caffeine when testing for these disorders.

SIDE EFFECTS

Cardiac irregularities, diarrhea, diuresis, excessive irritability, excitement, flushing, headache, hypertension (transient), insomnia, light-headedness, muscle twitching, nausea and vomiting, nervousness, palpitations, restlessness, scintillating scotoma (lightning flashes in the eyes), tachycardia, tinnitus, and death.

Neonatal:

Bradycardia, coarse tremors, hypertonicity alternating with hypotonicity, hypotension, intracranial hemorrhage, opisthotonic posturing, and severe acidosis.

ANTIDOTE

For major symptoms, discontinue drug and notify the physician. Maintain fluid and electrolyte balance, monitor ventilation and oxygenation. Diazepam, phenytoin, or phenobarbital will quiet CNS stimulation or seizures. Elimination may be increased with hemoperfusion. Resuscitate as necessary.

CAFFEINE CITRATE

(**KAF**-feen **SIT**-rayt)
Cafcit
CNS stimulant
Respiratory stimulant adjunct
pH 4.7

PEDIATRIC DOSE

Pretreatment:

Baseline studies may be indicated; see Precautions and Monitor.

The dose expressed as caffeine base is one-half the dose when expressed as caffeine citrate. The recommended loading dose and maintenance dose are listed in the following chart.

Guidelines for Loading and Maintenance Doses of Caffeine Citrate		
	Dose of Cafcit (volume)	**Dose Expressed as Caffeine Citrate**
Loading dose	1 mL/kg	20 mg/kg for 1 dose
Maintenance dose	0.25 mL/kg	5 mg/kg every 24 hours

Begin maintenance dose 24 hours after loading dose. Maintenance dose may be given IV or orally. Duration of treatment beyond 10 to 12 days has not been studied. See Precautions.

DOSE ADJUSTMENTS

May adjust maintenance dose using serum concentrations of caffeine. ■ To avoid toxicity in neonates with impaired renal or hepatic function, use with caution and monitor serum concentrations.

DILUTION

Both the IV and the oral doses are supplied in vials containing 60 mg/3 mL of caffeine citrate (30 mg/3 mL of caffeine base). Confirm that vial is for IV use. Withdraw calculated dose and dilute with sufficient D5W to administer at the recommended rate of administration.

Storage:

Store at CRT. Single-use vial. Discard any unused solution. Stable for 24 hours at room temperature when mixed with any of the solutions listed by the manufacturer in Compatibility.

COMPATIBILITY

Solution:

Manufacturer lists D5W; another source adds D5/¼NS, D5/¼NS with 20 mEq KCl/L.

Additive:

Manufacturer lists amino acid solution 8.5%, calcium gluconate 10%, D5W, dextrose 50%, dopamine 40 mg/mL diluted to 0.6 mg/mL with D5W, fentanyl 50 mcg/mL diluted to 10 mcg/mL with D5W, heparin sodium 1,000 units/mL diluted to 1 unit/mL with D5W, IV fat emulsion 20%.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Use of a syringe pump infuser is recommended.

Loading dose:

Infuse over 30 minutes.

Maintenance dose:

Infuse over 10 minutes.

ACTIONS

A bronchial smooth muscle relaxant, a CNS and cardiac stimulant, and a diuretic. Structurally related to other methylxanthines (e.g., theophylline and theobromine). Exact mechanism of action in apnea of prematurity is not known. Postulated mechanisms include stimulation of the respiratory center, increased minute ventilation, decreased threshold to hypercapnia, increased response to hypercapnia, increased skeletal muscle tone, decreased diaphragmatic fatigue, increased metabolic rate, increased oxygen consumption, blood vessel dilatation, central vessel vasoconstriction, and smooth muscle relaxation. Readily distributes into the brain. Caffeine levels in the CSF of preterm neonates approximate plasma levels. Metabolized in the liver by the cytochrome P_{450} system. Metabolism and elimination in the preterm neonate are much slower than in adults due to immature hepatic and/or renal function. Mean half-life and fraction excreted unchanged in the urine is inversely related to gestational/postconceptual age. In neonates, the half-life is approximately 3 to 4 days and the fraction excreted unchanged in the urine is approximately 86% (within 6 days). By 9 months of age, the metabolism of caffeine approximates that seen in adults (half-life is 5 hours and amount excreted unchanged is 1%). Interconversion between caffeine and theophylline has been reported in preterm neonates. After theophylline administration, caffeine levels are approximately 25% of theophylline levels. After caffeine administration, 3% to 5% of caffeine administered converts to theophylline.

INDICATIONS AND USES

Short-term treatment of apnea of prematurity in infants more than 28 but less than 33 weeks' gestational age. In one study apnea of prematurity was defined as having at least 6 apnea episodes of more than 20 seconds' duration in a 24-hour period with no other identifiable cause of apnea.

Unlabeled uses:

Prevention of postoperative apnea in former preterm infants.

CONTRAINDICATIONS

Hypersensitivity to any of its components.

PRECAUTIONS

Apnea of prematurity is a diagnosis of exclusion. Other causes of apnea (e.g., CNS disorders, primary lung disease, anemia, sepsis, metabolic disturbances, cardiovascular abnormalities, or obstructive apnea) should be ruled out or properly treated before initiating therapy with caffeine citrate. ■ Reports in the literature suggest a possible association between the use of methylxanthines and the development of necrotizing enterocolitis. Necrotizing enterocolitis, resulting in death in some cases, has been reported in neonates receiving caffeine citrate. ■ Is a CNS stimulant. Use with caution in infants with seizure disorders. ■ May increase heart rate, left ventricular output, and stroke volume. Use with caution in infants with cardiovascular disease. ■ Duration of treatment of apnea of prematurity in trials has been limited to 10 to 12 days. Safety and efficacy of therapy beyond this time have not been established. ■ Safety and efficacy for use in prophylactic treatment of sudden infant death syndrome (SIDS) or before extubation in mechanically ventilated infants have not been established. ■ Use with caution in infants with impaired renal or hepatic function; see Dose Adjustments and Monitor. ■ Patients sensitive to other xanthines (e.g., aminophylline) may also be sensitive to caffeine.

Monitor:

Obtain baseline serum caffeine levels in infants previously treated with theophylline because preterm infants metabolize theophylline to caffeine; see Actions. Levels should also be obtained in infants born to mothers who ingested caffeine before delivery, as caffeine readily crosses the placenta. Caffeine levels ranged from 8 to 40 mg/L in clinical trials. A therapeutic plasma concentration range has not been determined, but one source suggests 5 to 25 mcg/mL. Serious toxicity has been reported at levels exceeding 50 mg/L. Monitor levels periodically during treatment to avoid toxicity. Monitoring is especially important in infants with impaired renal or hepatic function; see Dose Adjustments. ■ Monitor serum glucose periodically. Hypoglycemia and hyperglycemia have been reported. ■ Monitor for S/S of necrotizing enterocolitis (e.g., gastric distension, vomiting, bloody stools). Screening stools for occult blood may be helpful in identifying early-onset necrotizing enterocolitis.

Patient Education:

Caregivers should be instructed to consult physician if infant continues to have apnea events and to not increase the dose of caffeine citrate without consulting a physician. ■ Contact physician at the first sign of lethargy or GI intolerance (e.g., abdominal distension, vomiting, or bloody stools). ■ Dose must be accurately measured, and any unused solution must be discarded.

Maternal/Child:

Category C: no controlled studies; benefits should outweigh risks. ■ Half-life is increased in pregnant women. ■ Half-life may be in excess of 100 hours in infants under 6 months of age due to immature liver function.

DRUG/LAB INTERACTIONS

Metabolized by the cytochrome P_{450} system. Lower caffeine doses may be required with coadministration of medications that **inhibit the P_{450} system,** decreasing the elimination of caffeine (e.g., cimetidine and ketoconazole]). Higher caffeine doses may be needed with coadministration of medications that **induce the P_{450} system,** increasing the elimination of caffeine (e.g., phenobarbital and phenytoin). ■ Interconversion between caffeine and **theophylline** has been reported. Concurrent use of these drugs is not recommended; see Actions.

SIDE EFFECTS

Cardiovascular effects (e.g., tachycardia, increased left ventricular output, and increased stroke volume), CNS stimulation (e.g., irritability, jitteriness, restlessness), GI effects (e.g., feeding intolerance, gastritis, increased gastric aspirate, and necrotizing enterocolitis), hyperglycemia, hypoglycemia, renal effects (e.g., increased urine output, increased CrCl, and increased sodium and calcium excretion).

Overdose:

Signs and symptoms of caffeine overdose in the preterm infant may include elevated BUN, elevated total leukocyte concentration, fever, fine tremor of extremities, hyperglycemia, hypertonia, insomnia, jitteriness, nonpurposeful jaw and lip movements, opisthotonos, seizures, tachypnea, tonic-clonic movements, or vomiting.

ANTIDOTE

Notify the physician of any side effects. Treatment of overdose is primarily symptomatic and supportive. Seizures may be treated with intravenous administration of diazepam or a barbiturate such as pentobarbital. Caffeine levels have been shown to decrease after exchange transfusions. Resuscitate as necessary.

CALASPARGASE PEGOL-mknl

(kal-**AS**-par-jase **PEG**-ol-mknl)
Asparlas
Antineoplastic agent
Enzyme

pH 7.3

USUAL DOSE

Pretreatment:

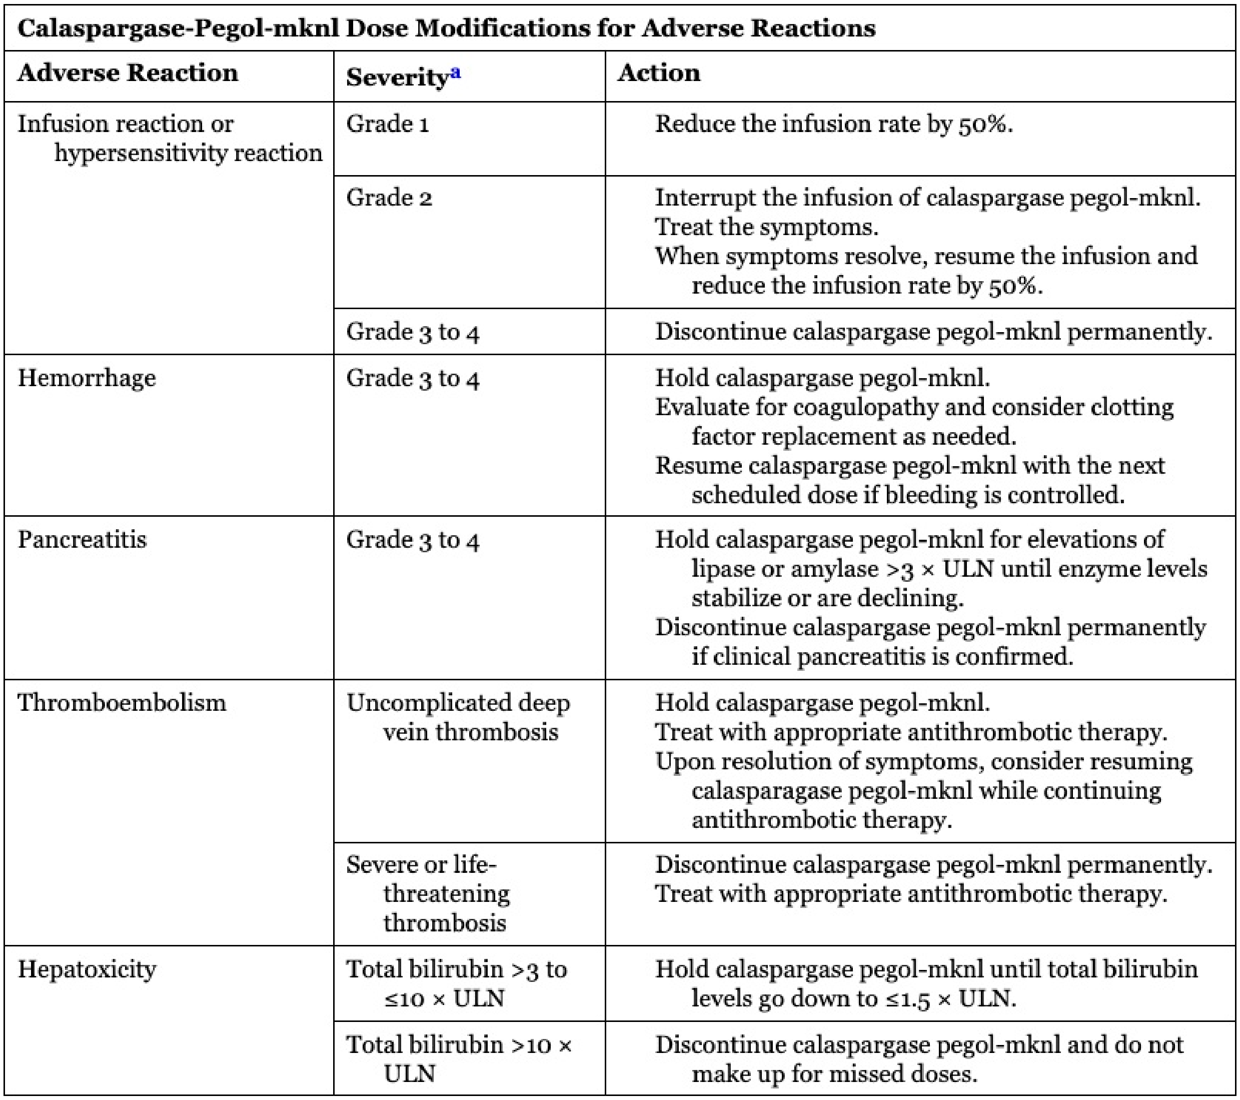
Verify pregnancy status in females of reproductive potential before starting treatment with calaspargase pegol-mknl.

Adult and pediatric patients (1 month to 21 years of age):

2,500 units/M^2 IV. Do not administer more frequently than every 21 days.

DOSE ADJUSTMENTS

See Monitor. If adverse reactions occur, modify treatment according to the following chart.



Calaspargase-Pegol-mknl Dose Modifications for Adverse Reactions

Adverse Reaction	**Severity**[a]	**Action**
Infusion reaction or hypersensitivity reaction	Grade 1	Reduce the infusion rate by 50%.
	Grade 2	Interrupt the infusion of calaspargase pegol-mknl. Treat the symptoms. When symptoms resolve, resume the infusion and reduce the infusion rate by 50%.
	Grade 3 to 4	Discontinue calaspargase pegol-mknl permanently.
Hemorrhage	Grade 3 to 4	Hold calaspargase pegol-mknl. Evaluate for coagulopathy and consider clotting factor replacement as needed. Resume calaspargase pegol-mknl with the next scheduled dose if bleeding is controlled.
Pancreatitis	Grade 3 to 4	Hold calaspargase pegol-mknl for elevations of lipase or amylase >3 × ULN until enzyme levels stabilize or are declining. Discontinue calaspargase pegol-mknl permanently if clinical pancreatitis is confirmed.
Thromboembolism	Uncomplicated deep vein thrombosis	Hold calaspargase pegol-mknl. Treat with appropriate antithrombotic therapy. Upon resolution of symptoms, consider resuming calasparagase pegol-mknl while continuing antithrombotic therapy.
	Severe or life-threatening thrombosis	Discontinue calaspargase pegol-mknl permanently. Treat with appropriate antithrombotic therapy.
Hepatoxicity	Total bilirubin >3 to ≤10 × ULN	Hold calaspargase pegol-mknl until total bilirubin levels go down to ≤1.5 × ULN.
	Total bilirubin >10 × ULN	Discontinue calaspargase pegol-mknl and do not make up for missed doses.

[a]Grade 1 is mild, Grade 2 is moderate, Grade 3 is severe, and Grade 4 is life-threatening.

DILUTION

Available as a clear, colorless solution in a single-dose vial containing 3,750 units/5 mL (750 units/mL). Dilute calaspargase pegol-mknl in 100 mL of NS or D5W using aseptic technique. ***Do not shake or vigorously agitate***. Discard any unused portion left in vials.

Storage:

Store unopened vials refrigerated at 2° to 8° C (36° to 46° F) in carton to protect from light. Do not shake or freeze. Unopened vials may be stored at RT for no more than 48 hours. The diluted solution may be stored up to 4 hours at RT or refrigerated at 2° to 8° C (36° to 46° F) for up to 24 hours. Protect from light. Discard the vial for any particulate matter, cloudiness, or discoloration. ***Do not administer*** if calaspargase pegol-mknl has been shaken or vigorously agitated, frozen, or stored at RT for more than 48 hours.

COMPATIBILITY

Manufacturer states, “Do not infuse other drugs through the same intravenous line during administration of calaspargase pegol-mknl.”

RATE OF ADMINISTRATION

A single dose as an infusion over 1 hour. After dilution, administer immediately into a running infusion of NS or D5W.

ACTIONS

Calaspargase pegol-mknl contains an asparagine-specific, enzyme-derived *Escherichia coli* as a conjugate of L-asparaginase and monomethoxypolyethylene glycol with a succinimidyl carbonate linker. L-asparaginase is an enzyme that catalyzes the conversion of the amino acid L-asparagine into aspartic acid and ammonia. The pharmacologic effect of calaspargase pegol-mknl is thought to be based on selective killing of leukemic cells due to depletion of plasma L-asparagine. Leukemic cells with low expression of asparagine synthetase have a reduced ability to synthesize L-asparagine and therefore depend on an exogenous source of L-asparagine for survival. The half-life is 16.1 days.

INDICATIONS AND USES

Treatment of acute lymphoblastic leukemia (ALL) in pediatric and young adult patients 1 month to 21 years of age. Administered as a component of a multiagent chemotherapeutic regimen.

CONTRAINDICATIONS

Patients with a history of any of the following: serious hypersensitivity reactions, including anaphylaxis, to pegylated L-asparaginase therapy; serious thrombosis during previous L-asparaginase therapy; serious pancreatitis during previous L-asparaginase therapy; serious hemorrhagic events during previous L-asparaginase therapy. ■ Patients with severe hepatic impairment.

PRECAUTIONS

Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, can occur. ■ Pancreatitis has been reported. ■ Serious thrombotic events, including sagittal sinus thrombosis, have been reported. ■ Hemorrhage associated with increased PT, PTT, and hypofibrinogenemia has occurred. ■ Hepatoxicity and abnormal liver function, including elevations of transaminase, elevations of bilirubin (direct and indirect), reduced serum albumin, and reduced plasma fibrinogen can occur. ■ As with all therapeutic proteins, there is the potential for immunogenicity.

Monitor:

Monitor patients at least weekly, with bilirubin, transaminases, glucose, and clinical examinations until recovery from cycle of therapy. ■ Monitor for S/S of hemorrhage or thrombosis. Obtain coagulation parameters, including PT, PTT, and fibrinogen, as indicated. ■ Evaluate patients with abdominal pain for evidence of pancreatitis. Assess serum amylase and/or lipase levels to confirm early signs of pancreatic inflammation. ■ Monitor patients for S/S of hypersensitivity reactions (e.g., angioedema, bronchospasm, dyspnea, erythema, eye swelling, hypotension, lip swelling, pruritus, and rash). Observe patient during and for at least 1 hour after infusion. ■ Evaluate bilirubin and transaminases at least weekly during cycles of treatment that include calaspargase pegol-mknl through at least 6 weeks after the last dose. ■ See Antidote.

Patient Education:

Promptly report all side effects, especially unusual bleeding or bruising, excessive thirst, frequent urination, hypersensitivity reactions (e.g., dizziness, feeling faint, flushing, hives, itching, nausea, pruritus, shortness of breath), jaundice, S/S of thrombosis (e.g., arm or leg swelling, chest pain, headache, shortness of breath), severe abdominal pain, or severe nausea or vomiting. ■ Advise females of reproductive potential to avoid becoming pregnant while receiving calaspargase pegol-mknl. Females should use effective contraceptive methods, including a barrier method, during treatment and for at least 3 months after the last dose. Use of oral contraceptives is not recommended.

Maternal/Child:

Based on animal studies, calaspargase pegol-mknl can cause fetal harm when administered to a pregnant woman. ■ Do not breast-feed while receiving calaspargase pegol-mknl and for 3 months after the last dose. ■ Safety and effectiveness of calaspargase pegol-mknl has been established in pediatric patients between 1 month and 17 years of age (no data for the age-group under 1 month of age).

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common adverse reactions were abnormal clotting studies, increased bilirubin, elevated transaminase, and pancreatitis. Other side effects include arrhythmia, cardiac failure, diarrhea, dyspnea, embolic and thrombotic events, fungal infection, hemorrhages, hypersensitivity, pneumonia, and sepsis.

ANTIDOTE

Notify physician of all side effects. Symptomatic and supportive treatment may be indicated. Discontinue in patients who experience a serious hypersensitivity reaction or a serious thrombotic event. Discontinue in patients if pancreatitis is suspected. If pancreatitis is confirmed, do not resume. If serious liver toxicity occurs, discontinue treatment and provide supportive care. Treat hypersensitivity reactions as indicated; may require epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Consider appropriate replacement therapy in patients with severe or symptomatic coagulopathy.

CALCITRIOL

(**kal**-si-**TRYE**-ole)
Calcijex
Vitamin D
pH 5.9 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Effectiveness of calcitriol therapy is dependent on adequate daily intake of calcium. The RDA of calcium in adults is 800 mg. Calcium supplementation or proper dietary measures must be initiated and maintained.

Hypocalcemia and/or secondary hyperparathyroidism:

Recommended initial dose, depending on the severity of hypocalcemia and/or secondary hyperparathyroidism, is 1 mcg (0.02 mcg/kg) to 2 mcg administered at each hemodialysis treatment (three times weekly, approximately every other day). Initial doses have ranged from 0.5 to 4 mcg three times weekly.

Information supplied by the manufacturer suggests that the relative dosing of paricalcitol to calcitriol is 4:1. When converting a patient from calcitriol to paricalcitol, the initial dose of paricalcitol should be four times greater than the patient's dose of calcitriol.

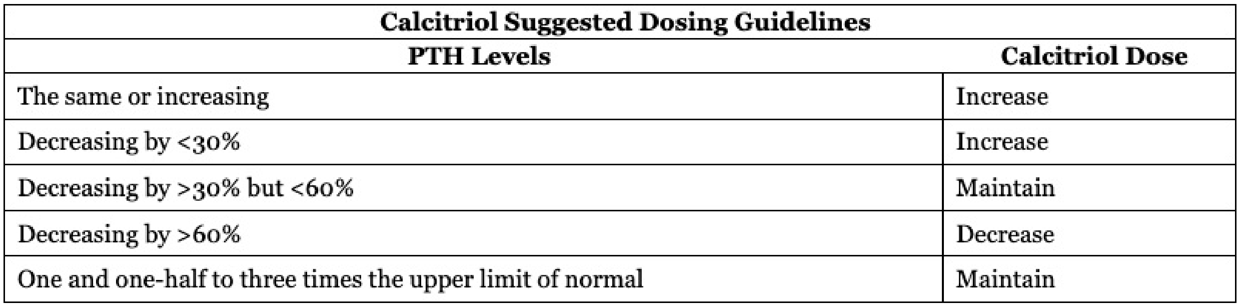
PEDIATRIC DOSE

Hypocalcemia in end-stage renal disease (ESRD) (unlabeled):

0.01 to 0.05 mcg/kg/dose given 3 times a week; see Maternal/Child. See all comments under Usual Dose.

DOSE ADJUSTMENTS

Adjust dosing based on patient response. Begin dosing at lower end of dose range in the elderly; see Elderly. If a satisfactory response is not observed, dose may be increased by 0.5 to 1 mcg at 2- to 4-week intervals. Monitor serum calcium, phosphorus, and calcium × phosphorus product (Ca × P) frequently during any dose adjustment period; see Monitor. ■ Discontinue therapy if elevated calcium level or a Ca × P product of greater than 70 is noted. Re-initiate therapy at a lower dose when parameters normalize. ■ Calcitriol dose may need to be reduced as the parathyroid hormone (PTH) levels decrease in response to therapy. The currently accepted target range for intact parathyroid hormone (iPTH) in chronic renal failure (CRF) patients is no more than 1.5 to 3 times the non-uremic upper limit of normal. Incremental dosing must be individualized and commensurate with PTH, serum calcium, and phosphorus levels. The following chart is a suggested approach to dose titration.



Calcitriol Suggested Dosing Guidelines

PTH Levels	Calcitriol Dose
The same or increasing	Increase
Decreasing by <30%	Increase
Decreasing by >30% but <60%	Maintain
Decreasing by >60%	Decrease
One and one-half to three times the upper limit of normal	Maintain

DILUTION

May be given undiluted. Available in 1-mcg/mL ampules.

Storage:

Store ampules at CRT. Protect from light. Calcitriol may be drawn up into a syringe up to 8 hours before administration but must be protected from direct sunlight.

COMPATIBILITY

Y-site:

D5W, NS, SWFI.

RATE OF ADMINISTRATION

Administer as a bolus dose into the venous line at the end of hemodialysis.

ACTIONS

The active form of vitamin D_3 (cholecalciferol). Must be metabolically activated in liver and kidney before it is fully active on its target tissues. In bone, acts with PTH to stimulate resorption of calcium. In kidneys, increases tubular reabsorption of calcium. Stimulates intestinal calcium transport and directly suppresses synthesis and release of PTH from the parathyroid gland. A vitamin D–resistant state may exist in uremic patients because of the failure of the kidney to adequately convert precursors to the active compound, calcitriol. Duration of action is 3 to 5 days.

INDICATIONS AND USES

Management of hypocalcemia in patients undergoing chronic renal dialysis. Has been shown to significantly reduce elevated PTH levels, which results in improvement in renal osteodystrophy.

CONTRAINDICATIONS

Patients with hypercalcemia or evidence of vitamin D toxicity.

PRECAUTIONS

Because calcitriol is the most potent form of vitamin D available, oral vitamin D supplements should be discontinued during treatment. ■ Dietary phosphorus should be restricted and a non–aluminum phosphate–binding compound (e.g., calcium acetate, sevelamer) should be administered to control serum phosphorus levels in patients undergoing dialysis.

Monitor:

Obtain baseline serum calcium, phosphorus, aluminum, albumin, and PTH assays. ■ Serum calcium levels should be corrected for serum albumin using the following equation: Corrected Ca = observed Ca + 0.8 × (normal albumin − observed albumin). For example: If serum calcium is 7 mg/dL and observed albumin is 2.5 Gm/dL, Corrected Ca = 7 + 0.8 × (4 − 2.5) = 8.2 mg/dL. All decisions regarding therapy should be based on corrected calcium values. ■ Monitor magnesium, alkaline phosphatase, and 24-hour urinary calcium and phosphorus periodically. ■ Criteria used to determine if calcitriol should be administered include serum calcium less than 11.5 mg/dL, Ca × P less than 70, serum albumin less than 60 mcg/L (within normal limits), and PTH more than 3 times the upper limit of normal. ■ Serum calcium, phosphorus, and the Ca × P product should be monitored twice weekly during dose titration. Once stable, decrease monitoring to once monthly. See Dose Adjustments. ■ PTH levels, once stable, should be monitored every 3 months. Adynamic bone lesions may develop if PTH levels are suppressed to abnormal levels. If PTH levels fall below the target range (1.5 to 3 times the upper limit of normal), the calcitriol dose should be reduced. Discontinuation may result in rebound effect. Therefore gradual titration downward to a new maintenance dose is recommended; see Dose Adjustments. ■ Overdosage of vitamin D is dangerous. May induce hypercalcemia and/or hypercalciuria. If clinically significant hypercalcemia develops, dose should be reduced or held. Chronic hypercalcemia can lead to generalized vascular calcification, nephrocalcinosis, and other soft-tissue calcification. The serum Ca × P product should not be allowed to exceed 70. Radiographic evaluation of suspect anatomic regions may be useful in early detection of this condition; see Side Effects and Antidote. ■ Use with caution in patients receiving digoxin. Hypercalcemia may precipitate cardiac arrhythmias; see Drug/Lab Interactions.

Patient Education:

Report symptoms of hypercalcemia promptly. Dose adjustment or treatment may be required. Strict adherence to dietary supplementation of calcium and restriction of phosphorus is required to ensure optimal effectiveness of therapy. Phosphate-binding compounds (e.g., calcium acetate [PhosLo]) may be needed to control serum phosphorus levels in patients with CRF, but excessive use of aluminum-containing products (e.g., aluminum hydroxide gel [Alternagel]) should be avoided. ■ Avoid use of unapproved nonprescription medications, including magnesium-containing antacids.

Maternal/Child:

Category C: safety for use in pregnancy not established. Benefits must outweigh risks. ■ Safety for use in breast-feeding not established. A decision should be made whether to discontinue nursing or to discontinue the drug. ■ Safety and effectiveness have been studied in a small number of pediatric patients, ages 13 to 18 years, with ESRD on hemodialysis. The mean weekly dose ranged from 1 to 1.4 mcg. Use in this study program appeared to be safe and effective. See package insert for study information.

Elderly:

Begin dosing at lower end of dose range. Consider age-related organ impairment, concomitant disease, and/or drug therapy; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Specific interaction studies have not been performed. ■ **Digoxin** toxicity is potentiated by hypercalcemia. Use caution when calcitriol is prescribed concomitantly with digoxin compounds. ■ **Phosphate or vitamin D–related compounds** should not be taken concomitantly with calcitriol. ■ **Magnesium-containing antacids** and calcitriol should not be used concomitantly. Hypermagnesemia may result.

SIDE EFFECTS

Overdose or chronic administration may lead to hypercalcemia, hypercalciuria, and hyperphosphatemia. High intake of calcium and phosphate concomitant with calcitriol therapy may lead to similar abnormalities. Signs and symptoms of vitamin D intoxication associated with hypercalcemia include ***Early:*** bone pain, constipation, dry mouth, headache, metallic taste, muscle pain, nausea, somnolence, vomiting, and weakness. ***Late:*** albuminuria, anorexia, cardiac arrhythmias, conjunctivitis (calcific), decreased libido, ectopic calcification, elevated AST and ALT, elevated BUN, hypercholesterolemia, hypertension, hyperthermia, nocturia, overt psychosis (rare), pain at injection site, pancreatitis, photophobia, polydipsia, polyuria, pruritus, rhinorrhea, and weight loss. Rare cases of hypersensitivity reactions, including anaphylaxis, have been reported.

ANTIDOTE

Notify physician of any side effects. Treatment of patients with clinically significant hypercalcemia (more than 1 mg/dL above the upper limit of normal range) consists of supportive measures, immediate dose reduction or interruption of therapy, initiation of a low-calcium diet, withdrawal of calcium supplements, patient mobilization, attention to fluid and electrolyte imbalances, assessment of electrocardiographic abnormalities (critical in patients receiving digoxin), and hemodialysis or peritoneal dialysis against a calcium-free dialysate, as warranted. Hypercalcemia usually resolves in 2 to 7 days. Monitor serum calcium levels frequently until calcium levels return to within normal limits. May re-initiate calcitriol therapy at a dose 0.5 mcg less than prior dose. See Dose Adjustments.

CALCIUM CHLORIDE

(**KAL**-see-um **KLOR**-eyed)
Electrolyte replenisher
Antihypocalcemic
Cardiotonic
Antihyperkalemic
Antihypermagnesemic
pH 5.5 to 7.5

USUAL DOSE

In a 10% solution, 10 mL (1 Gm) contains 13.6 mEq (272 mg) of calcium; 1 mL (100 mg), 1.36 mEq (27.2 mg). ***All doses based on a 10% solution.***

Hypocalcemic disorders (prophylaxis, treatment, electrolyte replacement, maintenance):

500 mg to 1 Gm at intervals of 1 to 3 days. Repeat doses may be required and are based on patient response or serum calcium levels. May be given as part of a TPN program.

Magnesium intoxication:

500 mg. Observe for signs of recovery before giving any additional calcium.

Hyperkalemia ECG disturbances of cardiac function:

100 mg to 1 Gm; titrate dose by monitoring ECG changes. AHA guidelines recommend 500 mg to 1 Gm. Repeat as needed.

Cardiac arrest or cardiotoxicity in the presence of hypocalcemia or hypermagnesemia.

Note: routine use of calcium, is not recommended due to lack of improved survival. 500-1000 mg as a rapid bolus.

Overdose of calcium channel blockers or beta-adrenergic blockers (unlabeled):

AHA guidelines recommend 500 mg to 1 Gm. May repeat as needed.

PEDIATRIC DOSE

Do not administer into a scalp vein in pediatric patients; see Precautions, Monitor, and Maternal/Child.

Hypocalcemic disorders:

0.027 to 0.05 mL/kg of body weight (2.7 to 5 mg/kg) of a 10% solution. Up to 10 mL (1 Gm)/day may be required. No data from clinical trials are available regarding repeat doses. Sources suggest repeat doses every 4 to 6 hours based on patient response or serum calcium levels.

Cardiac arrest in the prescence of hyperkalemia or hypocalcemia, hypermagnesemia or calicum channel antagonist toxcitiy:

20 mg/kg/dose (maximum dose 2000 mg).

DILUTION

For intermittent IV infusion, dilute to a maximum concentration of 20 mg/ml.

COMPATIBILITY

Calcium salts not generally mixed with carbonates, phosphates, sulfates, or tartrates. ***Extreme caution and a specific multistep process are required when calcium and phosphates are combined in parenteral nutrition solutions. Consult pharmacist.***

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

For IV administration only. Avoid rapid administration (do not exceed 100 mg/min, except in cardiac arrest. For intermittent IV infusion, infuse diluted solution over 1 hour or no greater than 45-90 mg/kg/hours (0.6 to 1.2 mEq/kg/hr). Administer via a central or deep vein is preferred; do not use samll hand or foot veins as severe necrosis and sloughing may occur.

ACTIONS

Calcium is a basic element prevalent in the human body. It affects bones, nerves, muscles, glands, cardiac and vascular tone, and normal coagulation of the blood. It is excreted in the urine and feces.

INDICATIONS AND USES

Calcium preparations other than calcium chloride are often preferred except in cardiac resuscitation or calcium channel blocker toxicity. ■ Increase plasma calcium levels in hypocalcemic disorders (e.g., tetany [neonatal, parathyroid deficiency], vitamin D deficiency, alkalosis, conditions associated with intestinal malabsorption). ■ Treat ECG disturbances caused by hyperkalemia. ■ Adjunctive therapy in sensitivity reactions (especially with urticaria), insect bites or stings (relieve muscle cramping), acute symptoms of lead colic, rickets, or osteomalacia. ■ Cardiac resuscitation only to treat hypocalcemia, hyperkalemia, hypermagnesemia or calcium-channel–blocker toxicity (verapamil, diltiazem), or after open heart surgery if epinephrine does not produce effective myocardial contractions. ■ Antidote for cardiac and respiratory depression of magnesium sulfate toxicity.

Unlabeled uses:

Treatment of arrhythmias and/or hypotension caused by an overdose of calcium channel blockers or beta-adrenergic blockers. ■ Prevention of hypotension caused by calcium channel blockers.

CONTRAINDICATIONS

Digitalized patients, hypercalcemia, ventricular fibrillation. Not recommended in the treatment of asystole and electromechanical dissociation.

PRECAUTIONS

Three times more potent than calcium gluconate. ■ For IV use only. ■ See Drug/Lab Interactions.

Monitor:

Confirm patency of vein; select a large vein and use a small needle to reduce vein irritation. Administration into a central or deep vein is preferred. Necrosis and sloughing will occur with IM or SC injection or extravasation. ■ Keep patient recumbent after injection to prevent postural hypotension. ■ Monitor vital signs carefully. ■ Monitor serum calcium levels as indicated. May cause hyperchloremic acidosis.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established. Use only when clearly needed. ■ Rarely used IV in pediatric patients. Use of a less irritating salt preferred because of small vein size.

DRUG/LAB INTERACTIONS

Will increase **digoxin** toxicity and may cause arrhythmias. If necessary, give small amounts very slowly. ■ Potentiated by **thiazide diuretics**; may cause hypercalcemia or calcium toxicity. ■ May reduce plasma levels of **atenolol**. ■ Can reduce neuromuscular paralysis and respiratory depression produced by **antibiotics such as kanamycin.** ■ Antagonizes **verapamil;** can reverse clinical effects. ■ May cause metabolic alkalosis and inhibit binding of potassium with **sodium polystyrene sulfonate.**

SIDE EFFECTS

Usual doses will produce a local burning sensation, moderate drop in BP, and peripheral vasodilation. May cause bradycardia; cardiac arrest; heat waves; metallic, calcium, or chalky taste; prolonged state of cardiac contraction; sense of oppression; or tingling sensation, especially with a too-rapid rate of administration.

Overdose:

Coma, intractable nausea and vomiting, lethargy, markedly elevated plasma calcium level, weakness, and sudden death.

ANTIDOTE

If extravasation occurs, immediately stop infusion and disconnect; gently aspirate extravasated solution. Do NOT flush the line. Initiate hyaluronidase antidote; remove needle/cannula; apply cold compresses; elevate extremity. Hyaluronidase: inject 1-1.7 ml intradermally or subctaneously as 5 separate 0.2-0.3 ml injections into area of extravasation (using 25 guage needle) at the leading edge in a clockwise manner. May also inject hyaluronidase through the catheter that caused the infiltration.

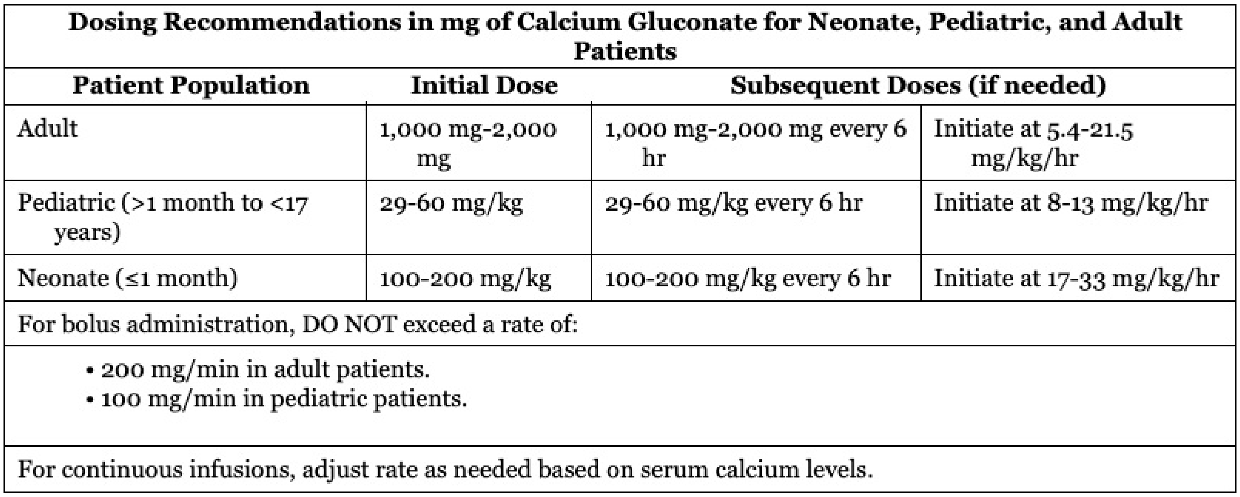
CALCIUM GLUCONATE

(**KAL**-see-um **GLOO**-koh-nayt)
Electrolyte replenisher
pH 6 to 8.2

USUAL DOSE

Individualize dose within the recommended ranges listed in the following chart based on severity of symptoms of hypocalcemia, the serum calcium level, and the acuity of onset of hypocalcemia.

All doses based on a 10% solution, which yields 10 Gm/100 mL or 100 mg/mL. (1 mL of calcium gluconate contains 9.3 mg [0.465 mEq] of elemental calcium.)



Dosing Recommendations in mg of Calcium Gluconate for Neonate, Pediatric, and Adult Patients

Patient Population	Initial Dose	Subsequent Doses (if needed)	
Adult	1,000 mg-2,000 mg	1,000 mg-2,000 mg every 6 hr	Initiate at 5.4-21.5 mg/kg/hr
Pediatric (>1 month to <17 years)	29-60 mg/kg	29-60 mg/kg every 6 hr	Initiate at 8-13 mg/kg/hr
Neonate (≤1 month)	100-200 mg/kg	100-200 mg/kg every 6 hr	Initiate at 17-33 mg/kg/hr
For bolus administration, DO NOT exceed a rate of:			
• 200 mg/min in adult patients. • 100 mg/min in pediatric patients.			
For continuous infusions, adjust rate as needed based on serum calcium levels.			

Calcium channel blocker overdose (unlabeled):

60 mg/kg/dose over 5 to 10 minutes (not to exceed 3,000 to 6,000 mg/dose); may repeat every 10 to 20 minutes for 3 to 4 additional doses. Alternatively, may initiate an infusion at 60 to 150 mg/kg/hr. Titrate to maintain adequate hemodynamic response.

Beta-blocker overdose (unlabeled):

60 mg/kg over 5 to 10 minutes followed by an infusion at 60 to 150 mg/kg/hr. Titrate to maintain adequate hemodynamic response.

PEDIATRIC AND NEONATAL DOSE

See Usual Dose, Precautions/Monitor, and Maternal/Child. ■ Do not administer into a scalp vein.

DOSE ADJUSTMENTS

For patients with renal impairment, initiate therapy at the lowest dose of the recommended dose range for all age-groups and monitor serum calcium every 4 hours. Accumulation may occur. ■ Dose selection for the elderly should start at the lowest dose of the recommended dose range, reflecting the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Supplied as a 10% solution in single-dose vials or pharmacy bulk packages. May be given by bolus IV administration or as a continuous IV infusion.

Bolus:

Dilute required dose in D5W or NS to a final concentration of 10 to 50 mg/mL before administration.

Continuous Infusion:

Dilute required dose in D5W or NS to a final concentration of 5.8 to 10 mg/mL before administration. Solution should appear clear and colorless to slightly yellow.

Storage:

Store at CRT. Do not freeze. Manufacturer recommends immediate administration of diluted solution. Discard unused portion in singe-dose vial immediately. Discard any unused portion of the pharmacy bulk package within 4 hours of initial entry into the vial. Supersaturated solutions may precipitate. If a precipitate is present, dissolve by warming the vial to 60° to 80° C (140° to 176° F) with occasional agitation until the solution becomes clear. Shake vigorously. Allow to cool to RT before administration.

COMPATIBILITY

Do not mix calcium gluconate with ceftriaxone. Concurrent use can lead to formation of ceftriaxone-calcium precipitates. Calcium-containing solutions and ceftriaxone may be administered sequentially in patients older than 28 days of age provided the infusion lines are thoroughly flushed between infusions with a **compatible** solution. ***Do not*** administer calcium gluconate and ceftriaxone simultaneously via a Y-site in any age-group. Calcium salts should not be mixed with phosphates, bicarbonates, or minocycline. ***Extreme caution and a specific multistep process are required when calcium and phosphates are combined in parenteral nutrition solutions. Consult pharmacist.***

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer via a secure IV line to avoid calcinosis cutis and tissue necrosis; see Precautions. ■ Rapid administration may cause vasodilation, decreased BP, bradycardia, cardiac arrhythmias, syncope, and cardiac arrest. May be administered by slow bolus administration or continuous infusion.

Bolus:

Administer slowly. ***Adult:*** DO NOT exceed a rate of 200 mg/min.

Pediatric patients (including neonates):

DO NOT exceed a rate of 100 mg/min.

Infusion:

Adjust rate as needed based on serum calcium levels. Bolus rates should not be exceeded.

In all situations, stop or slow infusion rate if patient complains of discomfort.

ACTIONS

IV administration of calcium gluconate increases serum ionized calcium level. Ionized calcium and gluconate are normal constituents of body fluids. Calcium in the body is distributed mainly in the skeleton (99%). Only 1% of the total body calcium is distributed within the extracellular fluids and soft tissues. About 50% of total serum calcium is in the ionized form and represents the biologically active part. Calcium plays a role in cardiac, neuromuscular, structural, and blood coagulation systems within the body. It crosses the placental barrier and is secreted in breast milk. It is excreted in the feces and urine.

INDICATIONS AND USES

Treatment of acute symptomatic hypocalcemia in pediatric and adult patients.

Unlabeled uses:

Treatment of calcium-channel–blocker overdose (e.g., diltiazem, verapamil). ■ Treatment of beta-blocker overdose (e.g., atenolol, metoprolol).

Limitation of Use:

Safety for long-term use has not been established.

CONTRAINDICATIONS

Hypercalcemia. ■ Neonates (28 days of age or younger) receiving ceftriaxone.

PRECAUTIONS

Has only one-third the potency of calcium chloride. ■ For IV use only. ■ Cardiac arrhythmias may occur if calcium and cardiac glycosides (e.g., digoxin) are administered together. Hypercalcemia increases the risk of digoxin toxicity. ■ Concomitant use of ceftriaxone and calcium gluconate is contraindicated in neonates due to cases of fatal outcomes in which a crystalline material was observed in the lungs and kidneys at autopsy after ceftriaxone and calcium were administered simultaneously through the same IV line. Concomitant administration can lead to the formation of ceftriaxone-calcium precipitates that may act as emboli, resulting in vascular spasm or infarction; see Contraindications and Compatibility. ■ IV administration and local trauma may result in calcinosis cutis. May occur with or without extravasation and is characterized by abnormal dermal deposits of calcium salts. Serious complications may include tissue necrosis, ulceration, and secondary infection. ■ Rapid administration may cause vasodilation, decreased BP, bradycardia, cardiac arrhythmias, syncope, and cardiac arrest. ■ Calcium gluconate contains aluminum (up to 400 mcg/L). In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive more than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation.

Monitor:

Confirm patency of vein; select a large vein and use a small needle to reduce vein irritation. ■ Monitor patient, vital signs, and ECG during administration. ■ Monitor serum calcium every 4 to 6 hours during intermittent (bolus) infusions and every 1 to 4 hours during continuous infusion. More frequent monitoring may be required in patients with renal impairment; see Dose Adjustments. ■ Monitor for calcinosis cutis; may clinically manifest as papules, plaques, or nodules that may be associated with erythema, swelling, or induration ■ Keep patient recumbent after injection to prevent postural hypotension.

Patient Education:

Promptly report pain or discomfort at injection site.

Maternal/Child:

Safety for use in pregnancy not established; benefits must outweigh risk. There are risks to the mother and the fetus associated with hypocalcemia in pregnancy. ■ Maternal hypocalcemia can result in an increased rate of spontaneous abortion, premature and dysfunctional labor, and possibly pre-eclampsia. ■ Infants born to mothers with hypocalcemia can have associated fetal and neonatal hyperparathyroidism, which in turn can cause fetal and neonatal skeletal demineralization, subperiosteal bone resorption, osteitis fibrosa cystica, and neonatal seizures. Infants born to mothers with hypocalcemia should be carefully monitored for signs of hypocalcemia or hypercalcemia, including neuromuscular irritability, apnea, cyanosis, and cardiac rhythm disorders. ■ Calcium is present in breast milk. There are no data on the effects of calcium gluconate administration on the breast-fed infant or milk production. Consider risk of infant exposure, benefits of breast-feeding to the infant, and benefits of treatment to the mother. ■ Safety and effectiveness of calcium gluconate have been established in pediatric patients for the treatment of acute, symptomatic hypocalcemia. ■ See Precautions and Contraindications.

Elderly:

Dose selection should start at the lowest dose of the recommended dose range; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Hypercalcemia increases the risk of **digoxin** toxicity and may cause arrhythmias. If necessary, give small amounts of calcium very slowly. ■ **Calcipotriene, estrogen, teriparatide, thiazide diuretics, vitamin A, and vitamin D** may cause hypercalcemia. Monitor calcium concentration in patients taking these drugs concurrently. ■ Administration of calcium may reduce the response to **calcium channel blockers**.

SIDE EFFECTS

The most common adverse reactions are calcification, calcinosis cutis, local soft tissue inflammation, and necrosis due to extravasation. Bradycardia, cardiac arrest, cardiac arrhythmias, hypotension, syncope, and vasodilation can occur with too-rapid rate of administration. Serious adverse reactions are described in Precautions.

Overdose:

Coma, confusion, depression, diminished ability to concentrate urine and diuresis, disorientation, fatigue, hallucinations, hypercalcemia, hypotonicity, seizures, weakness, and sudden death.

ANTIDOTE

If side effects occur, further dilution and decrease in the rate of administration may be necessary. If side effects persist, discontinue the drug and notify the physician. In an overdose situation, immediately discontinue administration and provide supportive treatments to restore intravascular volume and promote calcium excretion in the urine if necessary. Monitoring of fluid, electrolytes, and cardiac and respiratory status is imperative. If extravasation occurs or clinical manifestations of calcinosis cutis are noted, immediately discontinue IV administration at that site. For extravasation, inject affected area with hyaluronidase, using a 25-gauge needle. Apply dry, cold compresses and elevate extremity. Resuscitate as necessary.

CANGRELOR

(**KAN**-grel-or)
Kengreal
Antiplatelet agent

USUAL DOSE

Cangrelor:

30 mcg/kg as an IV ***bolus*** followed immediately by a 4 mcg/kg/min IV infusion. Initiate the bolus infusion prior to percutaneous coronary intervention (PCI). The maintenance infusion should ordinarily be continued for at least 2 hours or for the duration of PCI, whichever is longer.

Transitioning to oral $P2Y_{12}$ therapy:

To maintain platelet inhibition after discontinuation of cangrelor infusion, an oral $P2Y_{12}$ platelet inhibitor should be administered. Administer one as described below:

Ticagrelor (Brilinta):

180 mg at any time during cangrelor infusion or immediately after discontinuation.

Prasugrel (Effient):

60 mg immediately after discontinuation of cangrelor. Do not administer prasugrel before discontinuation of cangrelor.

Clopidogrel (Plavix):

600 mg immediately after discontinuation of cangrelor. Do not administer clopidogrel before discontinuation of cangrelor.

DOSE ADJUSTMENTS

No dose adjustments needed based on sex, age, renal status, or hepatic function. ■ The impact of weight on drug exposure is accounted for by the use of weight-based dosing.

DILUTION

Available as a sterile lyophilized powder in single-use 10-mL vials containing 50 mg cangrelor. Reconstitute each 50-mg vial with 5 mL of SWFI. Swirl gently until all material is dissolved. Avoid vigorous mixing. Allow any foam to settle. Ensure that the contents of the vial are fully dissolved and the reconstituted material is a clear, colorless to pale yellow solution. Before administration, each reconstituted vial must be further diluted with NS or D5W. Withdraw the contents from the reconstituted vial and add to a 250-mL bag of NS or D5W. Mix the bag thoroughly. Final concentration is 200 mcg/mL and should be sufficient for at least 2 hours of dosing. Patients 100 kg and over will require a minimum of 2 bags.

Storage:

Store vials of cangrelor at CRT (20° to 25° C [68° to 77° F]), with excursions between 15° and 30° C (59° and 86° F) permitted. Reconstituted cangrelor should be further diluted immediately. Cangrelor is stable at RT for 12 hours diluted in D5W and for 24 hours diluted in NS. Discard any unused portion of reconstituted solution remaining in the vial.

COMPATIBILITY

Manufacturer states, “Administer cangrelor via a dedicated IV line.”

RATE OF ADMINISTRATION

Administer cangrelor via a dedicated IV line.

Bolus:

Administer the bolus volume rapidly (less than 1 minute) from the diluted bag via manual IV push or pump. Ensure the bolus is completely administered before the start of PCI. Start the infusion immediately after administration of the bolus.

Infusion:

Administer at 4 mcg/kg/min. Continue for at least 2 hours or for the duration of PCI, whichever is longer.

ACTIONS

A direct $P2Y_{12}$ platelet receptor inhibitor that blocks adenosine diphosphate (ADP)–induced platelet activation and aggregation. It binds selectively and reversibly to the $P2Y_{12}$ receptor to prevent further signaling and platelet activation. When given according to the recommended regimen, platelet inhibition occurs within 2 minutes. Metabolism of cangrelor is independent of hepatic function and does not interfere with other drugs metabolized by hepatic enzymes. It is deactivated rapidly in the circulation by dephosphorylation to its primary metabolite, a nucleoside that has negligible antiplatelet activity. After discontinuation of the infusion, the antiplatelet effect decreases rapidly and platelet function returns to normal within 1 hour. The average elimination half-life is about 3 to 6 minutes. Excreted in urine and feces.

INDICATIONS AND USES

An adjunct to percutaneous coronary intervention (PCI) to reduce the risk of periprocedural myocardial infarction (MI), repeat coronary revascularization, and stent thrombosis (ST) in patients who have not been treated with a $P2Y_{12}$ platelet inhibitor and are not being given a glycoprotein IIb/IIIa inhibitor.

CONTRAINDICATIONS

Patients with significant active bleeding. ■ Known hypersensitivity (e.g., anaphylaxis) to cangrelor or any component of the product.

PRECAUTIONS

For IV use only. ■ Bleeding is the most common complication encountered during therapy. ■ Drugs that inhibit platelet $P2Y_{12}$ function, including cangrelor, increase the risk of bleeding. ■ Once cangrelor is discontinued, there is no antiplatelet effect after 1 hour. ■ Serious hypersensitivity reactions have been reported.

Monitor:

Monitor for S/S of bleeding. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, hypotension, pruritus, rash, urticaria, or wheezing).

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face).

Maternal/Child:

Use during pregnancy only if clearly needed. Life-sustaining therapy should not be withheld due to potential concerns regarding effects on the fetus. Use during labor and delivery may increase the risk for maternal bleeding and hemorrhage. Performance of neuraxial blockade procedures is not advised during use of cangrelor due to potential risk of spinal hematoma. When possible, discontinue cangrelor 1 hour before labor, delivery, or neuraxial blockade. ■ Data not available. Due to its short-half life, cangrelor exposure is expected to be very low in the breast-fed infant. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall difference in safety or effectiveness between older and younger patients has been observed.

DRUG/LAB INTERACTIONS

If **clopidogrel** or **prasugrel** is administered during cangrelor infusion, it will have no antiplatelet effect until the next dose is administered. Therefore **clopidogrel** and **prasugrel** should not be administered until cangrelor infusion is discontinued. ■ Administration of **ticagrelor** during cangrelor infusion does not attenuate the antiplatelet effect of ticagrelor. ■ Coadministration of cangrelor with unfractionated **heparin**, **aspirin**, and **nitroglycerin** was formally studied in healthy subjects, with no evidence of an effect on the pharmacokinetics and pharmacodynamics of cangrelor. ■ Cangrelor has been coadministered with bivalirudin, low-molecular-weight heparin, clopidogrel, prasugrel, and ticagrelor without clinically detectable interactions.

SIDE EFFECTS

The most common adverse reaction is bleeding.

Coronary artery dissection, coronary artery perforation, and dyspnea were the most frequent events leading to discontinuation of cangrelor. Serious cases of hypersensitivity, including angioedema, anaphylactic reactions, anaphylactic shock, bronchospasm, and stridor, have occurred. Decreased renal function was reported in a small number of patients with severe renal impairment (creatinine clearance less than 30 mL/min).

ANTIDOTE

There is no specific treatment to reverse the antiplatelet effect of cangrelor, but the effect is gone within 1 hour after discontinuation of the drug. Treat anaphylaxis immediately with oxygen, epinephrine, antihistamines, vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

CAPREOMYCIN BBW

(kap-ree-oh-**MYE**-sin)
Capastat
Antibacterial (antituberculosis)

USUAL DOSE

Pretreatment:

Pretesting and baseline studies indicated; see Monitor.

Capreomycin:

1 Gm daily, not to exceed 20 mg/kg/day. Give for 60 to 120 days, followed by 1 Gm two or three times weekly. Therapy for tuberculosis should be maintained for 12 to 24 months. Administered in combination with at least one other antituberculosis agent to which the patient's strain of tubercle bacilli is susceptible.

DOSE ADJUSTMENTS

The elderly and patients with reduced renal function should have dosage reduction based on CrCl using the guidelines in the following chart. These dosages are designed to achieve a mean steady-state capreomycin level of 10 mcg/mL. Elevation of BUN above 30 mg/dL or any other evidence of decreasing renal function warrants evaluation of patient. Dose reduction or discontinuation of therapy may be required.

Estimated Dosages to Attain Mean Steady-State Serum Capreomycin Concentration of 10 mcg/mL Based on CrCl

CrCl (mL/min)	Dose[a] (mg/kg) Based on Dosing Intervals		
	24 hr	48 hr	72 hr
0 mL/min	1.29 mg/kg	2.58 mg/kg	3.87 mg/kg
10 mL/min	2.43 mg/kg	4.87 mg/kg	7.30 mg/kg
20 mL/min	3.58 mg/kg	7.16 mg/kg	10.7 mg/kg
30 mL/min	4.72 mg/kg	9.45 mg/kg	14.2 mg/kg
40 mL/min	5.87 mg/kg	11.7 mg/kg	
50 mL/min	7.01 mg/kg	14.0 mg/kg	
60 mL/min	8.16 mg/kg		
80 mL/min	10.4 mg/kg[b]		
100 mL/min	12.7 mg/kg[b]		
110 mL/min	13.9 mg/kg[b]		

[a] Optional dosing intervals are given. Longer intervals are expected to provide greater peaks and lower trough serum levels than shorter intervals.

[b] See Usual Dose.

DILUTION

Reconstitute each 1-Gm vial with 2 mL of NS or SWFI. Allow 2 to 3 minutes for complete dissolution. Withdraw calculated dose and further dilute in 100 mL NS.

Filters:

No data available from manufacturer.

Storage:

Store at CRT before reconstitution. After reconstitution, stable for 24 hours if refrigerated.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over 60 minutes. Neuromuscular blockade or respiratory paralysis may occur following rapid intravenous infusion. See Precautions and Side Effects.

ACTIONS

A polypeptide antibiotic isolated from *Streptomyces capreolus*. Active against strains of *Mycobacterium tuberculosis*. Half-life is 4 to 6 hours in patients with normal renal function. Excreted primarily unchanged in urine. Small amounts excreted in bile. Crosses the placenta. Does not penetrate into CSF.

INDICATIONS AND USES

Used concomitantly with other appropriate antituberculosis agents to treat pulmonary infections caused by capreomycin-susceptible strains of *M. tuberculosis* when the primary agents (isoniazid, rifampin, ethambutol, aminosalicylic acid, and streptomycin) have been ineffective or cannot be used because of toxicity or the presence of resistant tubercle bacilli.

CONTRAINDICATIONS

Hypersensitivity to capreomycin.

PRECAUTIONS

Usually given IM; IV used in patients with limited muscle mass. ■ Sensitivity studies necessary to determine susceptibility of causative organism to capreomycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, capreomycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Use with caution in patients with pre-existing auditory impairment, dehydration, or renal insufficiency or when used concomitantly with other potentially ototoxic or nephrotoxic drugs (e.g., aminoglycosides [e.g., amikacin, gentamicin, tobramycin], colistin sulfate, polymyxin A, vancomycin). Must weigh risk of additional cranial nerve VIII (auditory and vestibular) damage or renal injury against benefit of therapy. ■ Coadministration with other parenteral antituberculosis agents (e.g., streptomycin) is not recommended. Toxicity is additive. ■ Renal injury, with tubular necrosis, elevation of BUN or SCr, and abnormal urinary sediment (casts, RBCs, WBCs), has been reported. Elderly patients, patients with abnormal renal function or dehydration, and patients receiving other nephrotoxic drugs are at increased risk for developing acute tubular necrosis. ■ Elevation of BUN above 30 mg/dL or other evidence of decreasing renal function warrants evaluation of patient. Dose reduction or discontinuation of drug may be necessary; see Dose Adjustments. Clinical significance of abnormal urine sediment and slight increase in BUN or SCr during long-term therapy is not known. ■ The peripheral neuromuscular blocking action seen with other polypeptide antibiotics (colistin sulfate, polymyxin A sulfate, paromomycin) and aminoglycosides (e.g., kanamycin, neomycin, streptomycin) has been reported with capreomycin. ■ Cross-resistance between capreomycin and kanamycin, neomycin and viomycin reported. No cross-resistance observed between capreomycin and aminosalicylic acid, cycloserine, ethambutol, ethionamide, isoniazid, and streptomycin. ■ Use with caution in patients with allergies (especially drug allergies).

Monitor:

Audiometric measurements and assessment of vestibular function should be performed before initiation of therapy and at regular intervals during treatment. ■ Obtain baseline SCr, BUN, liver function tests, and electrolytes before initiating therapy. Reduced dosage required for patients with impaired renal function; see Dose Adjustments. Weekly monitoring of renal function and periodic monitoring of electrolytes and liver function tests are recommended. ■ Obtain serum calcium, potassium, and magnesium levels frequently; hypocalcemia, hypokalemia, and hypomagnesemia may occur during therapy. ■ Monitor for S/S of hypersensitivity.

Patient Education:

Compliance with full course of therapy is imperative. Report any side effects promptly.

Maternal/Child:

Category C: safety for use during pregnancy and breast-feeding not established. Benefits must outweigh risks. Crosses the placenta. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to younger adults; however, dosing should be cautious; see Dose Adjustments. ■ May be at increased risk of toxicity because of age-related decrease in renal function; monitor renal function. ■ More likely to have impaired hearing at baseline. Initial and periodic audiometric measurement and assessment of vestibular function are recommended. See Precautions.

DRUG/LAB INTERACTIONS

Neuromuscular blockade of **nondepolarizing neuromuscular blocking agents** (e.g., vecuronium) may be enhanced with concurrent use of capreomycin because of synergistic effects and may be further enhanced by **ether or methoxyflurane anesthesia.** ■ Risk of neuromuscular blockade increased when administered concurrently or sequentially with **polymyxins or aminoglycosides** (e.g., kanamycin, neomycin, streptomycin); see Precautions. ■ Neuromuscular blockade antagonized by **neostigmine.** ■ Risk of ototoxicity, nephrotoxicity, and respiratory paralysis increased when administered concurrently or sequentially with **other potentially ototoxic or nephrotoxic medications** (e.g., aminoglycosides [e.g., amikacin, gentamicin, streptomycin, tobramycin], colistin sulfate, polymyxin A, vancomycin); see Precautions.

SIDE EFFECTS

Abnormal liver function tests; abnormal urine sediment; dizziness; electrolyte disturbances resembling Bartter’s syndrome, as well as hypocalcemia, hypokalemia, and hypomagnesemia; elevated BUN or SCr; eosinophilia; excessive bleeding; febrile reactions; hypersensitivity; leukocytosis; leukopenia; maculopapular skin rash; pain and induration at injection site; sterile abscesses; subclinical auditory loss (high-tone acuity); thrombocytopenia; tinnitus; toxic nephritis; urticaria; vertigo.

ANTIDOTE

Protect airway and support ventilation and perfusion. Hydrate patient to maintain urine output of 3 to 5 mL/kg/hr. Monitor fluid balance, electrolytes, renal function, vital signs, and blood gases; treat abnormalities as indicated. Hemodialysis may be useful. Resuscitate as necessary.

CARBOPLATIN BBW

(**KAR**-boh-plah-tin)
Antineoplastic (alkylating agent)
pH 5 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor. See Maternal/Child.

Before giving a dose in a cycle, it is recommended that platelets be above 100,000/mm^3 and neutrophils above 2,000/mm^3; see Dose Adjustments. The Calvert formula for carboplatin dosing based on pre-existing renal function and/or desired platelet nadir determines the patient's dose.

$$\text{Total dose (mg)} = (\text{Target AUC}) \times (\text{GFR} + 25)$$

Dose is calculated in milligrams, not mg/M^2. The ordering physician determines the target AUC (area under the curve) and supplies the required information on the GFR (glomerular filtration rate) or CrCl, as well as the desired response. The pharmacist calculates the correct dose. See package insert for additional information.

Initial treatment of advanced ovarian cancer in combination with cyclophosphamide:

Carboplatin 300 mg/M^2 plus cyclophosphamide 600 mg/M^2 on Day 1 every 4 weeks for 6 cycles or carboplatin dose targeted by Calvert equation to an AUC of 6 to 7 plus cyclophosphamide 600 mg/M^2 on Day 1 every 4 weeks.

Palliative treatment of recurrent ovarian cancer after prior chemotherapy:

As a single agent:

With normal renal function (CrCl greater than 60 mL/min), give 360 mg/M^2 on Day 1 every 4 weeks or, alternately, a dose targeted by Calvert equation to an AUC of 4 to 6 appears to provide an appropriate dose range in these patients.

DOSE ADJUSTMENTS

Single agent or combination therapy. Dose adjustment is based on nadir after prior dose according to the following chart.

Carboplatin Dose Based on Bone Marrow Suppression		
Platelets/mm^3	**Neutrophils/mm^3**	**Adjusted Dose (from Prior Course)**[a]
>100,000	>2,000	Increase to 125%
50,000-100,000	500-2,000	No adjustment
<50,000	<500	Decrease to 75%

[a] Percentages apply to carboplatin as a single agent or to both carboplatin and cyclophosphamide in combination.

Once the dose has been increased to 125% of the starting dose, no further dose increases are indicated. ■ With impaired renal function (CrCl 16 to 40 mL/min), give 200 mg/M^2; CrCl 41 to 59 mL/min, give 250 mg/M^2. Dose recommendation not available for patients with a CrCl less than 16 mL/min. ■ Bone marrow suppression is more severe in patients who have had prior therapy, especially with cisplatin and when carboplatin is used with other bone marrow–suppressing therapies or radiation, and may be more severe in the elderly. Reduced dose may be indicated. Monitor carefully and manage dose and timing to reduce additive effects.

DILUTION

Specific techniques required; see Precautions.

Available as a premixed solution (10 mg/mL) and as a lyophilized powder. Immediately before use, reconstitute each 10 mg of carboplatin lyophilized powder with 1 mL of SWFI, D5W, or NS (50 mg with 5 mL, 150 mg with 15 mL, 450 mg with 45 mL). All yield 10 mg/mL. Both preparations may be further diluted with NS or D5W to concentrations as low as 0.5 mg/mL. Do not use needles or IV tubing with aluminum parts to mix or administer; a precipitate will form and decrease potency. Best to mix lyophilized preparation immediately before use.

Storage:

Premixed solutions:

Stable to the date indicated on the package stored at CRT and protected from light. Multidose vials maintain microbial, chemical, and physical stability for up to 14 days at RT (25° C [77° F]) following multiple-needle entries. ***Lyophilized powder:*** Store unopened vials at CRT. Protect from light. Reconstituted solutions are stable for 8 hours at RT (25° C [77° F]). Discard 8 hours after dilution.

COMPATIBILITY

Forms a precipitate if in contact with aluminum (e.g., needles, syringes, catheters).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion over a minimum of 15 minutes. Extend administration time based on amount of diluent and patient condition.

ACTIONS

An alkylating agent. Better tolerated by patients, carboplatin causes less nausea and vomiting, less neurotoxicity, and less nephrotoxicity than cisplatin. Myelosuppression is generally reversible and manageable with antibiotics and transfusions. Produces interstrand DNA cross-links and is cell-cycle nonspecific. Not bound to plasma proteins. Half-life is 2.6 to 5.9 hours. Majority of carboplatin is excreted in the urine within 24 hours.

INDICATIONS AND USES

Initial treatment of advanced ovarian cancer in combination with other approved chemotherapeutic agents (e.g., cyclophosphamide). ■ Palliative treatment of recurrent ovarian cancer after prior chemotherapy, including patients treated with cisplatin.

Unlabeled uses:

Treatment of bladder cancer, non–small-cell lung cancer, and small-cell lung cancer.

CONTRAINDICATIONS

Hypersensitivity to cisplatin or other platinum-containing compounds or mannitol; severe bone marrow suppression; significant bleeding.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Bone marrow suppression is dose related and may be severe, resulting in infection and/or bleeding. Anemia may be cumulative and may require transfusion support. Bone marrow suppression increased in patients who have received prior therapy, especially regimens including cisplatin, and in patients with impaired kidney function. ■ Anaphylaxis has been reported and may occur within minutes of administration. ■ Risk of hypersensitivity increased in patients previously exposed to platinum therapy. Patients sensitive to other platinum compounds (e.g., cisplatin) may be sensitive to carboplatin; see Contraindications. ■ Peripheral neurotoxicity is uncommon, but risk may be increased in patients over 65 years of age and in patients previously treated with cisplatin. ■ Secondary malignancies, including acute nonlymphocytic leukemia, myeloproliferation syndrome, and carcinoma, have been reported in patients treated with alkylating agents. ■ See Drug/Lab Interactions.

Monitor:

BUN and SCr should be done before each dose. CrCl, WBC, platelet count, and hemoglobin are recommended before each dose and weekly thereafter. Platelet count recommended to be 100,000/mm^3 and neutrophils 2,000/mm^3 before a dose can be repeated; see Dose Adjustments. Anemia is frequent and cumulative. Transfusion is often indicated. ■ Excessive hydration or forced diuresis not required, but maintain adequate hydration and urinary output. ■ Nausea and vomiting are frequently severe but less than with cisplatin; generally last 24 hours. Prophylactic administration of antiemetics is indicated. Various protocols are used. ■ Observe for symptoms of hypersensitivity reactions during administration; epinephrine, corticosteroids, and antihistamines should be available. ■ Observe closely for symptoms of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Effective birth control recommended. Manufacturer provides a patient information booklet. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Significant hearing loss has been reported in pediatric patients; occurred with higher-than-recommended doses of carboplatin in combination with other ototoxic agents.

Elderly:

Neurotoxicity and myelotoxicity may be more severe. ■ Consider possibility of decreased renal function. ■ See Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

Nephrotoxicity and ototoxicity are additive when used with other **ototoxic or nephrotoxic agents** (e.g., acyclovir, aminoglycosides [e.g., gentamicin], cisplatin, rifampin, quinidine). Use with caution. ■ Bone marrow toxicity increased with other **antineoplastic agents, radiation therapy, and/or other agents that may cause blood dyscrasias** (e.g., anticonvulsants [e.g., phenytoin], cephalosporins, mycophenolate, rituximab). Dose adjustment of either or both drugs may be indicated. ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ See Dose Adjustments.

SIDE EFFECTS

Allergic reactions, including anaphylaxis, can occur during administration. Alopecia (rare), anemia, anorexia, bleeding, bone marrow suppression (usually reversible), bronchospasm, bruising, changes in taste, constipation, death, decreased serum electrolytes, decreased urine output, dehydration, diarrhea, erythema, fatigue, fever, hemolytic uremic syndrome (rare, cancer-associated), hypotension, infection, laboratory test abnormalities (alkaline phosphatase, aspartate aminotransferase [AST], BUN, SCr, total bilirubin), nausea and vomiting (severe), neutropenia, ototoxicity, peripheral neuropathies, pruritus, rash, stomatitis, thrombocytopenia, urticaria, visual disturbances, weakness.

ANTIDOTE

Notify physician of all side effects. Symptomatic and supportive treatment is indicated. Withhold carboplatin until myelosuppression has resolved. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines. There is no specific antidote.

CARFILZOMIB

(kar-**FILZ**-oh-mib)
Kyprolis
Antineoplastic
Proteasome inhibitor
pH 3.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies, blood pressure control, and fluid management indicated; see Monitor.

Hydration:

Hydration is indicated, especially in patients at high risk for renal toxicity and tumor lysis syndrome (TLS). Recommended hydration includes both oral fluids (30 mL/kg at least 48 hours before Cycle 1, Day 1) and intravenous fluids (250 to 500 mL of appropriate intravenous fluids before each dose in Cycle 1). Administer an additional 250 to 500 mL of intravenous fluid as needed after carfilzomib administration. Monitor fluid status and continue oral and/or intravenous hydration as needed in subsequent cycles.

Premedication:

To reduce the incidence and severity of infusion reactions, premedicate with ***dexamethasone.*** Dexamethasone dose depends on regimen used. Administer 4 mg IV or PO for 20/27 mg/M^2 monotherapy, 8 mg IV or PO for 20/56 mg/M^2 monotherapy, or the recommended dexamethasone dose if undergoing combination therapy. Administer at least 30 minutes before but no more than 4 hours before all doses of carfilzomib during Cycle 1. If infusion reactions occur during subsequent cycles, premedication with dexamethasone should be continued.

Thromboprophylaxis:

Thromboprophylaxis is recommended for patients being treated with a combination of carfilzomib with dexamethasone or of carfilzomib with lenalidomide plus dexamethasone. The regimen should be based on an assessment of the patient's underlying risks; see Precautions.

Infection prophylaxis:

Consider antiviral prophylaxis in patients being treated with carfilzomib to decrease the risk of herpes zoster reactivation.

Patients undergoing hemodialysis:

Administer carfilzomib after the hemodialysis procedure.

Carfilzomib:

Dose is calculated using actual body surface area (BSA) at baseline. Patients with a BSA greater than 2.2 M^2 should receive a dose based on a BSA of 2.2 M^2. Dose adjustments do not need to be made for weight changes less than or equal to 20%.

Combination therapy with lenalidomide and dexamethasone:

Administer over 10 minutes on 2 consecutive days each week for 3 weeks (Days 1, 2, 8, 9, 15, and 16), followed by a 12-day rest period (Days 17 to 28). Each 28-day period is considered 1 treatment cycle. The recommended starting dose of carfilzomib is 20 mg/M^2 in Cycle 1 on Days 1 and 2. If tolerated, escalate to a target dose of 27 mg/M^2 on Day 8 of Cycle 1. Beginning with Cycle 13, omit Days 8 and 9 doses of carfilzomib. Discontinue carfilzomib after Cycle 18. Administer lenalidomide 25 mg PO on Days 1 to 21 and dexamethasone 40 mg PO or IV on Days 1, 8, 15, and 22 of the 28-day cycles. A summary of this combination dosing regimen for carfilzomib is outlined in the following chart.

Carfilzomib Twice-Weekly (10-Minute Infusion) in Combination With Lenalidomide and Dexamethasone

[a]Carfilzomib is administered through Cycle 18; lenalidomide and dexamethasone continue thereafter.

Continue treatment until disease progression or unacceptable toxicity occurs. See prescribing information for lenalidomide and dexamethasone for other concomitant medications that may be required with those agents, such as anticoagulants or antacid prophylactic agents.

Combination therapy with dexamethasone:

Administer IV once weekly or twice weekly as a 30-minute infusion, depending on the regimen as described in the following sections.

Once-weekly 20/70 mg/M^2 regimen by 30-minute infusion:

Administer over 30 minutes once weekly for 3 weeks followed by a 13-day rest period. Each 28-day period is considered 1 treatment cycle. The recommended starting dose of carfilzomib is 20 mg/M^2 on Day 1 of Cycle 1. If tolerated, escalate to a target dose of 70 mg/M^2 on Days 8 and 15 of Cycle 1. Administer dexamethasone 40 mg PO or IV on Days 1, 8, and 15 of all cycles and on Day 22 of Cycles 1 to 9. A summary of this combination dosing regimen for carfilzomib is outlined in the following chart.

40 mg	—	—	40 mg	—	—	40 mg	—	—	—	—	—

Continue treatment until disease progression or unacceptable toxicity occurs. See prescribing information for dexamethasone.

Twice-weekly 20/56 mg/M^2 regimen by 30-minute infusion:

Administer over 30 minutes on 2 consecutive days each week for 3 weeks (Days 1, 2, 8, 9, 15, and 16), followed by a 12-day rest period (Days 17 to 28). Each 28-day period is considered 1 treatment cycle. The recommended starting dose of carfilzomib is 20 mg/M^2 on Days 1 and 2 of Cycle 1. If tolerated, escalate to a target dose of 56 mg/M^2 on Days 8, 9, 15, and 16 of Cycle 1. Administer dexamethasone 20 mg PO or IV on Days 1, 2, 8, 9, 15, 16, 22, and 23 of each 28-day cycle. A summary of this combination dosing regimen for carfilzomib is outlined in the following chart.

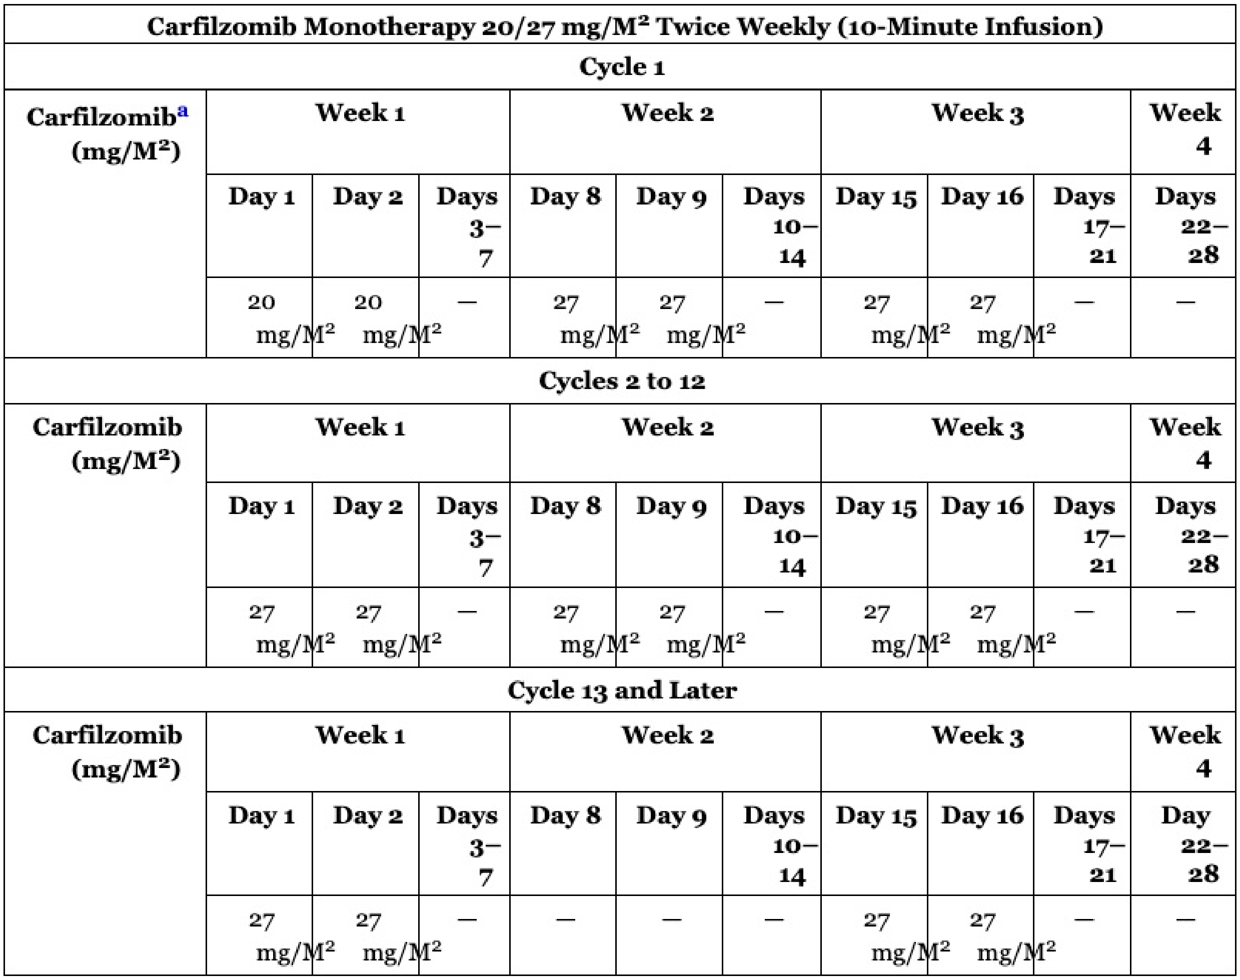
Continue treatment until disease progression or unacceptable toxicity occurs. See prescribing information for dexamethasone.

Monotherapy:

Administer twice weekly over 10 or 30 minutes, depending on the regimen as described in the following sections.

20/27 mg/M² twice-weekly regimen by 10-minute infusion:

Administer over 10 minutes on 2 consecutive days each week for 3 weeks (Days 1, 2, 8, 9, 15, and 16), followed by a 12-day rest period (Days 17 to 28). Each 28-day period is considered 1 treatment cycle. The recommended starting dose of carfilzomib is 20 mg/M² on Days 1 and 2 of Cycle 1. If tolerated, escalate to a target dose of 27 mg/M² on Days 8, 9, 15, and 16 of Cycle 1. Beginning with Cycle 13, omit Days 8 and 9 doses of carfilzomib. Continue treatment until disease progression or unacceptable toxicity occurs. A summary of this dosing regimen for carfilzomib is outlined in the following chart.



Carfilzomib Monotherapy 20/27 mg/M^2 Twice Weekly (10-Minute Infusion)										
Cycle 1										
Carfilzomib[a] (mg/M^2)	**Week 1**			**Week 2**			**Week 3**			**Week 4**

	56 mg/M^2	56 mg/M^2	—	—	—	—	56 mg/M^2	56 mg/M^2	—	—

[a] Dexamethasone premedication is required for each carfilzomib dose in Cycle 1.

DOSE ADJUSTMENTS

Dose is calculated using actual body surface area (BSA) at baseline. Patients with a BSA greater than 2.2 M^2 should receive a dose based on a BSA of 2.2 M^2. Dose adjustments do not need to be made for weight changes less than or equal to 20%. ■ Reduce the dose of carfilzomib by 25% in patients with mild hepatic impairment (total bilirubin 1 to 1.5 times the ULN and any AST or total bilirubin less than or equal to ULN and AST greater than ULN) or moderate hepatic impairment (total bilirubin greater than 1.5 to 3 times the ULN and any AST). Dosing recommendations cannot be made in patients with severe hepatic impairment; see Precautions. ■ No starting dose adjustment is required in patients with any degree of renal impairment. Administer carfilzomib after hemodialysis on dialysis days. ■ The pharmacokinetics of carfilzomib is not affected by age, gender, or race.

Recommended actions/dose modifications based on toxicities are in the following chart.

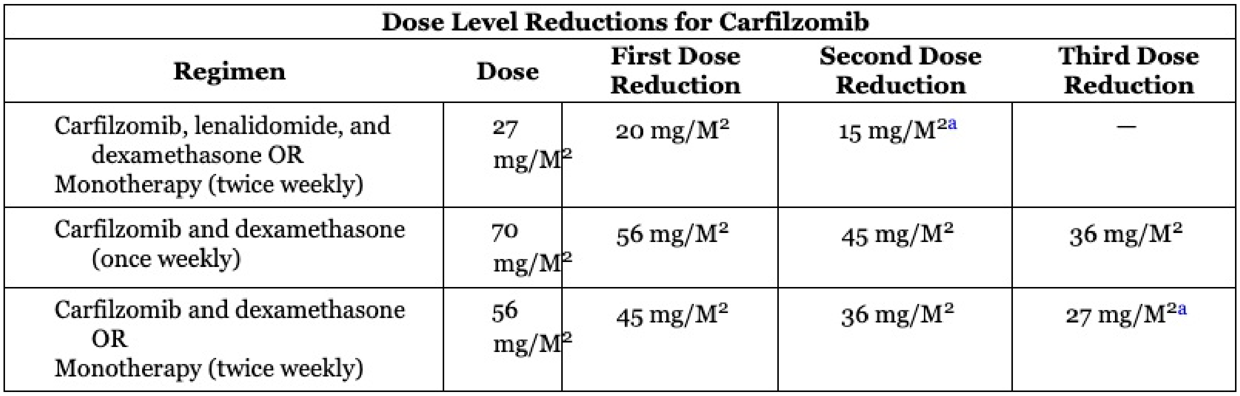
Dose Modifications for Toxicity During Carfilzomib Treatment	
Hematologic Toxicity	**Recommended Action**
Absolute neutrophil count <0.5×10^9/L (500 cells/mm^3)	• Withhold dose. • If recovered to ≥0.5×10^9/L, continue at same dose level. • For subsequent drops to <0.5×10^9/L, follow the same recommendations as above and consider 1 dose level reduction when restarting carfilzomib.[a]
Febrile neutropenia: ANC <0.5×10^9/L and an oral temperature more than 38.5° C (101.3° F) or two consecutive readings of more than 38° C (100.4° F) for 2 hours	• Withhold dose. • If ANC returns to baseline grade and fever resolves, resume at the same dose level.
Platelets <10×10^9/L (10,000 cells/mm^3) or evidence of bleeding with thrombocytopenia	• Withhold dose. • If recovered to ≥10×10^9/L and/or bleeding is controlled, continue at the same dose level. • For subsequent drops to <10×10^9/L, follow the same recommendations as above and consider 1 dose level reduction when restarting carfilzomib.[a]
Renal Toxicity	

Serum creatinine ≥2 × baseline OR
Creatinine clearance <15 mL/min OR
Creatinine clearance decreases to ≤50% of baseline OR
Need for dialysis
	• Withhold dose and continue monitoring renal function (serum creatinine or creatinine clearance).
	  • If attributable to carfilzomib, resume when renal function has recovered to within 25% of baseline; start at 1 dose level reduction.[a]
	  • If not attributable to carfilzomib, dosing may be resumed at the discretion of the physician.
	• For patients on dialysis receiving carfilzomib, the dose is to be administered after the dialysis procedure.

Other Nonhematologic Toxicity	
All other severe or life-threatening[b] non-hematologic toxicities	• Withhold until resolved or returned to baseline. • Consider restarting the next scheduled treatment at 1 dose level reduction.[a]

[a] See the following chart for dose level reductions.

[b] CTCAE Grades 3 and 4.



Dose Level Reductions for Carfilzomib				
Regimen	Dose	First Dose Reduction	Second Dose Reduction	Third Dose Reduction
Carfilzomib, lenalidomide, and dexamethasone OR Monotherapy (twice weekly)	27 mg/M^2	20 mg/M^2	15 mg/M^2[a]	—
Carfilzomib and dexamethasone (once weekly)	70 mg/M^2	56 mg/M^2	45 mg/M^2	36 mg/M^2
Carfilzomib and dexamethasone OR Monotherapy (twice weekly)	56 mg/M^2	45 mg/M^2	36 mg/M^2	27 mg/M^2[a]

NOTE: Infusion times remain unchanged during dose reduction(s).

[a] If toxicity persists, discontinue carfilzomib treatment.

DILUTION

Specific techniques required; see Precautions. There are no data to support the use of closed-system transfer devices with carfilzomib. Available in 10-, 30-, and 60-mg single-use vials. Remove from refrigerator just before use. Reconstitute each vial using a 21-gauge or larger gauge needle by slowly injecting 5 mL SWFI (for the 10-mg vial), 15 mL SWFI (for the 30-mg vial), or 29 mL SWFI (for the 60-mg vial) into the vial. Direct the SWFI onto the inside wall of the vial to minimize foaming. Gently swirl and/or invert vial slowly for about 1 minute or until complete dissolution occurs. ***Do not shake.*** If foaming occurs, allow solution to rest in vial for about 5 minutes, until foaming subsides. Final concentration of reconstituted solution is 2 mg/mL. May withdraw reconstituted calculated dose from vial and administer without further dilution. Alternately, may withdraw calculated dose using a 21-gauge or larger gauge needle and dilute in 50 or 100 mL of D5W and administer as an infusion; see Rate of Administration.

Filters:

No data available from manufacturer.

Storage:

Unopened vials should be refrigerated at 2° to 8° C (36° to 46° F). Retain in original package to protect from light. Both the reconstituted solution stored in the vial or a syringe and the solution diluted in D5W are stable for 24 hours when refrigerated and for 4 hours when stored at RT. Total time from reconstitution to administration should not exceed 24 hours. Discard any unused portion.

COMPATIBILITY

Manufacturer states, "Do not mix with or administer as an infusion with other medicinal products."

RATE OF ADMINISTRATION

Administer as an IV infusion over 10 or 30 minutes depending on the carfilzomib regimen. **Do not** administer as a bolus. Flush line with NS or D5W immediately before and after carfilzomib administration.

ACTIONS

Carfilzomib is a proteasome inhibitor that irreversibly binds to specific sites on the 20S proteasome. Has antiproliferative and pro-apoptotic activities in vitro in solid and in hematologic tumor cells. Actions result in cell-cycle arrest and apoptosis. Highly protein bound. Extensively metabolized via peptidase and epoxide hydrolase activities. Metabolites have no known biologic activity. Has a half-life of ≤1 hour on Day 1 of Cycle 1. The pathways of carfilzomib elimination have not been characterized in humans. Partially excreted in the urine as metabolites.

INDICATIONS AND USES

Treatment of patients with relapsed or refractory multiple myeloma who have received one to three prior lines of therapy. Given in combination with dexamethasone or with lenalidomide plus dexamethasone. ■ As a single agent for treatment of patients with relapsed or refractory multiple myeloma who have received one or more lines of therapy.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A. ■ For IV use only; see Rate of Administration. ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ New onset or worsening of pre-existing cardiac failure (e.g., congestive heart failure, pulmonary edema, decreased ejection fraction), restrictive cardiomyopathy, myocardial ischemia, and myocardial infarction, including fatalities, have been reported and have occurred throughout the course of therapy. Death from cardiac arrest has occurred within a day of administration. Patients with New York Heart Association Class III and IV heart failure, recent myocardial infarction, conduction abnormalities, angina, or arrhythmias uncontrolled by medications may be at greater risk for cardiac complications and were not eligible for the clinical trials. ■ Renal adverse events, including renal impairment and acute renal failure, have been reported. Fatalities have occurred. Acute renal failure was reported more frequently in patients with advanced relapsed and refractory multiple myeloma who received carfilzomib monotherapy. The risk of fatal renal failure was greater in patients with existing renal impairment. ■ Acute respiratory distress syndrome (ARDS), acute respiratory failure, and acute diffuse infiltrative pulmonary disease such as pneumonitis and interstitial lung disease have been reported. Fatalities have occurred. ■ Pulmonary arterial hypertension has been reported. ■ Dyspnea was reported in close to one-third of patients in clinical trials. ■ Hypertension, including hypertensive crisis and hypertensive emergency, has been observed. Some events have been fatal. It is recommended to control hypertension before starting carfilzomib. ■ Venous thromboembolic events (including deep venous thrombosis [DVT] and pulmonary embolism [PE]) have been observed. Incidence of events was higher with combination therapy. Thromboprophylaxis is recommended for patients receiving combination therapy and should be based on an assessment of the patient's underlying risk factors, treatment regimen, and clinical status. ■ Infusion reactions, including life-threatening reactions, can occur immediately after or up to 24 hours after administration of carfilzomib. Premedication with dexamethasone may reduce the incidence and severity of reaction. ■ Fatal or serious cases of hemorrhage have been reported. Events have included epistaxis and GI, pulmonary, and intracranial hemorrhage. Bleeding may be spontaneous and has occurred in patients with either low or normal platelet counts. ■ Cases of TLS, some with fatal outcome, have been reported. Patients with multiple myeloma and a high tumor burden may be at increased risk for developing TLS. ■ Cases of hepatic failure have been reported. Fatalities have occurred. Carfilzomib may cause elevations of serum transaminases and bilirubin. Safety, efficacy, and pharmacokinetics have not been studied in patients with severe hepatic impairment (bilirubin greater than 3 times the ULN and any AST). The incidence of serious adverse events was higher in patients with any degree of hepatic impairment. Use caution. ■ Cases of thrombotic microangiopathy, including thrombotic thrombocytopenic purpura/hemolytic uremic syndrome (TTP/HUS), have been reported. Some cases have been fatal. ■ Cases of posterior reversible encephalopathy syndrome (PRES) have been reported. ■ See Dose Adjustments.

Monitor:

Obtain baseline CBC with differential and platelets. Obtain baseline AST, ALT, bilirubin, and SCr. ■ Monitor serum transaminases and bilirubin frequently regardless of baseline values, and modify dose based on toxicity; see Dose Adjustments. ■ Monitor fluid status, CBC, SCr (or estimated CrCl), and serum potassium closely throughout treatment. Avoid fluid overload, especially in patients at risk for cardiac failure. ■ Monitor for cardiac complications (e.g., cardiac failure, pulmonary edema, decrease in ejection fraction, ischemia) and treat promptly. Patients with pre-existing cardiovascular disease may be at greater risk for cardiac complications. A comprehensive medical assessment (including BP control and fluid management) should be performed before starting treatment. Close follow-up is required during therapy. ■ Monitor for S/S of pulmonary hypertension. Evaluate with cardiac imaging and/or other tests as indicated. ■ Monitor pulmonary function with new or worsening pulmonary symptoms (e.g., dyspnea). Evaluate dyspnea to exclude cardiopulmonary conditions, including cardiac failure and other types of pulmonary syndromes or toxicity (e.g., ARDS, pneumonitis). ■ Monitor BP regularly. ■ Monitor for S/S of DVT and/or PE (e.g., swelling, pain, and/or warmth of extremity, shortness of breath). ■ Monitor for S/S of an infusion reaction (e.g., angina, arthralgia, chest tightness, chills, facial edema, facial flushing, fever, hypotension, myalgia, shortness of breath, syncope, vomiting, and weakness). ■ Monitor for S/S of blood loss. ■ Monitor uric acid levels as indicated. Prevention and treatment of hyperuricemia due to TLS may be accomplished with adequate hydration and, if necessary, with uric acid–lowering drugs (e.g., allopurinol). ■ Carfilzomib causes thrombocytopenia. Monitor platelet counts frequently. Nadir occurs between Day 8 and Day 15 of each 28-day cycle. Recovery to baseline should occur by the start of the next 28-day cycle. Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor for S/S of TTP/HUS. The safety of re-initiating carfilzomib therapy in patients previously experiencing TTP/HUS is not known. ■ Monitor for S/S of PRES (e.g., altered consciousness, blindness, confusion, headache, lethargy, seizure, and other visual and neurologic disturbances along with hypertension). Diagnosis is confirmed by neuroradiologic imaging (MRI). The safety of re-initiating carfilzomib therapy in patients previously experiencing PRES is not known. ■ See Dose Adjustments.

Patient Education:

Avoid pregnancy. Female patients of reproductive potential must use effective contraceptive measures during treatment with carfilzomib and for at least 6 months after completion of therapy. Patients using oral contraceptives or a hormonal method of contraception associated with a risk of thrombosis should consider an alternative method of effective contraception during treatment with carfilzomib in combination with dexamethasone or with lenalidomide plus dexamethasone. ■ Male patients of reproductive potential should avoid fathering a child while being treated with carfilzomib and for at least 90 days after completion of therapy. ■ Promptly report S/S of an infusion reaction. ■ Promptly report symptoms such as bleeding, bruising, chest pain, chills, confusion, cough, dyspnea, fever, headaches, jaundice, rigors, seizures, shortness of breath, swelling of the feet or legs, visual loss, or weakness. ■ May cause fatigue, dizziness, fainting, and/or a drop in blood pressure. Use caution in tasks that require alertness. ■ Avoid dehydration. Seek medical advice if dizziness, light-headedness, or fainting spells are experienced. ■ Review all medications with a physician or pharmacist. ■ See Appendix D.

Maternal/Child:

Based on its mechanism of action, can cause fetal harm when administered to a pregnant woman. ■ Do not breast-feed during treatment with carfilzomib and for 2 weeks after treatment. ■ Safety and effectiveness of carfilzomib in pediatric patients have not been established.

Elderly:

Differences in efficacy between patients under 65 years of age and patients 65 years of age and older have not been identified. The incidence of serious adverse events is higher in patients 65 years of age or older. The risk of cardiac failure is increased in patients 75 years of age or older.

DRUG/LAB INTERACTIONS

Carfilzomib is primarily metabolized via peptidase and epoxide hydrolase activities and, as a result, is unlikely to be affected by concomitant administration of cytochrome P_{450} inhibitors and inducers. ■ Because of IV administration and extensive metabolism, carfilzomib should not be affected by P-gp inhibitors or inducers. ■ Carfilzomib is not expected to influence exposure of other drugs. ■ Carfilzomib in combination with melphalan and prednisone is not indicated for transplant-ineligible patients with newly diagnosed multiple myeloma due to increased fatalities and serious toxicities.

SIDE EFFECTS

The most commonly reported adverse reactions occurring in at least 20% of patients treated with ***carfilzomib in monotherapy*** are anemia, cough, diarrhea, dyspnea, fatigue, fever, headache, nausea, peripheral edema, and thrombocytopenia. The most common serious adverse reactions are acute renal failure, anemia, congestive heart failure, dyspnea, fever, hypercalcemia, and pneumonia. The most commonly reported adverse reactions occurring in at least 20% of patients treated with ***carfilzomib combination therapy*** are anemia, cough, diarrhea, dyspnea, fatigue, fever, hypokalemia, insomnia, muscle spasm, neutropenia, thrombocytopenia, and upper respiratory tract infection. The most common serious adverse reactions are fever, pneumonia, pulmonary embolism, and respiratory tract infection. Additional adverse reactions reported in at least 10% of patients receiving carfilzomib as either monotherapy or combination therapy include anorexia; arthralgia; asthenia; back pain; bronchitis; chills; constipation; decreased absolute neutrophil count, lymphocytes, and total white blood cell count; dizziness; elevated aspartate aminotransferase (AST); elevated serum creatinine; epistaxis; hyperglycemia; hyperkalemia; hypertension; hyperuricemia; hypocalcemia; hypoesthesia; hypomagnesemia; hyponatremia; hypophosphatemia; insomnia; nasopharyngitis; pain; peripheral neuropathy; pneumonia; rash; tinnitus; venous embolic and thrombotic events; and vomiting. Serious but less commonly reported adverse reactions include acute kidney injury, cardiac toxicities (cardiac arrest, congestive heart failure, myocardial ischemia), hemorrhage, hepatic toxicity and hepatic failure, infusion reactions, PRES, pulmonary toxicity, pulmonary hypertension, TTP/HUS, and TLS. Several other adverse reactions have been reported; see manufacturer's prescribing information.

Post-Marketing:

GI perforation, hemolytic uremic syndrome (HUS), pericarditis.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. If signs of an infusion reaction occur, slow or interrupt the infusion and treat appropriately. Monitor patients carefully until symptoms resolve. Discontinue immediately for a serious hypersensitivity reaction. Discontinue for any drug-induced pulmonary toxicity. Discontinue therapy if TTP/HUS or PRES is suspected. Withhold for Grade 3 or 4 cardiac adverse event until recovery or return to baseline, and consider whether to restart at 1 dose level reduction based on benefit/risk assessment. Withhold for pulmonary hypertension or Grade 3 or 4 dyspnea until resolved or returned to baseline, and consider whether to restart carfilzomib based on a benefit/risk assessment. Withhold therapy if hypertension cannot be adequately controlled. Evaluate and consider whether to restart carfilzomib based on a risk/benefit assessment. There is no specific antidote for carfilzomib. In the event of an overdose or with the occurrence of a serious adverse reaction, discontinue carfilzomib; see Dose Adjustments. Notify the physician and provide supportive care as indicated. Administration of blood products may be indicated. Treat hypersensitivity reactions with epinephrine, antihistamines, corticosteroids, bronchodilators, and oxygen. Resuscitate as indicated.

CARMUSTINE (BCNU) BBW

(kar-**MUS**-teen)
BiCNU
Antineoplastic (alkylating agent/nitrosourea)
pH 5.6 to 6

USUAL DOSE

Pretreatment:

Verify nonpregnancy status. Baseline testing and studies required; see Monitor.

Premedication:

Administration of antiemetics is recommended.

Carmustine:

Initial dose as a single agent in previously untreated patients is 150 to 200 mg/M^2. May be given as a single dose, or one-half of the calculated dose may be given initially and repeated the next day. Repeat every 6 weeks if bone marrow is sufficiently recovered. Repeat course should not be administered until leukocytes are above 4,000/mm^3, platelets are above 100,000/mm^3, and ANC is above 1,000/mm^3. Subsequent doses should be adjusted according to hematologic response of previous dose (see Dose Adjustments).

DOSE ADJUSTMENTS

Bone marrow toxicity can be delayed and cumulative. Dose adjustments must be considered ***based on the nadir blood counts from the prior dose*** according to the following chart. Do not administer a repeat course of carmustine until blood counts recover.

Carmustine Dose Adjustment Based on Bone Marrow Suppression

Nadir After Prior Dose		Percentage of Prior Dose to Be Given
Leukocytes/mm^3	Platelets/mm^3	%
≥4,000	≥100,000	100%
3,000-3,999	75,000-99,999	100%
2,000-2,999	25,000-74,999	70%
<2,000	<25,000	50%

Lower doses accordingly when carmustine is used in combination with other myelosuppressive drugs or in patients with depleted bone marrow reserve. ■ Do not administer carmustine to patients with compromised renal function. Carmustine should be discontinued in patients with a CrCl less than 10 mL/min. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see Elderly.

DILUTION

Specific techniques required; see Precautions.

Initially dilute 100-mg vial with supplied sterile diluent (3 mL of dehydrated alcohol injection). Further dilute with 27 mL of SWFI. Each mL will contain 3.3 mg carmustine. The reconstituted solution should be a clear, colorless to yellowish solution. Withdraw desired dose and further dilute in up to 500 mL of NS or D5W and give as an infusion. A concentration of 0.2 mg/mL is desired. Use glass or polypropylene containers.

Filters:

No significant loss of potency with any size cellular ester membrane filter when reconstituted or diluted as recommended.

Storage:

Must be protected from light in all forms. Store unopened vials of the dry drug (carmustine) and supplied diluent in refrigerator (2° to 8° C [35° to 46° F]). After reconstitution as directed, carmustine is stable for 24 hours under refrigeration. Reconstituted vials should be examined for crystal formation before use. If crystals have formed, they may be redissolved by warming the vial to RT with agitation. After reconstitution and after further dilution to a concentration of 0.2 mg/mL in NS or D5W, may be stored at RT but must be used within 8 hours. Fully diluted solution may also be stored under refrigeration for 24 hours and an additional 6 hours at RT. Temperatures above 30.5° C (86.9° F) will cause liquefaction of the drug powder; discard immediately. Product is intended for single use. Discard any unused solution.

COMPATIBILITY

Manufacturer lists as **incompatible** with polyvinyl chloride infusion bags; use only glass or polypropylene containers. Ensure polypropylene containers are PVC-free and DEHP-free.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Each single dose must be given as a slow IV infusion over at least 2 hours. Administration over fewer than 2 hours can lead to pain and burning at the injection site. The rate of administration should not exceed 1.66 mg/M^2/min. Reduce rate for pain or burning at injection site, flushing of the skin, or suffusion of the conjunctiva.

ACTIONS

An alkylating agent of the nitrosourea group with antitumor activity, cell-cycle phase nonspecific. Exact mechanism of action is unknown. Alkylates DNA and RNA and may inhibit several key enzymatic processes. Metabolites may contribute to antineoplastic and toxic activities. Effectively crosses the blood-brain barrier. Elimination half-life ranges from 15 to 75 minutes. Excreted in changed form in urine. Small amounts excreted as respiratory CO_2.

INDICATIONS AND USES

Palliative therapy as a single agent or in established combination therapies in the treatment of brain tumors, multiple myeloma, Hodgkin lymphoma, and some non-Hodgkin lymphomas.

CONTRAINDICATIONS

Hypersensitivity to carmustine or its components.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Delayed bone marrow suppression, notably thrombocytopenia and leukopenia, is a dose-limiting, common, and severe toxic effect of carmustine. May contribute to bleeding and overwhelming infection. ■ Pulmonary toxicity is dose related. Risk is increased with a cumulative dose greater than 1,400 mg/M^2. Other risk factors include a past history of lung disease and duration of treatment. Toxicity is characterized by pulmonary infiltrates and/or fibrosis. Delayed-onset pulmonary toxicity has occurred years after treatment and can result in death, particularly in patients who received it in childhood or early adolescence. ■ Secondary malignancies, including acute leukemia and bone marrow dysplasias, have been reported in patients treated with alkylating agents.

Monitor:

Determine absolute patency and quality of vein and adequate circulation of extremity. Severe cellulitis may result from extravasation. ■ Obtain baseline CBC, including leukocyte and platelet counts. Monitor weekly for at least 6 weeks after each dose. Wait at least 6 weeks between doses. Thrombocytopenia occurs at about 4 weeks postadministration, and leukopenia occurs at about 5 to 6 weeks. Each persists for 1 to 2 weeks. ■ Obtain baseline pulmonary function studies and monitor pulmonary function frequently during treatment. Risk of pulmonary toxicity is increased in patients with a baseline below 70% of the predicted forced vital capacity (FVC) or carbon monoxide diffusing capacity (DLco). ■ Obtain baseline and periodic SCr. Monitor patients with compromised renal function closely for toxicity; see Dose Adjustments. ■ Periodic monitoring of liver function tests is recommended. ■ Nausea and vomiting can be severe. Prophylactic administration of antiemetics recommended. ■ Avoid contact of carmustine solution with the skin. Immediately wash the skin or mucosa with soap and water if contact occurs. ■ Observe for any signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Maintain hydration. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Long-term monitoring for the development of secondary malignancies is recommended.

Patient Education:

Avoid pregnancy. Females of reproductive potential should use highly effective contraception during treatment and for at least 6 months after completion of therapy. Males of reproductive potential should use effective contraception during treatment and for at least 3 months after completion of therapy. ■ Male fertility may be compromised. ■ Promptly report stinging or burning at IV site. ■ Weekly laboratory monitoring required. ■ Promptly report shortness of breath, cough, or other S/S of pulmonary toxicity. ■ Seek medical attention in the event of a seizure. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Can cause fetal harm based on mechanism of action and findings in animals. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. Risk versus benefit must be carefully considered due to a high risk of pulmonary toxicity occurring years after treatment and resulting in death.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ Toxicity may be increased. ■ Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Potentiated by **cimetidine**; increased myelosuppression (e.g., leukopenia and neutropenia) have been reported with concurrent use. ■ Phenobarbital induces the metabolism of carmustine and may compromise its antitumor activity. ■ Inhibits **digoxin and phenytoin**; may reduce serum levels. ■ Do not administer **vaccines** to patients receiving antineoplastic drugs. ■ See Dose Adjustments.

SIDE EFFECTS

The most common adverse reactions are myelosuppression, nausea, pneumonitis, pulmonary toxicity, renal toxicity, and vomiting. Many reactions are dose related and can be reversed. Bone marrow toxicity (especially leukopenia and thrombocytopenia) is most pronounced at 4 to 6 weeks; can be severe and cumulative with repeated dosage. Other reported reactions include acute leukemia and bone marrow dysplasias (following long-term therapy), anemia, anorexia, blurred vision, chest pain, conjunctival edema and hemorrhage, diarrhea, elevated liver function test, encephalopathy, flushing of skin and suffusion of conjunctiva from too-rapid infusion rate, gynecomastia, headache, hyperpigmentation and burning of skin (from actual contact with solution), hypersensitivity reactions, hypotension, loss of depth perception, nausea and vomiting, neuroretinitis, opportunistic infections, pulmonary infiltrates or fibrosis, renal abnormalities, seizures, tachycardia, and veno-occlusive disease.

ANTIDOTE

Notify physician of all side effects. Most will decrease in severity with reduced dosage, increased time span between doses, or symptomatic treatment. May reduce therapeutic effectiveness. Bone marrow suppression may require withholding carmustine until recovery occurs. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) may be required. Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity.

CASIMERSEN

(**KAS**-i-**MER**-sen)
Amondys 45
Antisense oligonucleotide
pH 7.5

USUAL DOSE

30 mg/kg once a week.

PEDIATRIC DOSE

30 mg/kg/dose once a week.

DOSE ADJUSTMENTS

Renal:

No dosage adjustments provided by manufacturer.

Hepatic:

No dosage adjustments provided by manufacturer.

DILUTION

Allow vials to reach room temperature before dilution. Inspect for particulate matter before and after dilution; do not use if small particles are observed. Mix contents of each vial by inverting 2 or 3 times; ***do not shake***. Use a 21-gauge or smaller needle to withdraw calculated volume, and dilute with NS to a total volume of 100 to 150 mL. Gently invert 2 or 3 times to mix.

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than NS.

RATE OF ADMINISTRATION

Administer as an IV infusion over 35 to 60 minutes immediately after dilution. Use a 0.2-micron filter attached to primary IV tubing. Complete infusion within 4 hours.

ACTIONS

Casimersen binds exon 45 of dystrophin premessenger RNA. This results in exclusion of this exon during mRNA procession, which allows for production of internally truncated dystrophin protein in patients with genetic mutations that are amenable to exon 45 skipping.

INDICATIONS AND USES

Duchenne muscular dystrophy (DMD) in patients who have a confirmed mutation of the DMD gene that is amenable to exon 45 skipping.

CONTRAINDICATIONS

None listed.

PRECAUTIONS

Kidney toxicity:

Nephrotoxicity, including potentially fatal glomerulonephritis, has been reported; monitor kidney function. Serum creatinine may not be a reliable measure of renal function in patients with DMD; refer to a nephrologist.

Monitor:

Monitor for signs/symptoms of renal disfunction. Monitor proteinuria by dipstick urinalysis (baseline and monthly), and monitor serum cystatin C and urine protein-to-creatinine ratio (baseline and every 3 months). Monitor for hypersensitivity reactions during infusion.

Patient Education:

Notify physician of signs of cold; cough; fever; dizziness; headache; joint pain; mouth, ear, or throat pain; stomach upset; or signs of allergic reaction (hives; rash; chest tightness; trouble breathing or swallowing; swelling of mouth, face, lips, tongue, or throat; unusual hoarseness).

Maternal/Child:

DMD usually affects males, so no pregnancy information is available. The risk vs benefit of breast-feeding should be considered.

Elderly:

No specific problems documented.

DRUG/LAB INTERACTIONS

No known significant interactions.

SIDE EFFECTS

Nausea, dizziness, headache, arthralgia, otalgia, otitis media, cough, oropharyngeal pain, upper respiratory infection, fever.

ANTIDOTE

Discontinue infusion and treat appropriately for severe hypersensitivity reactions or severe renal toxicity.

CASPOFUNGIN ACETATE

(**kas**-po-**FUN**-jin **AS**-ah-tayt)
Cancidas
Antifungal
(echinocandin)
pH 6.6

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Empirical therapy:

70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of empiric therapy is based on clinical response and should continue at least until resolution of neutropenia. Patients found to have a fungal infection should be treated for a minimum of 14 days after the last positive culture; treatment should continue for at least 7 days after both neutropenia and clinical symptoms have resolved.

Candidemia and other *Candida* infections:

70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of treatment is based on clinical and microbiologic response. Usually continued for at least 14 days after the last positive culture. Persistently neutropenic patients may require a longer course of therapy pending resolution of the neutropenia.

Esophageal candidiasis:

50 mg daily as an infusion. Continue for 7 to 14 days after symptom resolution. A 70-mg loading dose has not been studied for this indication. Suppressive oral therapy following treatment with caspofungin may be considered to decrease the risk of relapse of oropharyngeal candidiasis in patients with HIV infections.

Invasive aspergillosis:

70 mg as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/day. Duration of treatment is based on severity of the underlying disease, recovery from immunosuppression, and clinical response.

PEDIATRIC DOSE

Pediatric patients 3 months to 17 years of age (for all indications):

70 mg/M^2 as an infusion on Day 1. Beginning on Day 2, reduce subsequent doses to 50 mg/M^2/day. Regardless of the patient's calculated dose, the loading dose and/or the daily maintenance dose should not exceed a maximum of 70 mg. Duration of therapy for each indication should be individualized as outlined in Usual Dose.

DOSE ADJUSTMENTS

All diagnoses:

Adult and pediatric patients:

Dose adjustment is not indicated based on age, gender, or race. ■ See Drug/Lab Interactions.

Adults:

Dose adjustment is not indicated in patients with impaired renal function or in patients with mild impaired hepatic function (Child-Pugh score 5 to 6). ■ In patients with moderate hepatic insufficiency (Child-Pugh score 7 to 9), reduce daily doses to 35 mg with a 70-mg loading dose administered on Day 1 where appropriate. ■ Dose may be increased from 50 to 70 mg daily in empirically treated febrile neutropenic patients who are not clinically responding to the 50-mg dose; experience is limited. ■ In patients receiving concurrent administration of rifampin, increase the daily dose to 70 mg. An increase in the daily dose to 70 mg/day should be considered in patients who are not clinically responding and are taking other inducers and/or mixed inducers/inhibitors of caspofungin clearance, specifically carbamazepine, dexamethasone, efavirenz, nevirapine, and phenytoin.

Pediatric patients:

If the 50-mg/M^2 daily dose is well tolerated but does not provide adequate clinical response, it may be increased to 70 mg/M^2 (not to exceed a total dose of 70 mg). ■ There is no experience in pediatric patients with any degree of hepatic insufficiency. ■ In pediatric patients receiving concurrent administration of rifampin (Rifadin), increase the daily dose to 70 mg/M^2 (not to exceed an actual daily dose of 70 mg). Consider a daily dose of 70 mg/M^2 (not to exceed a total dose of 70 mg) in pediatric patients receiving other inducers of caspofungin clearance, specifically carbamazepine, dexamethasone, efavirenz, nevirapine, and phenytoin.

DILUTION

Available in 70-mg and 50-mg single-dose vials. Select appropriate vial size. If refrigerated product is used, allow vial to come to room temperature. Reconstitute selected dose with 10.8 mL of NS, SWFI, or BWFI. Mix gently to achieve a clear solution; should dissolve completely. The 70-mg vial will yield 7 mg/mL, and the 50-mg vial will yield 5 mg/mL.

Adults:

Based on the concentrations noted above, withdraw the appropriate volume required to provide the correct dose and add to an IV bag or bottle containing 250 mL of NS, ½NS, ¼NS, or LR for infusion. In fluid-restricted or pediatric patients, the appropriate volume of caspofungin may be added to reduced volumes of the above solutions, not to exceed a final concentration of 0.5 mg/mL.

Pediatric patients:

The choice of vial used should be based on the total dose to be administered. Pediatric doses less than 50 mg should be withdrawn from a 50-mg vial, if available, to ensure accuracy. After reconstitution, withdraw the volume required to provide the correct dose, and add to a volume of NS, ½NS, ¼NS, or LR for infusion to achieve a final concentration not to exceed 0.5 mg/mL.

Storage:

Cancidas: Refrigerate unopened vials. ***Generic:*** Store at CRT.

Reconstituted vials of either product may be stored at or below 25° C (77° F) for 1 hour before preparing as an infusion solution. Discard any unused reconstituted solution. Fully diluted solutions may be stored at or below 25° C (77° F) for 24 hours or refrigerated for 48 hours.

COMPATIBILITY

Manufacturer states, “Do not mix or co-infuse caspofungin with other medications. Do not use diluents containing dextrose.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion evenly distributed over 1 hour. **Do not** administer by IV bolus administration.

ACTIONS

An echinocandin antifungal. A glucan synthesis inhibitor. It inhibits the synthesis of beta (1,3)-D-glucan, an essential component of the cell wall of susceptible *Aspergillus* and *Candida* species. Beta (1,3)-D-glucan is not found in human cells. Extensively bound to albumin (97%). After completion of an IV infusion, plasma concentrations decline in several phases, each with its own half-life (e.g., β-phase: 9 to 11 hours; γ-phase: 40 to 50 hours). Distribution, rather than excretion or biotransformation, is the primary mechanism influencing plasma clearance. Slowly metabolized by hydrolysis and *N*-acetylation. Excreted in urine and feces.

INDICATIONS AND USES

The following indications apply to adult and pediatric patients 3 months of age and older.

Empirical therapy for presumed fungal infections in febrile, neutropenic patients. ■ Treatment of invasive aspergillosis in patients who are refractory to or intolerant of other therapies (i.e., amphotericin B and/or itraconazole). ***Limitation of use:*** Has not been studied for initial therapy for invasive aspergillosis. ■ Treatment of esophageal candidiasis. ***Limitation of use:*** Has not been approved for the treatment of oropharyngeal candidiasis. ■ Treatment of candidemia and the following *Candida* infections: intra-abdominal abscesses, peritonitis, and pleural space infections. ***Limitation of use:*** Has not been studied in endocarditis, osteomyelitis, and meningitis due to *Candida*.

CONTRAINDICATIONS

Known hypersensitivity to caspofungin or any of its components.

PRECAUTIONS

Concomitant use with cyclosporine is not recommended unless the potential benefit outweighs the risk; see Monitor and Drug/Lab Interactions. ■ Abnormal LFTs have been seen in healthy volunteers and in adult and pediatric patients treated with caspofungin. In some patients with serious underlying conditions who were receiving multiple concomitant medications with caspofungin, isolated cases of clinically significant hepatic dysfunction, hepatitis, and hepatic failure have been reported. A causal relationship to caspofungin has not been established. ■ There is no clinical experience in adult patients with severe hepatic insufficiency (Child-Pugh score greater than 9) or in pediatric patients with any degree of hepatic impairment. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ Histamine-mediated reactions, including angioedema, bronchospasm, facial swelling, pruritus, rash, and sensation of warmth, have also been reported. ■ Cases of Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN), some with a fatal outcome, have been reported. Use caution in patients with a history of allergic skin reactions. ■ Clinical failures due to drug resistance in patients receiving caspofungin therapy have been reported.

Monitor:

Most patients have serious underlying medical conditions (e.g., bone marrow transplant, HIV, malignancies) requiring multiple concomitant medications. Obtain baseline studies as required and repeat as indicated. ■ Monitor vital signs. ■ Observe for S/S of a hypersensitivity/histamine-mediated reaction (e.g., angioedema, bronchospasm, facial swelling, pruritus, rash, sensation of warmth). ■ Monitor liver function tests (e.g., AST, ALT). Evaluate risk versus benefit of continuing therapy in patients with evidence of worsening hepatic function. ■ Monitor liver function in patients receiving therapy with both caspofungin and cyclosporine. Risk/benefit of continued concomitant therapy should be evaluated in patients who develop abnormal liver function tests. ■ See Drug/Lab Interactions.

Patient Education:

Review all medical conditions and medications before beginning treatment. ■ Promptly report pain at infusion site, symptoms of hypersensitivity reactions (e.g., angioedema, bronchospasm, facial swelling, pruritus, rash, sensation of warmth), or hepatic toxicity (e.g., jaundice). ■ Advise of the potential risk to a fetus. Inform health care provider if pregnant, become pregnant, or are thinking about becoming pregnant. ■ Inform health care provider if plan to breast-feed infant.

Maternal/Child:

Based on animal studies, may cause fetal harm. ■ There are no data on the presence of caspofungin in human milk, the effects on the breast-fed child, or the effects on milk production. Has been found in the milk of lactating, drug-treated rats. ■ Safety and effectiveness for use in neonates and infants under 3 months of age has not been established.

Elderly:

Response similar to that in younger patients. Dose adjustment is not required; however, greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Concomitant use with **cyclosporine** is not recommended unless benefit outweighs risk. An increase in the AUC of caspofungin and increases in liver function tests have been reported. ■ Pharmacokinetics of caspofungin are not altered by **amphotericin B, itraconazole, mycophenolate, nelfinavir, or tacrolimus**. ■ Serum concentrations of tacrolimus may be somewhat decreased with concomitant administration; monitor tacrolimus concentrations and adjust dose as indicated. ■ **Inducers of caspofungin clearance** (e.g., carbamazepine, dexamethasone, efavirenz, nevirapine, phenytoin, rifampin) may significantly increase caspofungin clearance and necessitate an increase in caspofungin dose; see Dose Adjustments.

SIDE EFFECTS

Side effect profile is similar in both adult and pediatric patients. Incidence difficult to assess because of multiple medical conditions and multiple medications. The most commonly reported side effects include chills, diarrhea, elevated liver function tests (e.g., alkaline phosphatase, ALT, AST), fever, hypokalemia, hypotension, and rash. Other side effects reported include abdominal pain; anemia; ARDS; central line infection; cough; decreased hematocrit, hemoglobin, and WBC; diaphoresis; dyspnea; erythema; flushing; headache; hyperbilirubinemia; hypercalcemia; hyperglycemia; hyperkalemia; hypertension; hypomagnesemia; increased BUN/SCr; increased RBCs and protein in urine; infusion-related reactions; injection site reactions; mucosal inflammation; nausea; peripheral edema; phlebitis; pneumonia; pulmonary edema; radiographic infiltrates; respiratory failure; tachycardia; tachypnea; and vomiting. Possible histamine-mediated/hypersensitivity reactions (e.g., angioedema, bronchospasm, facial swelling, pruritus, rash, sensation of warmth) and anaphylaxis have been reported.

Post-Marketing:

Erythema multiforme, hepatic necrosis, hepatobiliary adverse reactions (e.g., clinically significant hepatic dysfunction, hepatitis, hepatic failure) in adult and pediatric patients with serious underlying medical conditions, increased gamma-glutamyl transferase, pancreatitis, peripheral edema, renal dysfunction (clinically significant), skin exfoliation, Stevens-Johnson syndrome, swelling, and toxic epidermal necrolysis.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Discontinue caspofungin and notify physician of abnormal liver function tests progressing to clinical S/S of liver disease. Rash may be the first sign of an exfoliative skin disorder in immunocompromised patients; discontinue caspofungin and notify physician. Histamine-mediated reactions may require discontinuation of caspofungin and/or appropriate treatment. Discontinue caspofungin at the first S/S of a serious hypersensitivity reaction. Treat anaphylaxis as indicated. Resuscitate as necessary. Not removed by hemodialysis.

CEFAZOLIN SODIUM

(sef-**AYZ**-oh-lin **SO**-dee-um)
Ancef, Kefzol
Antibacterial (cephalosporin)
pH 4.5 to 7

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Cefazolin:

250 mg to 2 Gm every 8 hours. Up to 6 Gm is usual, but 12 Gm in 24 hours has been used, depending on severity of infection.

Mild infections:

250 to 500 mg every 8 hours.

Moderate to severe infections:

500 mg to 1 Gm every 8 hours.

Life-threatening infections (e.g., endocarditis, septicemia):

2 Gm every 8 hours.

Pneumococcal pneumonia:

500 mg every 12 hours.

Acute, uncomplicated urinary tract infections:

1 Gm every 12 hours.

Perioperative prophylaxis:

1 to 2 Gm 30 minutes to 1 hour before incision. For lengthy procedures (e.g., 2 hours or more), 0.5 to 1 Gm may be repeated in the OR. Administer every 6 to 8 hours for 24 hours postoperatively.

Endocarditis prophylaxis (unlabeled):

1 Gm 30 minutes before surgery.

PEDIATRIC DOSE

Mild to moderate infections:

25 to 100 mg/kg/day, divided every 8 hours. Maximum daily dose is 6 gm/day.

Severe infections:

100-150 mg/kg/day divided every 6-8 hours; maximum daily dose 12 gm/day.

Perioperative prophylaxis:

The manufacturer does not provide dosage recommendations in pediatric patients. However, one source recommends 30 mg/kg (not to exceed 2 Gm) administered within 60 minutes of the surgical incision.

Endocarditis prophylaxis (unlabeled):

50 mg/kg 30 minutes before the start of surgery. Do not exceed 1 Gm.

NEONATAL DOSE

See Maternal/Child. American Academy of Pediatrics (AAP) recommends:

7 days of age or younger regardless of weight:

25 mg/kg every 12 hours.

8 to 28 days of age; weight 2 kg or less:

25 mg/kg every 12 hours.

8 to 28 days of age; weight more than 2 kg:

25 mg/kg every 8 hours.

DOSE ADJUSTMENTS

Reduced doses or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. In impaired renal function, the initial dose in adults and pediatric patients should be as above. Reduce all subsequent doses according to the following charts.

Cefazolin Dose Guidelines in Impaired Renal Function for Adults

CrCl	Dose	Frequency
CrCl >55 mL/min	Full	Normal
CrCl 35–54 mL/min	Full	q 8 hr or less frequently
CrCl 11–34 mL/min	½ Usual dose	q 12 hr
CrCl 10 mL/min	½ Usual dose	q 18–24 hr

Cefazolin Dose Guidelines in Impaired Renal Function for Pediatric Patients

Creatinine Clearance (mL/min)	Dose	Frequency
>70 mL/min	Full	Normal
40–70 mL/min	60% of normal daily dose[a]	q 12 hr
20–40 mL/min	25% of normal daily dose[a]	q 12 hr
5–20 mL/min	10% of normal daily dose[a]	q 24 hr

[a] In equally divided doses.

DILUTION

Each 1 Gm or fraction thereof of the lyophilized powder must be reconstituted with at least 2.5 mL of SWFI. Shake well. To reduce the incidence of thrombophlebitis, may be further diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solutions (see chart on inside back cover or literature) and given as an intermittent infusion. Available in several forms (other than vials of lyophilized powder), including dual-chamber DUPLEX containers with dextrose, premixed with dextrose in a frozen Galaxy container, Add-Vantage vials, and pharmacy bulk vials. Refer to manufacturer's prescribing information for specific preparation and storage requirements.

Storage:

Before reconstitution of the lyophilized powder, protect from light and store at CRT. Give within 24 hours of preparation if stored at CRT or within 10 days if under refrigeration. Discard pharmacy bulk vials within 4 hours after initial entry.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer separately and flush IV line before and after administration.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Over 3 to 5 minutes.

Intermittent infusion:

Extend administration time as indicated by amount of solution and condition of patient. Usually administered over 30 to 60 minutes.

ACTIONS

A semi-synthetic, first-generation cephalosporin antibiotic that is bactericidal through inhibition of cell wall synthesis to some gram-positive and gram-negative organisms, including staphylococci and streptococci. Peak serum levels achieved by end of infusion. Widely distributed in most tissues and body fluids (CSF minimal), including bone, gallbladder, myocardium, and skin and soft tissue. Serum half-life is 1.8 hours. Excreted rapidly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections of the bone, joints, skin, soft tissue, respiratory tract, biliary tract, and GU tract; septicemia; and endocarditis. Effective only if the causative organism is susceptible. ■ Perioperative prophylaxis.

Unlabeled uses:

Prophylaxis of bacterial endocarditis.

CONTRAINDICATIONS

Previous immediate hypersensitivity reaction (e.g., anaphylaxis, serious skin reactions) to cefazolin or the cephalosporin class of antibiotics, penicillins, or other beta-lactams; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Hypersensitivity reactions have been reported with administration of corn-derived, dextrose-containing products to patients with or without a history of hypersensitivity to corn products. Cefazolin in the DUPLEX and Galaxy containers contains dextrose. ■ Sensitivity studies indicated to determine susceptibility of the causative organisms to cefazolin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefazolin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue antibiotic therapy for at least 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ With inappropriately high doses, seizures may occur in patients with impaired renal function. ■ May be associated with an elevated INR, especially in patients with impaired renal or hepatic function, those with a poor nutritional state, and those receiving extended courses of antimicrobial therapy. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefazolin.

Monitor:

Obtain baseline PT/INR and monitor, especially in at-risk patients (see Precautions); vitamin K may be indicated. ■ Watch for early symptoms of hypersensitivity reactions. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT/INR).

Patient Education:

Report promptly any bleeding or bruising, diarrhea, or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Safety for use in premature infants and neonates under 1 month of age not established; immature renal function will increase blood levels. See Pediatric Dose.

Elderly:

No specific problems documented. ■ See Usual Dose and Dose Adjustments.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics). ■ **Probenecid** inhibits excretion, resulting in elevated cefazolin levels. Dose reduction of cefazolin may be necessary. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ May result in false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ Positive direct Coombs' tests have been reported. ■ See Compatibility and Side Effects.

SIDE EFFECTS

Anorexia; CDAD; diarrhea; elevated BUN and creatinine levels; elevated PT/INR; hypersensitivity reactions, including anaphylaxis; leukopenia; local site pain; nausea and vomiting; neutropenia; oral thrush; phlebitis; positive direct and indirect Coombs' test; pruritis; transient elevation of AST, ALT, and alkaline phosphatase; seizures (large doses); thrombophlebitis; vaginal itching or discharge. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Hepatitis and renal failure have been reported. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic impairment (including cholestasis), pancytopenia, renal impairment, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of cefazolin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Discontinue cefazolin and treat hypersensitivity reaction as indicated (airway, oxygen, IV fluids, antihistamines [e.g., diphenhydramine], corticosteroids [e.g., hydrocortisone sodium succinate], epinephrine, pressor amines [e.g., dopamine]) and resuscitate as necessary. Hemodialysis may be useful in overdose.

CEFEPIME HYDROCHLORIDE

(**SEF**-eh-pim hy-droh-**KLOR**-eyed)
Maxipime
Antibacterial (cephalosporin)
pH 4 to 6

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Adults:

Range is from 1-2 Gm every 8-12 hours. Dose and frequency based on severity of disease and/or specific susceptibility of the causative organism according.

PEDIATRIC DOSE

Pediatric patients 2 months to 16 years; weight up to 40 kg:

50 mg/kg every 12 hours with the duration of therapy as outlined under Usual Dose.

Increase frequency to every 8 hours for empiric monotherapy in febrile neutropenia and for treatment of pneumonia due to *Pseudomonas aeruginosa*. Do not exceed adult dose.

DOSE ADJUSTMENTS

In impaired renal function, the initial dose should be as stated earlier (except in patients undergoing hemodialysis). All remaining doses should be reduced based on CrCl according to the following chart (e.g., if the normal dose is 1 Gm every 12 hours with a CrCl greater than 60, the maintenance dose would be reduced to 1 Gm every 24 hours with a CrCl between 30 and 60 mL/min). Dose reductions should be comparable in ***pediatric patients.***

Cefepime Dose Guidelines in Impaired Renal Function

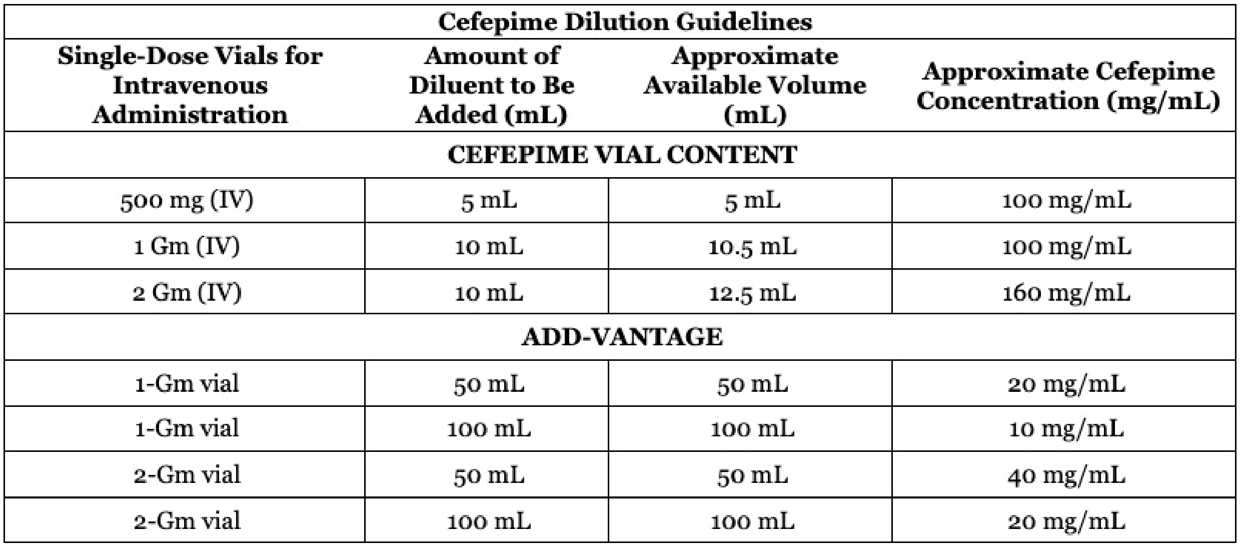
Creatinine Clearance (mL/min)	**Recommended Maintenance Schedule (relative to normal dosing schedule)**			
Normal Recommended Dosing Schedule (>60 mL/min)	**500 mg q 12 hr**	**1 Gm q 12 hr**	**2 Gm q 12 hr**	**2 Gm q 8 hr**
30-60 mL/min	500 mg q 24 hr	1 Gm q 24 hr	2 Gm q 24 hr	2 Gm q 12 hr
11-29 mL/min	500 mg q 24 hr	500 mg q 24 hr	1 Gm q 24 hr	2 Gm q 24 hr
<11 mL/min	250 mg q 24 hr	250 mg q 24 hr	500 mg q 24 hr	1 Gm q 24 hr
CAPD	500 mg q 48 hr	1 Gm q 48 hr	2 Gm q 48 hr	2 Gm q 48 hr
Hemodialysis[a]	1 Gm on Day 1, then 500 mg q 24 hr.			1 Gm q 24 hr

[a] On hemodialysis days, cefepime should be administered following hemodialysis. Whenever possible, administer at the same time each day.

Consult literature or Important IV Therapy Facts, p. xix, for conversion formula if dose is to be based on SCr. ■ Reduced dose may be required in the elderly based on renal function. ■ Dose adjustment not required in impaired hepatic function.

DILUTION

Vials of the lyophilized powder for IM/IV use may be reconstituted with D5W, NS, SWFI, (see the following chart) and then further diluted with NS, D5W, D10W, D5NS, D5LR. Concentrations between 1 mg/mL and 40 mg/mL are acceptable. (500 mg reconstituted with 5 mL = 100 mg/mL, further diluted with 95 mL = 5 mg/mL, with 45 mL = 10 mg/mL.) Available in several forms (other than vials of lyophilized powder), including Add-Vantage vials, dual-chamber DUPLEX containers with dextrose, and premixed with dextrose in a frozen Galaxy container. Refer to manufacturer’s prescribing information for specific preparation and storage requirements.



Cefepime Dilution Guidelines

Single-Dose Vials for Intravenous Administration	Amount of Diluent to Be Added (mL)	Approximate Available Volume (mL)	Approximate Cefepime Concentration (mg/mL)
CEFEPIME VIAL CONTENT			
500 mg (IV)	5 mL	5 mL	100 mg/mL
1 Gm (IV)	10 mL	10.5 mL	100 mg/mL
2 Gm (IV)	10 mL	12.5 mL	160 mg/mL
ADD-VANTAGE			
1-Gm vial	50 mL	50 mL	20 mg/mL
1-Gm vial	100 mL	100 mL	10 mg/mL
2-Gm vial	50 mL	50 mL	40 mg/mL
2-Gm vial	100 mL	100 mL	20 mg/mL

Filters:

Specific information from studies not available; contact manufacturer for further information.

Storage:

See manufacturer's directions. Recommendations for storing vary from CRT (20° to 25° C [68° to 77° F]) to 2° to 25° C (36° to 77° F) in the dry state; protect from light. Most reconstituted or diluted solutions are stable for 24 hours at CRT and 7 days if refrigerated (recommendations may vary with diluent). As with other cephalosporins, the color of cefepime tends to darken depending on storage conditions; however, the product potency is not adversely affected when stored as recommended.

COMPATIBILITY

Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion. May be used concomitantly with aminoglycosides (e.g., gentamicin, tobramycin), aminophylline, metronidazole, and vancomycin, but these drugs must never be mixed in the same infusion (mutual inactivation or other potential interactions). If concurrent therapy with cefepime is indicated, each of these antibiotics can be administered separately. Flush IV line before and after administration.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not use plastic containers in a series connection; could result in air embolism. May be given (off label) as extended infusion: IV 2 gm infused over 3–4 hours or Continuous infusion: 4–6 gm infused over 24 hours. May give a first does of 2 gm over 30 minutes followed by infusion.

Intermittent infusion:

A single dose equally distributed over 30 minutes.

ACTIONS

A semi-synthetic, broad-spectrum, fourth-generation cephalosporin antibiotic. Bactericidal to a wide range of both gram-positive and gram-negative organisms. Cefepime is highly resistant to hydrolysis by most beta-lactamases and exhibits rapid penetration into gram-negative bacterial cells. Acts by inhibition of bacterial wall synthesis. Peak serum levels achieved by end of infusion; half-life is 1.7 to 2.3 hours. Well distributed into many body fluids and tissues. Partially metabolized; 85% excreted unchanged in urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of moderate to severe pneumonia caused by susceptible organisms, including cases associated with concurrent bacteremia. ■ Treatment of uncomplicated and complicated urinary tract infections caused by susceptible organisms, including pyelonephritis and cases associated with concurrent bacteremia. ■ Treatment of uncomplicated skin and skin structure infections caused by susceptible organisms. ■ Empiric monotherapy in the treatment of febrile neutropenic patients; see Precautions. ■ Treatment of complicated intra-abdominal infections in adults; used in combination with metronidazole (Flagyl). ■ See literature for list of susceptible organisms.

CONTRAINDICATIONS

Patients who have shown immediate hypersensitivity reactions to cefepime, any cephalosporin, penicillin, or other beta-lactam antibiotic; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including anaphylaxis, have been reported. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Cross-sensitivity among beta-lactam antibacterial agents has been documented; however, the actual incidence of cross-allergenicity is not established. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to cefepime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefepime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ IM injection is used only for mild to moderate urinary tract infections due to *E. coli*. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ May decrease prothrombin activity, especially in patients with impaired renal or hepatic function, those in a poor nutritional state, and those receiving extended courses of antimicrobial therapy. ■ Serious neurologic adverse events, including aphasia, encephalopathy (changes in consciousness, including coma, confusion, hallucinations, and stupor), myoclonus, nonconvulsive status epilepticus, and seizures, have occurred; life-threatening or fatal events have been reported. Patients with impaired renal function may be at greater risk, especially if doses are not properly adjusted; see Dose Adjustments and monitor closely. In most cases, neurotoxicity was reversible and resolved after cefepime was discontinued and/or after hemodialysis. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefepime. ■ Higher-end doses may increase incidence and severity of rash and require cefepime to be discontinued. ■ Insufficient data exist for monotherapy of febrile neutropenia in patients at high risk for severe infection (e.g., history of recent bone marrow transplant, hypotension on presentation, underlying hematologic malignancy, severe or prolonged neutropenia). ■ Positive direct Coombs' tests have been reported during treatment with cefepime. Discontinue drug and institute appropriate therapy in patients who develop hemolytic anemia.

Monitor:

Obtain baseline CBC with differential and platelets and SCr. ■ Obtain baseline PT and monitor, especially in at-risk patients (see Precautions); vitamin K may be indicated. ■ Watch for early symptoms of a hypersensitivity reaction. ■ Monitor for neurotoxicity (e.g., aphasia, encephalopathy, myoclonus, nonconvulsive status epilepticus, seizures). ■ May cause thrombophlebitis. ■ Monitor and re-evaluate frequently the need for continued antimicrobial treatment in patients whose fever resolves but who remain neutropenic for more than 7 days. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report neurologic S/S (e.g., aphasia, change in consciousness, confusion, hallucinations, seizures, stupor).

Maternal/Child:

Category B: safety for use during pregnancy, labor and delivery, and breast-feeding not established; use only if clearly needed. ■ Safety and effectiveness have not been established for use in infants under 2 months of age, in pediatric patients for treatment of complicated intra-abdominal infections, or for treatment of serious infections in pediatric patients in whom the suspected or proven pathogen is *Haemophilus influenzae* type b. ■ An alternate agent with demonstrated clinical effectiveness should be used in pediatric patients in whom meningitis or meningeal seeding from a distant infection site is suspected or documented. ■ Pharmacokinetics in pediatric patients and adults is similar. Dose modification similar to adults is indicated in impaired renal function; see Dose Adjustments. ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins. ■ Positive Coombs' test may be observed in newborns whose mothers have received cephalosporin antibiotics before parturition.

Elderly:

Consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy; reduced dose or extended intervals may be indicated. Serious adverse reactions (e.g., aphasia, encephalopathy, myoclonus, nonconvulsive status epilepticus, seizures) have occurred in elderly patients with renal impairment given unadjusted doses of cefepime; see Dose Adjustments. Monitor for hypocalcemia.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics); monitor renal function closely. ■ Risk of ototoxicity may be increased when administered with aminoglycosides (e.g., gentamicin). ■ May have a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ See Compatibility and Side Effects.

SIDE EFFECTS

Decreased phosphorus, increased ALT and AST, increased PT and PTT, local reactions (including phlebitis), pain and/or inflammation, positive Coombs' test, and rash are the most common adverse reactions. At the highest doses (2 Gm every 8 hours), the most common adverse reactions are diarrhea, fever, headache, nausea, pruritis, rash, and vomiting. Other reported adverse reactions include the full scope of hypersensitivity reactions (e.g., anaphylaxis, itching, rash, shock, urticaria); bone marrow suppression (e.g., agranulocytosis, anemia, leukopenia, neutropenia, thrombocytopenia); CDAD; colitis; decreased calcium (more common in elderly); elevated alkaline phosphatase, BUN, calcium, creatinine, eosinophils, phosphorus, potassium, and total bilirubin; erythema; neurotoxicity (e.g., seizures [large doses, or standard doses in renally impaired patients]); oral moniliasis; and vaginitis. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Overdose:

Encephalopathy (disturbances of consciousness, including confusion, hallucinations, stupor, and coma), myoclonus, neuromuscular excitability, nonconvulsive status epilepticus, seizures.

Post-Marketing:

Agranulocytosis, anaphylaxis, aphasia, encephalopathy, myoclonus, seizures, nonconvulsive status epilepticus.

ANTIDOTE

Notify physician of any side effects. Discontinue cefepime and treat hypersensitivity reactions as indicated (airway, oxygen, IV fluids, epinephrine, corticosteroids, pressor amines [e.g., dopamine], antihistamines [e.g., diphenhydramine]). Resuscitate as necessary. Discontinue cefepime if neurotoxicity develops, and institute supportive measures as indicated. Mild cases of CDAD may respond to discontinuation of cefepime. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be useful in overdose.

CEFIDEROCOL

(**SEF**-i-**DER**-oh-kol)
Fetroja
Antibacterial (cephalosporin)
pH 5.2 to 5.8

USUAL DOSE

Pretreatment:

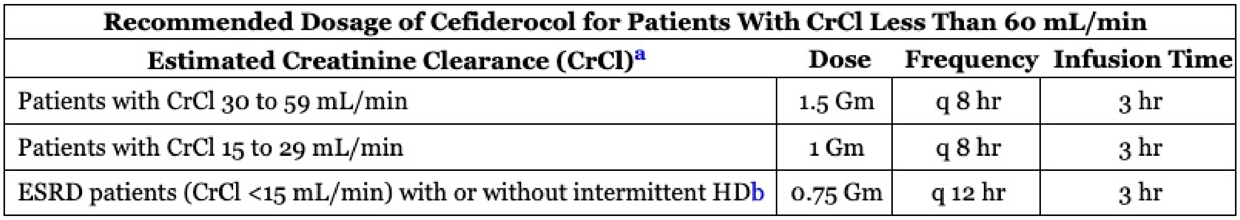
Baseline studies indicated; see Monitor.

Cefiderocol:

2 Gm every 8 hours administered as an IV infusion over 3 hours; see Dose Adjustments. Duration of therapy is 7 to 14 days. Duration guided by the severity of infection and the patient's clinical status.

DOSE ADJUSTMENTS

Adjust dose in patients with CrCl less than 60 mL/min as outlined in the following chart.



Recommended Dosage of Cefiderocol for Patients With CrCl Less Than 60 mL/min

Estimated Creatinine Clearance (CrCl)[a]	Dose	Frequency	Infusion Time
Patients with CrCl 30 to 59 mL/min	1.5 Gm	q 8 hr	3 hr
Patients with CrCl 15 to 29 mL/min	1 Gm	q 8 hr	3 hr
ESRD patients (CrCl <15 mL/min) with or without intermittent HD[b]	0.75 Gm	q 12 hr	3 hr

[a] CrCl, Creatinine clearance estimated by Cockcroft-Gault equation.

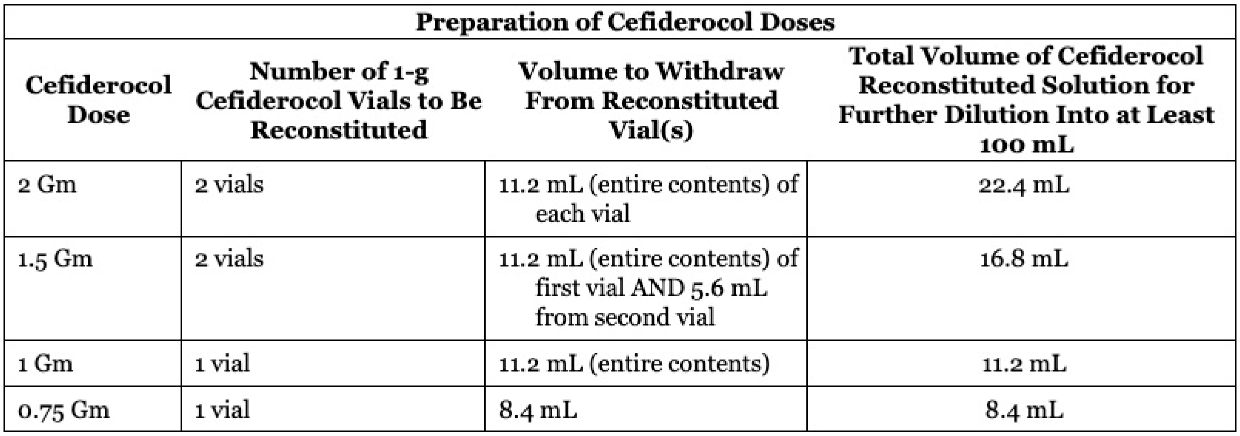
[b] Cefiderocol is removed by hemodialysis (HD); thus complete hemodialysis (HD) at the latest possible time before the start of cefiderocol dosing.

ESRD, End-stage renal disease; *HD,* hemodialysis.

■ Increase dosage to 2 Gm IV every 6 hours in patients with a CrCl 120 mL/min or greater. ■ Reduced dose or extended intervals may be indicated in elderly patients; consider age-related impaired renal function and concomitant disease states. ■ No clinically significant differences in pharmacokinetics of cefiderocol were observed based on age, sex, or race. ■ Dose reduction is not required in impaired hepatic function.

DILUTION

Available as a sterile, lyophilized powder in a 1-Gm vial. Reconstitute each 1-Gm vial with 10 mL of either NS or D5W. Shake gently to dissolve. Allow vial(s) to stand until foam dissipates (typically within 2 minutes). The final volume of reconstituted solution will be approximately 11.2 mL. To prepare the required dose, withdraw the appropriate volume of reconstituted solution from the vial as indicated in the following chart and add to an infusion bag containing 100 mL of NS or D5W. Resulting solution should be clear and colorless.



Preparation of Cefiderocol Doses

Cefiderocol Dose	Number of 1-g Cefiderocol Vials to Be Reconstituted	Volume to Withdraw From Reconstituted Vial(s)	Total Volume of Cefiderocol Reconstituted Solution for Further Dilution Into at Least 100 mL
2 Gm	2 vials	11.2 mL (entire contents) of each vial	22.4 mL
1.5 Gm	2 vials	11.2 mL (entire contents) of first vial AND 5.6 mL from second vial	16.8 mL
1 Gm	1 vial	11.2 mL (entire contents)	11.2 mL
0.75 Gm	1 vial	8.4 mL	8.4 mL

Filter:

Data not available.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. Reconstituted solution is stable for 1 hour at RT. Diluted solution in the infusion bag is stable for 4 hours at RT. Discard any unused solution in the vial.

COMPATIBILITY

Compatible with NS and D5W. The manufacturer states that, “The compatibility of cefiderocol solution for administration with solutions containing other drugs or other diluents has not been established.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 3 hours.

ACTIONS

A cephalosporin antibacterial drug with activity against gram-negative aerobic bacteria. Cefiderocol functions as a siderophore and binds to extracellular free ferric iron. In addition to passive diffusion via porin channels, cefiderocol is actively transported across the outer cell membrane of bacteria into the periplasmic space using a siderophore iron uptake mechanism. Cefiderocol exerts bactericidal action by inhibiting cell wall biosynthesis through binding to penicillin-binding proteins. Cefiderocol has no clinically relevant *in vitro* activity against most gram-positive bacteria and anaerobic bacteria. Plasma protein binding (primarily to albumin) is 40% to 60%. Minimally metabolized. Terminal elimination half-life is 2 to 3 hours. Primarily excreted by the kidneys.

INDICATIONS AND USES

Treatment of complicated urinary tract infections (cUTIs), including pyelonephritis caused by susceptible gram-negative microorganisms (*Escherichia coli, Klebsiella pneumoniae, Proteus mirabilis, Pseudomonas aeruginosa,* and *Enterobacter cloacae* complex), in patients 18 years of age or older who have limited or no alternative treatment options. Approval of this indication is based on limited clinical safety and efficacy data.

CONTRAINDICATIONS

Known history of severe hypersensitivity to cefiderocol or other beta-lactam antibacterial drugs or to any other component of cefiderocol.

PRECAUTIONS

In a multinational, randomized open-label trial in critically ill patients with carbapenem-resistant gram-negative bacterial infections, an increase in all-cause mortality was observed in patients treated with cefiderocol compared with patients treated with best available therapy (BAT). Patients with nosocomial pneumonia, bloodstream infections, sepsis, or cUTIs were included in the trial. The increase in all-cause mortality occurred in patients treated for nosocomial pneumonia, bloodstream infections, or sepsis. The safety and efficacy of cefiderocol has not been established for the treatment of nosocomial pneumonia, bloodstream infections, or sepsis. Reserve cefiderocol for use in patients who have limited or no alternative treatment options for the treatment of cUTIs. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions and serious skin reactions have been reported in patients receiving beta-lactam antibacterial drugs. These reactions are more likely to occur in patients with a history of a beta-lactam hypersensitivity and/or a history of sensitivity to multiple allergens. Hypersensitivity reactions have been reported with cefiderocol. Check history of previous hypersensitivity reactions to other cephalosporins, penicillins, or carbapenems. Cross-sensitivity among beta-lactam antibacterial drugs has been established. ■ Specific sensitivity studies indicated to determine susceptibility of causative organism to cefiderocol. ■ Cross-resistance with other classes of antibacterial drugs has not been identified; therefore isolates resistant to other antibacterial drugs may be susceptible to cefiderocol. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefiderocol should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefiderocol. ■ Cephalosporins, including cefiderocol, have been implicated in triggering seizures. Nonconvulsive status epilepticus (NCSE), encephalopathy, coma, asterixis, neuromuscular excitability, and myoclonia have been reported with cephalosporins, particularly in patients with a history of epilepsy and/or when recommended dosages of cephalosporins were exceeded due to renal impairment;

see Dose Adjustments. Anticonvulsant therapy should be continued in patients with known seizure disorders.

Monitor:

Obtain baseline and periodic CBC and SCr. ■ Monitor CrCl in all patients with fluctuating renal function and adjust dosage accordingly; see Dose Adjustments. ■ CrCl 120 mL/min or greater may be seen in seriously ill patients who are receiving IV fluid resuscitation. ■ Monitor for S/S of a hypersensitivity reaction. ■ Monitor for S/S of CNS adverse reactions. If CNS adverse reactions (including seizures) occur, patients should undergo a neurologic evaluation to determine whether cefiderocol should be discontinued. ■ Closely monitor the clinical response to therapy in patients with a cUTI.

Patient Education:

Review list of allergies and medical conditions with provider. Report promptly any symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash) or neurologic symptoms (e.g., confusion, myoclonus, seizures). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Safety for use during pregnancy and breast-feeding not established. No problems documented. Use caution. ■ Safety and efficacy for use in pediatric patients younger than 18 years of age not established.

Elderly:

No specific differences in safety or effectiveness were observed between elderly and younger patients. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Cefiderocol may result in **false-positive dipstick tests** (urine protein, ketones, or occult blood). Use alternate clinical laboratory methods of testing to confirm positive tests.

SIDE EFFECTS

The most common adverse reactions include candidiasis, constipation, cough, diarrhea, elevations in liver tests, headache, hypokalemia, infusion site reactions, nausea, rash, and vomiting. Adverse reactions leading to discontinuation of therapy include diarrhea, hypersensitivity reactions, and increased hepatic enzymes. Less commonly reported adverse reactions include abdominal pain, atrial fibrillation, bradycardia, CHF, cholecystitis, cholelithiasis, *C. difficile* infection, decreased appetite, dry mouth, dysgeusia, dyspnea, fever, fluid overload, gallbladder pain, hypersensitivity reactions, hypocalcemia, increased creatine phosphokinase, insomnia, peripheral edema, pleural effusion, prolonged INR and PT, pruritus, restlessness, seizures, stomatitis, and thrombocytosis.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of cefiderocol. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Approximately 60% of cefiderocol is removed by a 3- to 4-hour hemodialysis session.

CEFOTAXIME SODIUM

(sef-oh-**TAX**-eem **SO**-dee-um)
Claforan
Antibacterial (cephalosporin)
pH 5 to 7.5

USUAL DOSE

Range is 2 to 12 Gm/24 hr. Depends on seriousness of infection. Maximum daily dose is 12 Gm. Duration of treatment depends on the organism and infection being treated. A minimum of 10 days is recommended for infections caused by *group A beta-hemolytic streptococci* to guard against the risk of rheumatic fever or glomerulonephritis.

Uncomplicated infections:

1 Gm every 12 hours.

Moderate to severe infections:

1 to 2 Gm every 8 hours.

Serious infections and septicemia:

2 Gm every 6 to 8 hours.

Life-threatening infections:

2 Gm every 4 hours.

For moderate to life-threatening infections, higher doses are often reduced after a positive clinical response.

Disseminated gonococcal infections:

1 Gm every 8 hours; continue for 24 to 48 hours after symptoms improve. Transfer to oral cefixime to complete a minimum of 1 week of treatment.

Perioperative prophylaxis:

1 Gm 30 to 90 minutes before incision. Equal to or less than 60 minutes is recommended. May be repeated in a lengthy procedure. In ***cesarean section*** give initial dose after cord is clamped, then 1 Gm at 6 and 12 hours postoperatively.

PEDIATRIC DOSE

Maximum daily dose 12 Gm/24 hr. Differentiation between premature and normal gestational age is not necessary.

0 to 1 week of age:

50 mg/kg/dose every 12 hours.

1 to 4 weeks of age:

50 mg/kg/dose every 8 hours. One source increases the interval to every 12 hours in infants weighing less than 1,200 Gm.

1 month to 12 years, weight less than 50 kg:

50 to 180 mg/kg/24 hr equally divided into 4 to 6 doses (8.3 to 30 mg/kg/dose every 4 hours or 12.5 to 45 mg/kg/dose every 6 hours). Use higher-end doses for serious infections, including meningitis.

Weight 50 kg or more:

See Usual Dose.

DOSE ADJUSTMENTS

In impaired renal function with a CrCl less than 20 mL/min/1.73 M^2, reduce dose by one-half and maintain same dosing interval. ■ Reduced doses or extended intervals may be indicated in the elderly. Consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ See Usual Dose and Drug/Lab Interactions.

DILUTION

Each dose of the lyophilized powder (500 mg, 1 Gm, 2 Gm) must be reconstituted with 10 mL SWFI, D5W, NS, or other **compatible** infusion solution (see chart on inside back cover or literature). Do not prepare with diluents having a pH above 7.5; see Compatibility. Solution color ranges from pale yellow to light amber. May be further diluted with 50 to 100 mL of **compatible** solutions and given as an intermittent infusion or added to larger volumes and given as a continuous infusion. (1 Gm in 14 mL of SWFI is isotonic.)

Available in several forms (other than vials of lyophilized powder), including premixed with dextrose in a frozen Galaxy container, in ADD-Vantage vials for use with ADD-Vantage infusion containers, and in pharmacy bulk vials. Refer to manufacturer’s prescribing information for specific preparation and storage requirements.

Storage:

Store unopened cartons at CRT. Protect from excessive light. Stability of reconstituted solutions ranges from 12 hours at RT to 10 days refrigerated depending on concentration, diluent, and infusion container; see prescribing information.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer separately and flush the IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and states, “Do not add supplementary medications to premixed plastic IV containers.” Manufacturer also states, “Should not be prepared with solutions having a pH above 7.5, such as sodium bicarbonate.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Compatibility. Injection and intermittent infusion may be given through Y-tube or three-way stopcock of infusion set.

IV injection:

A single dose equally distributed over a minimum of 3 to 5 minutes. Rapid bolus injections (less than 60 seconds) have caused life-threatening arrhythmias.

Intermittent IV:

A single dose over 30 minutes.

Continuous infusion:

500 to 1,000 mL over 6 to 24 hours, depending on total dose and concentration.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to many gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Distributed into most body tissues and fluids, including inflamed meninges. Some metabolites formed. Half-life is approximately 1 hour. Excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, intra-abdominal, bone and joint, CNS, gynecologic infections, and bacteremia/septicemia. Most effective against specific organisms (see literature). ■ Perioperative prophylaxis.

Unlabeled uses:

Treatment of disseminated gonococcal infections and Lyme disease.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefotaxime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefotaxime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for 2 to 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefotaxime. ■ Granulocytopenia and, rarely, agranulocytosis can occur, especially during prolonged therapy; see Monitor.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Monitor CBC if duration of treatment is more than 10 days. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education:

Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins.

Elderly:

No specific problems documented; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics [e.g., furosemide], NSAIDs [e.g., ibuprofen, naproxen]). ■ **Probenecid** inhibits excretion of cefotaxime, decreasing clearance by approximately 50%. Limit administration of cefotaxime to no more than 6 Gm/day when given concurrently with probenecid. ■ May be antagonized by **bacteriostatic**

antibiotics (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ See Compatibility and Side Effects. ■ May cause a positive direct **Coombs' test.** ■ May produce a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix).

SIDE EFFECTS

Generally well tolerated. The most common side effect is a local reaction at the injection site. Less frequent reactions include a full scope of hypersensitivity reactions, including anaphylaxis; CDAD; colitis; decreased hemoglobin or decreased hematocrit; decreased platelet functions; diarrhea; dyspnea; elevation of AST, ALT, total bilirubin, alkaline phosphatase, LDH, and BUN (transient); eosinophilia; fever; leukopenia; local site pain; nausea; oral thrush; positive direct Coombs' test; prolonged PT; seizures (large doses); thrombophlebitis; transient neutropenia; vaginitis; vomiting. Generally resolve after cephalosporins are discontinued. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Post-Marketing:

Arrhythmia (with rapid injection), cutaneous reactions (e.g., isolated cases of erythema multiforme, Stevens-Johnson syndrome, toxic epidermal necrolysis), encephalopathy (e.g., impairment of consciousness, abnormal movements and seizures), hematologic reactions (e.g., agranulocytosis, hemolytic anemia, thrombocytopenia), hepatic reactions (e.g., cholestasis, elevated gamma-glutamyl transferase [GGT] and bilirubin, hepatitis, jaundice), renal reactions (e.g., interstitial nephritis and transient elevations in SCr).

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of cefotaxime. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Hemodialysis may be useful in overdose.

CEFOTETAN DISODIUM

(sef-oh-**TEE**-tan dye-**SO**-dee-um)
Antibacterial
(cephalosporin)
pH 4.5 to 6.5

USUAL DOSE

Range is 1 to 6 Gm/24 hr for 5 to 10 days. Do not exceed 6 Gm/24 hr.

Urinary tract infections:

500 mg to 2 Gm every 12 hours or 1 to 2 Gm every 12 to 24 hours.

Moderate infections:

1 or 2 Gm every 12 hours.

Moderate infections of skin and skin structure:

2 Gm every 24 hours or 1 Gm every 12 hours. Give 1 or 2 Gm every 12 hours if *Klebsiella pneumoniae* is the causative organism.

Serious infections:

2 Gm every 12 hours.

Life-threatening infections:

3 Gm every 12 hours.

Pelvic inflammatory disease:

2 Gm every 12 hours for 14 days. Transfer to oral therapy at any time it is clinically appropriate, usually 48 hours after clinical improvement.

Perioperative prophylaxis:

1 to 2 Gm IV 30 to 60 minutes before incision except during cesarean section. Given only after clamping the umbilical cord in ***cesarean section.***

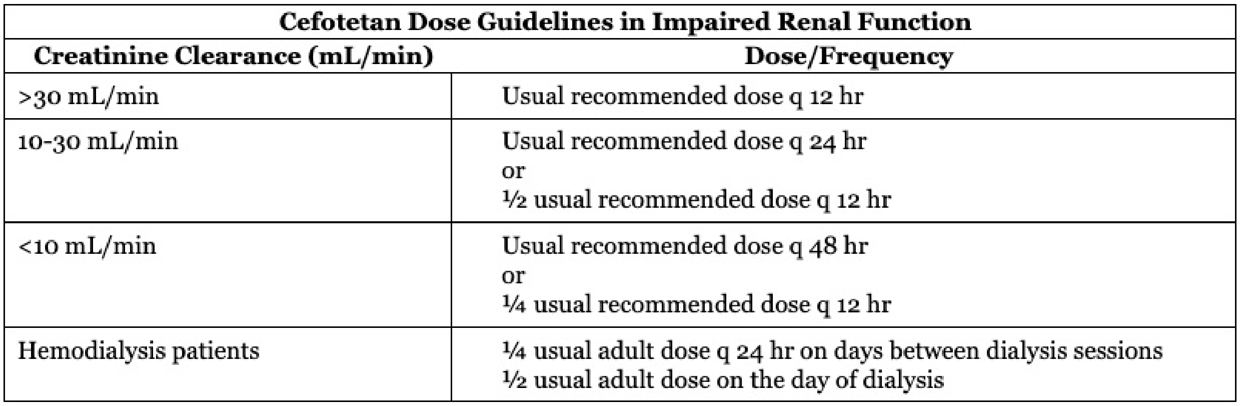
PEDIATRIC DOSE

Unlabeled:

20 to 40 mg/kg of body weight every 12 hours; see Maternal/Child.

DOSE ADJUSTMENTS

Reduced doses or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ Reduce total daily dose if renal function impaired according to the following chart.



Cefotetan Dose Guidelines in Impaired Renal Function	
Creatinine Clearance (mL/min)	**Dose/Frequency**
>30 mL/min	Usual recommended dose q 12 hr
10-30 mL/min	Usual recommended dose q 24 hr or ½ usual recommended dose q 12 hr
<10 mL/min	Usual recommended dose q 48 hr or ¼ usual recommended dose q 12 hr
Hemodialysis patients	¼ usual adult dose q 24 hr on days between dialysis sessions ½ usual adult dose on the day of dialysis

DILUTION

IV injection:

Reconstitute each 1 Gm of the lyophilized powder with 10 mL of SWFI (2 Gm with 20 mL). Shake well and let stand until clear.

Intermittent IV:

Vials:

A single dose may be further diluted or initially diluted with 50 to 100 mL of D5W or NS. Also available in dual-chamber DUPLEX containers and pharmacy bulk packaging. Refer to manufacturer's prescribing information for specific preparation and storage requirements.

Filters:

No data available from manufacturer.

Storage:

Store vials below 22° C (72° F); protect from light. Administer within 24 hours of preparation or within 96 hours if refrigerated. Stable after dilution for 1 week if frozen; thaw at room temperature before use; discard remaining solution; do not refreeze. Slight yellowing does not affect potency.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer separately and flush the IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and states, "Do not add supplementary medications to premixed plastic IV containers" (e.g., Galaxy).

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Compatibility. May be given through Y-tube or three-way stopcock of infusion set.

IV injection:

A single dose equally distributed over 3 to 5 minutes.

Intermittent IV:

A single dose equally distributed over 30 minutes.

ACTIONS

A broad-spectrum, second-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Inhibits bacterial cell wall synthesis. Effective against many otherwise resistant organisms. Peak serum levels achieved at end of infusion. Widely distributed in most tissues, body fluids (CSF minimal), bone, gallbladder, myocardium, and skin and soft tissue. Half-life is from 3 to 4.6 hours. Primarily excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, gynecologic, intra-abdominal, and bone and joint infections. Most effective against specific organisms (see literature). ■ Perioperative prophylaxis.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins or related antibiotics (penicillins). Absolute only if reaction was serious and in patients who have experienced a cephalosporin-associated hemolytic anemia. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Specific sensitivity studies are indicated to determine susceptibility of the causative organism to cefotetan. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefotetan should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 or 3 days after all symptoms of infection subside. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, a history of GI disease (especially colitis), bleeding disorders or allergies, and those receiving an extended course of cephalosporins. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefotetan. ■ Hemolytic anemia, including fatalities, has been reported. Discontinue cefotetan immediately if anemia develops during the course of therapy. May present during treatment or up to 2 to 3 weeks following therapy completion.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Use extreme caution in the penicillin-sensitive patient; incidence of cross-sensitivity may be up to 10%. ■ May cause hypoprothrombinemia (deficiency of prothrombin [factor II]); 10 mg/week of prophylactic vitamin K may be indicated in elderly, debilitated, or other patients with vitamin K deficiency. Monitor PT. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Observe for electrolyte imbalance and cardiac irregularities. Contains 3.5 mEq sodium per Gm. ■ Monitor for S/S of hemolytic anemia, including CBC if indicated. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education:

Avoid alcohol or alcohol-containing preparations; may cause abdominal cramps, flushing, headache, nausea and vomiting, shortness of breath, sweating, and tachycardia. ■ Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy not established. Use only if clearly needed. ■ Use caution if breast-feeding. ■ Safety for use in pediatric patients not established. Immature renal function of infants and small children will increase blood levels of all cephalosporins.

Elderly:

See Dose Adjustments. ■ Safety and effectiveness similar to younger adults; however, greater sensitivity of some older individuals cannot be ruled out. ■ Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

May produce symptoms of acute intolerance with **alcohol** (a disulfiram-like reaction with abdominal cramps, headache, flushing, nausea and vomiting, shortness of breath, sweating, tachycardia). Patient must abstain from alcohol during treatment and until at least 72 hours after discontinuation. ■ Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics). ■ Sources differ on inhibition of excretion by **probenecid.** ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Bleeding tendency increased with **any medicine that affects blood clotting** (e.g., heparin and oral anticoagulants [warfarin], thrombolytic agents [e.g., alteplase (tPA)], salicylates, NSAIDs, sulfinpyrazone). ■ Large amounts of cephalosporins and/or salicylates may induce **hypoprothrombinemia.** ■ **False increases in creatinine levels** with Jaffe method. ■ **False-positive for urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ **Positive direct Coombs' test.** ■ See Compatibility and Side Effects.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis. Bleeding episodes; burning, discomfort, and pain at injection site; CDAD; diarrhea; elevated alkaline phosphatase, AST, ALT, and LDH; eosinophilia; nausea; prolonged PT; seizures (large doses); thrombocytosis. Hypoprothrombinemia (rare) and hemolytic anemia may occur.

ANTIDOTE

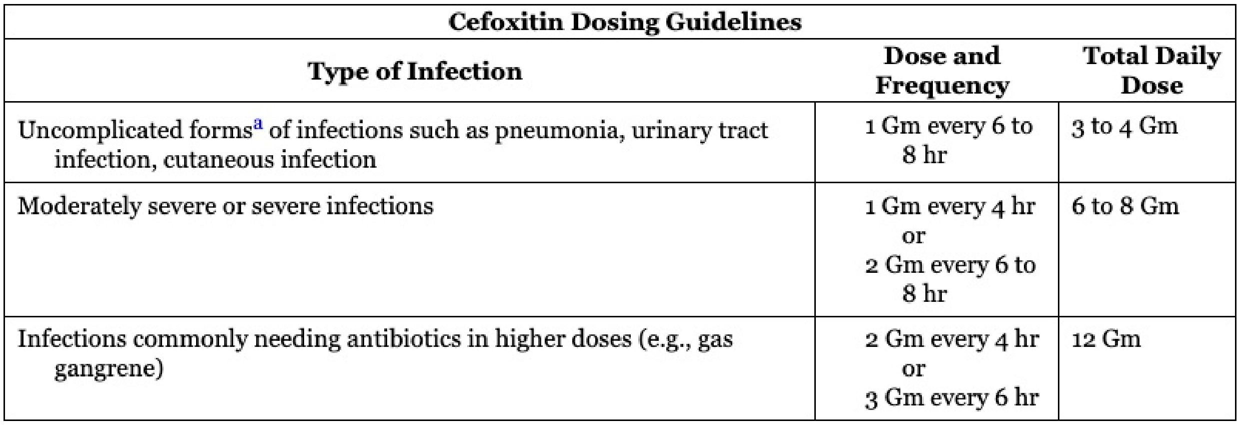
Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of cefotetan. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Bleeding episodes may respond to vitamin K or require discontinuation of drug. Fresh frozen plasma, packed red cells, or platelet concentrates may be indicated in abnormal bleeding tendencies confirmed by lab evaluations. If bleeding is due to platelet dysfunction, discontinue and use an alternate antibiotic. Blood transfusions (e.g., packed red cells) may be indicated if hemolytic anemia develops. Hemodialysis is only slightly useful in overdose.

CEFOXITIN SODIUM

(seh-**FOX**-ih-tin **SO**-dee-um)
Mefoxin
Antibacterial (cephalosporin)
pH 4.2 to 7

USUAL DOSE

Range is 1 to 2 Gm every 6 to 8 hours. Dose based on severity of disease, susceptibility of pathogens, and condition of patient.



Cefoxitin Dosing Guidelines

Type of Infection	Dose and Frequency	Total Daily Dose
Uncomplicated forms[a] of infections such as pneumonia, urinary tract infection, cutaneous infection	1 Gm every 6 to 8 hr	3 to 4 Gm
Moderately severe or severe infections	1 Gm every 4 hr or 2 Gm every 6 to 8 hr	6 to 8 Gm
Infections commonly needing antibiotics in higher doses (e.g., gas gangrene)	2 Gm every 4 hr or 3 Gm every 6 hr	12 Gm

[a] Including patients in whom bacteremia is absent or unlikely.

Perioperative prophylaxis:

2 Gm 30 minutes to 1 hour before incision. Follow with 2 Gm every 6 hours for no more than 24 hours.

Prophylaxis during cesarean section:

Either a single 2-Gm dose after clamping the umbilical cord or a 3-dose regimen consisting of 2 Gm given as soon as the umbilical cord is clamped followed by 2 Gm in 4 hours and again in 8 hours.

PEDIATRIC DOSE

Pediatric patients over 3 months of age:

Manufacturer recommends 80 to 160 mg/kg/24 hr divided into 4 to 6 equal doses (20 to 40 mg/kg every 6 hours or 13.3 to 26.7 mg/kg every 4 hours), with higher doses being used for more severe or serious infections. Other sources recommend: ***Mild to moderate infections:*** 80 mg/kg/24 hr in equally divided doses every 6 to 8 hours (20 mg/kg every 6 hours or 26.66 mg/kg every 8 hours). ***Severe infections:*** 160 mg/kg/24 hr in equally divided doses every 6 hours (40 mg/kg every 6 hours). Do not exceed adult dose and/or 12 Gm.

Perioperative prophylaxis in pediatric patients over 3 months of age:

30 to 40 mg/kg 30 minutes to 1 hour before incision and every 6 hours for no more than 24 hours.

NEONATAL DOSE (unlabeled)

Use sterile cefoxitin sodium USP only. Other formulations may contain benzyl alcohol.

90 to 100 mg/kg/24 hr in equally divided doses every 8 hours (30 to 33.3 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Reduced dose or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ In impaired renal function, the initial dose should be as previously listed, but all remaining maintenance doses should be based on CrCl according to the following chart. See Drug/Lab Interactions.

Cefoxitin Maintenance Dose in Adults With Impaired Renal Function		
Creatinine Clearance (mL/min)	**Dose (Gm)**	**Frequency**
30-50 mL/min	1-2 Gm	q 8-12 hr
10-29 mL/min	1-2 Gm	q 12-24 hr
5-9 mL/min	0.5-1 Gm	q 12-24 hr
<5 mL/min	0.5-1 Gm	q 24-48 hr

Hemodialysis patients should receive a loading dose of 1 to 2 Gm after each dialysis in addition to the maintenance dose listed in the previous chart.

In pediatric patients, **the manufacturer recommends reducing the dose and frequency consistent with the recommendations for adults.**

DILUTION

1 Gm of the lyophilized powder must be reconstituted with at least 10 mL, and 2 Gm with 10 or 20 mL, of SWFI, BWFI, D5W, or NS. May be given as an intermittent injection, or a single dose may be further diluted in 50 to 1,000 mL of most common infusion solutions (see chart on inside back cover and literature). The use of butterfly needles and dilution in up to 1,000 mL of D5W, D5NS, or NS are preferred when administering larger doses as a continuous infusion. Also available in dual-chamber DUPLEX containers and as a frozen, premixed solution. Refer to manufacturer's prescribing information for specific preparation and storage requirements. May be given through a Y-tube, three-way stopcock, additive infusion set, or as a continuous infusion.

Storage:

Storage before use is dependent on product. Reconstituted solutions are stable at RT for 6 hours and 7 days if refrigerated. Solutions diluted in 50 to 1,000 mL diluent are stable for an additional 18 hours at RT and an additional 48 hours if refrigerated.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer separately and flush the IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion. Do not introduce additives to the DUPLEX® container.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Dilution. Each 1 Gm or fraction thereof over 3 to 5 minutes or longer as indicated by amount of solution and condition of the patient. Intermittent infusions are commonly given over 30 minutes. Rate of continuous infusion should be by physician order.

ACTIONS

A semi-synthetic, second-generation cephalosporin antibiotic that is bactericidal to many gram-positive, gram-negative, and anaerobic organisms. Inhibits bacterial cell wall synthesis. Has activity in the presence of some beta-lactamases, both penicillinases and cephalosporinases, of gram-negative and gram-positive bacteria. Peak serum levels achieved by end of infusion. Widely distributed into many body tissues and fluids (CSF minimal). Passes into pleural and joint fluids and is detectable in antibacterial concentrations in bile. Half-life is 41 to 59 minutes. Excreted rapidly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory, urinary, intra-abdominal, gynecologic, bone and joint, skin and skin structure infections, and septicemia. Effective only if the causative organism is susceptible. If *C. trachomatis* is a suspected pathogen, antichlamydial coverage should be added. ■ Perioperative prophylaxis in patients undergoing uncontaminated gastrointestinal surgery, vaginal or abdominal hysterectomy, or cesarean section.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cefoxitin or other cephalosporins; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefoxitin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefoxitin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefoxitin. ■ Continue treatment for group A beta-hemolytic streptococcal infections for 10 days or more to decrease the risk of rheumatic fever or glomerulonephritis.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Use extreme caution in the penicillin-sensitive patient; cross-sensitivity has been reported. ■ Thrombophlebitis may result from prolonged or high dosage; use small needles and larger veins, and rotate infusion sites. ■ Periodic monitoring of CBC, SCr, and liver function tests is recommended during prolonged therapy. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education:

Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Safety and effectiveness for use in pediatric patients from birth to 3 months of age not established. ■ Do not use formulations containing benzyl alcohol in infants and children under 3 months. ■ Immature renal function will increase blood levels. ■ Eosinophilia and elevated AST associated with higher doses in infants and children.

Elderly:

Response similar to that seen in younger adults. Dose selection should be cautious; see Dose Adjustments. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide). ■ **Probenecid** inhibits excretion. Reduced dose of cefoxitin may be required with concomitant use. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Cephalosporins may enhance the anticoagulant effects of **vitamin K antagonists** (e.g., warfarin). ■ False-positive reaction for **urine glucose** has been reported with Clinitest reagent tablets. Glucose tests based on enzymatic glucose oxidase reactions (e.g., Clinistix) is recommended. ■ False increases in **creatinine levels** with Jaffe method. ■ False increases in **urinary 17-hydroxy-corticosteroids levels** have been reported with high concentrations of cefoxitin in the urine. ■ See Compatibility and Side Effects.

SIDE EFFECTS

Local site reactions (e.g., thrombophlebitis) are most common. Acute renal failure; anemia; CDAD; colitis; hypersensitivity reactions (including anaphylaxis, angioedema, dyspnea, eosinophilia, fever, flushing, interstitial nephritis, pruritus, rash [including exfoliative dermatitis and toxic epidermal necrolysis] urticaria); elevations in SCr and BUN; hypotension; jaundice; leukopenia; nausea and vomiting; neutropenia; oral thrush; phlebitis; possible exacerbation of myasthenia gravis; positive direct Coombs' test; prolonged PT; proteinuria; seizures (large doses); thrombocytopenia; and transient elevation of AST, ALT, and alkaline phosphatase have occurred. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Abdominal pain, agranulocytosis, aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, superinfection, toxic epidermal necrolysis, toxic nephropathy, and vaginitis have been reported with cephalosporin-class antibiotics.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions as indicated and resuscitate as necessary. Hemodialysis may be useful in overdose.

CEFTAROLINE FOSAMIL

(cef-**TAR**-oh-leen **FOS**-a-mil)
Teflaro
Antibacterial (cephalosporin)
pH 4.8 to 6.5

USUAL DOSE

Pretreatment:

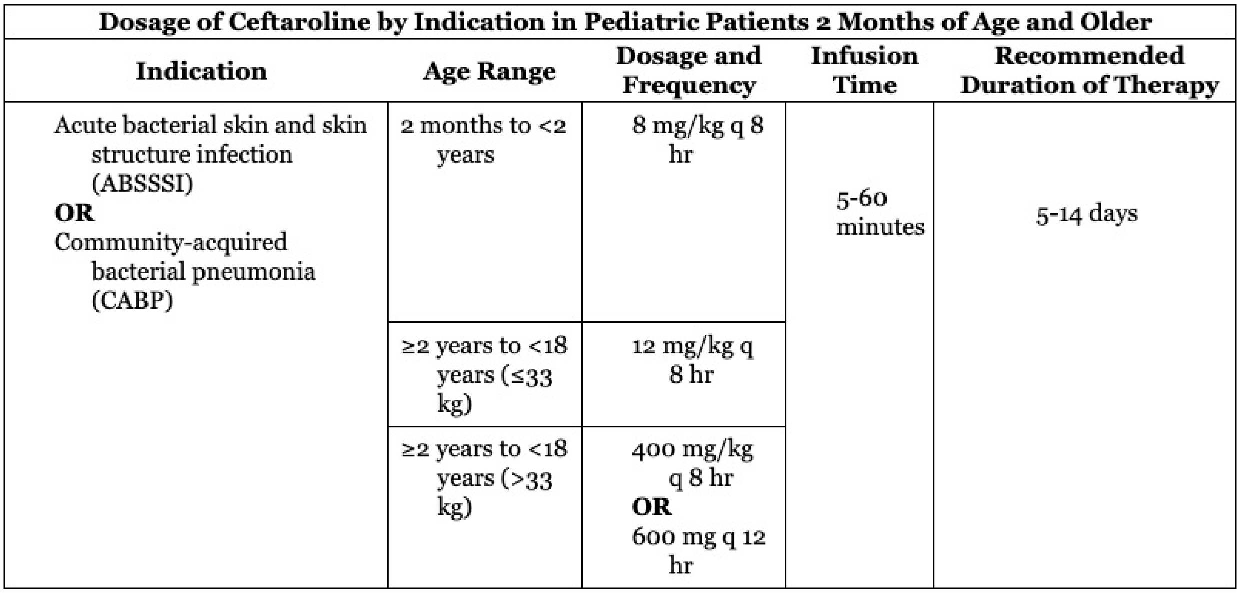
Baseline studies indicated; see Monitor.

Ceftaroline:

600 mg every 8-12 hours as an IV infusion over 5-60 minutes. Duration of therapy should be guided by the severity and the site of infection and the patient's clinical and bacteriologic progress.

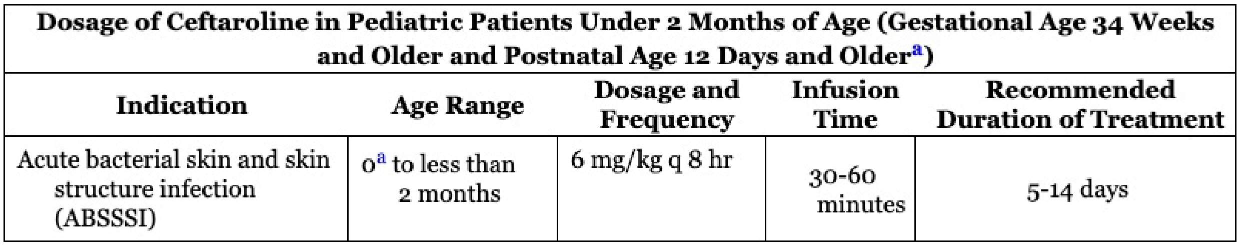
PEDIATRIC DOSE

Dosage is based on the age and weight of the child as outlined in the following charts. Duration of therapy should be guided by the severity and site of infection and the patient's clinical and bacteriologic progress.



Dosage of Ceftaroline by Indication in Pediatric Patients 2 Months of Age and Older

Indication	Age Range	Dosage and Frequency	Infusion Time	Recommended Duration of Therapy
Acute bacterial skin and skin structure infection (ABSSSI) **OR** Community-acquired bacterial pneumonia (CABP)	2 months to <2 years	8 mg/kg q 8 hr	5-60 minutes	5-14 days
	≥2 years to <18 years (≤33 kg)	12 mg/kg q 8 hr		
	≥2 years to <18 years (>33 kg)	400 mg/kg q 8 hr **OR** 600 mg q 12 hr		

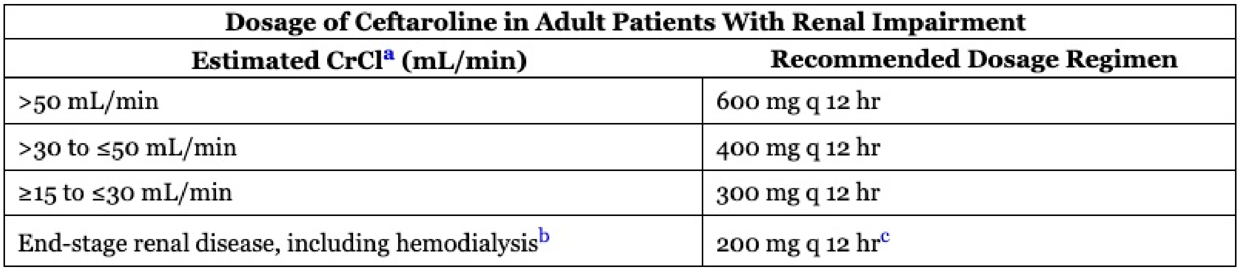


Dosage of Ceftaroline in Pediatric Patients Under 2 Months of Age (Gestational Age 34 Weeks and Older and Postnatal Age 12 Days and Older[a])				
Indication	**Age Range**	**Dosage and Frequency**	**Infusion Time**	**Recommended Duration of Treatment**
Acute bacterial skin and skin structure infection (ABSSSI)	0[a] to less than 2 months	6 mg/kg q 8 hr	30-60 minutes	5-14 days

[a] Gestational age 34 weeks and older and postnatal age 12 days and older.

DOSE ADJUSTMENTS

Dose adjustment required with renal impairment as outlined in the following chart.



Dosage of Ceftaroline in Adult Patients With Renal Impairment	
Estimated CrCl[a] (mL/min)	**Recommended Dosage Regimen**
>50 mL/min	600 mg q 12 hr
>30 to ≤50 mL/min	400 mg q 12 hr
≥15 to ≤30 mL/min	300 mg q 12 hr
End-stage renal disease, including hemodialysis[b]	200 mg q 12 hr[c]

[a] CrCl as calculated by Cockcroft-Gault formula.

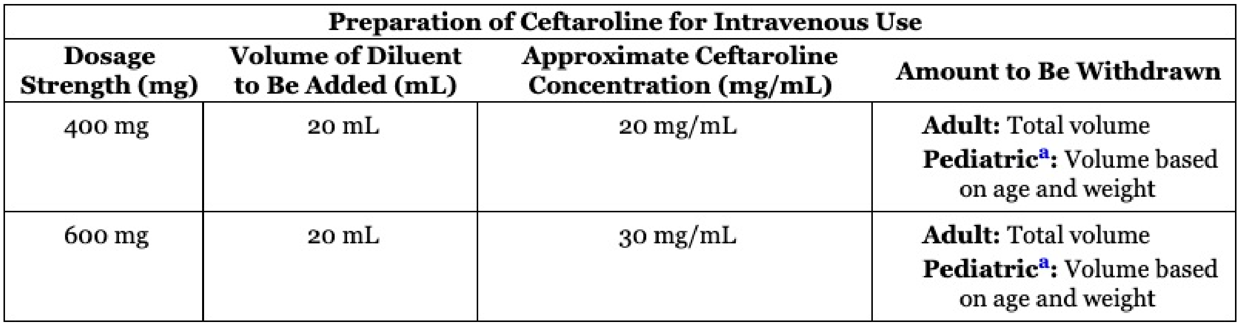
[b] End-stage renal disease is defined as CrCl <15 mL/min.

[c] Ceftaroline is hemodialyzable; administer after hemodialysis on hemodialysis days.

■ No dose adjustment is required in pediatric patients with CrCl >50 mL/min/1.73 M^2, estimated using the Schwartz equation. There is insufficient information to recommend a dosage regimen for pediatric patients with a CrCl <50 mL/min/1.73 M^2. ■ Dose adjustment is not indicated based on gender, race, or hepatic function. ■ Reduced dose may be indicated in the elderly based on age-related renal impairment.

DILUTION

Available in single-dose glass vials containing 600 mg or 400 mg. Reconstitute with 20 mL of SWFI, NS, D5W, or LR as shown in the following chart. Mix gently. Time to dissolution is less than 2 minutes.



Preparation of Ceftaroline for Intravenous Use			
Dosage Strength (mg)	**Volume of Diluent to Be Added (mL)**	**Approximate Ceftaroline Concentration (mg/mL)**	**Amount to Be Withdrawn**
400 mg	20 mL	20 mg/mL	**Adult:** Total volume **Pediatric**[a]**:** Volume based on age and weight
600 mg	20 mL	30 mg/mL	**Adult:** Total volume **Pediatric**[a]**:** Volume based on age and weight

[a]The recommended dosage of ceftaroline is based on the age and weight of the child.

Further dilute the reconstituted solution in 50 to 250 mL. Use the same diluent for further dilution unless SWFI was used. If SWFI was used as the initial diluent, further dilute the reconstituted solution in NS, D5W, D2.5/0.45NS, or LR.

Adults:

When preparing a 600-mg ceftaroline dose in a 50-mL infusion bag, withdraw 20 mL of the infusion solution before injecting the reconstituted drug into the bag. Resultant concentration approximately 12 mg/mL.

Adult or pediatric patients weighing more than 33 kg:

When preparing a 400-mg ceftaroline dose in a 50-mL infusion bag, withdraw 20 mL of the infusion solution before injecting the reconstituted drug into the bag. Resultant concentration approximately 8 mg/mL.

Pediatric patients weighing 33 kg or less:

When preparing a ceftaroline dose in a 50-mL infusion bag, the amount of solution withdrawn from the reconstituted ceftaroline vial will vary according to the weight and age of the child.

The final solution concentration should not exceed 12 mg/mL. Infusion solution ranges from clear light yellow to dark yellow depending on the concentration and the storage conditions.

Filter:

Data not available.

Storage:

Store unopened vials at CRT. Diluted solution should be used within 6 hours when stored at RT or within 24 hours when refrigerated.

COMPATIBILITY

Manufacturer states, “Should not be mixed with or physically added to solutions containing other drugs.” **Compatibility** with other drugs has not been established.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adults and pediatric patients 2 months of age and older:

A single dose equally distributed over 5 to 60 minutes.

Pediatric patients under 2 months of age:

A single dose equally distributed over 30 to 60 minutes.

ACTIONS

A semi-synthetic, broad-spectrum cephalosporin. Ceftaroline fosamil, a prodrug, is converted into the bioactive ceftaroline in plasma by a phosphatase enzyme. Bactericidal to many gram-negative and gram-positive organisms. Inhibits bacterial cell wall synthesis. Protein binding is minimal (20%). Ceftaroline undergoes hydrolysis, forming an inactive metabolite. Half-life is approximately 2.2 to 3 hours. Both ceftaroline and its metabolites are primarily eliminated by the kidneys.

INDICATIONS AND USES

Treatment of adults and pediatric patients (at least 34 weeks gestational age and 12 days postnatal age) with acute bacterial skin and skin structure infection (ABSSSI) caused by susceptible strains of microorganisms. ■ Treatment of adults and pediatric patients 2 months of age and older with community-acquired bacterial pneumonia (CABP) caused by susceptible strains of microorganisms.

CONTRAINDICATIONS

Known serious hypersensitivity to ceftaroline or other members of the cephalosporin class.

PRECAUTIONS

Hypersensitivity reactions, some fatal, and serious skin reactions have been reported in patients receiving beta-lactam antibiotics. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, carbapenems, or other allergens. Cross-sensitivity among beta-lactam antibacterial agents has been established; however, the actual incidence of cross-allergenicity is not established. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to ceftaroline. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftaroline should be used to treat or prevent only those infections proven or strongly suspected to be caused by susceptible bacteria. ■ Although cross-resistance may occur, some isolates resistant to other cephalosporins may be susceptible to ceftaroline. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftaroline. ■ Seroconversion from a negative to a positive direct Coombs' test occurred in approximately 10% of adult patients and in approximately 18% of pediatric patients in clinical trials. No adverse reactions representing hemolytic anemia were reported. If anemia develops during or after treatment with ceftaroline, drug-induced hemolytic anemia should be considered and diagnostic studies, including a direct Coombs' test, should be performed.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Obtain baseline CBC with differential and platelet count and SCr.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., rash, hives, wheezing, shortness of breath). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Safety for use during pregnancy not established; use only if clearly needed. ■ No data are available regarding the presence of ceftaroline in human milk, the effects of ceftaroline on breast-fed infants, or the effects on milk production; use caution. ■ Safety and effectiveness for use in pediatric patients at least 34 weeks gestational age and 12 days postnatal age for treatment of ABSSSI have been established. ■ Safety and effectiveness for use in pediatric patients less than 34 weeks gestational age and 12 days postnatal age for treatment of ABSSSI have not been established. ■ Safety and effectiveness for use in pediatric patients under 2 months of age for treatment of CABP have not been established.

Elderly:

No specific problems documented. Efficacy and safety appear similar to that seen in younger patients. Consider age-related renal impairment; see Dose Adjustments.

DRUG/LAB INTERACTIONS

No clinical drug-drug interaction studies have been conducted. There is minimal potential for drug-drug interactions between ceftaroline and CYP450 substrates, inhibitors, or inducers; drugs known to undergo active renal secretion; and drugs that may alter renal blood flow.

SIDE EFFECTS

The most common side effects occurring in both adult and pediatric patients were diarrhea, nausea, and rash. Additional side effects more commonly reported in pediatric patients included fever and vomiting. Hypersensitivity reactions were the most frequently reported serious side effects leading to discontinuation of therapy. Other less frequently reported side effects included CDAD, constipation, hypokalemia, increased transaminases (ALT, AST), phlebitis, seroconversion from a negative to a positive direct Coombs' test, and vomiting. Several other side effects were reported in less than 2% of the population studied.

Post-Marketing:

Agranulocytosis, eosinophilic pneumonia, leukopenia.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Discontinue ceftaroline for suspected drug-induced hemolytic anemia and initiate supportive therapy as indicated (e.g., transfusion). Mild cases of CDAD may respond to discontinuation of ceftaroline. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Ceftaroline is partially removed by hemodialysis.

CEFTAZIDIME

(sef-**TAY**-zih-deem)
Fortaz, Tazicef
Antibacterial (cephalosporin)
pH 5 to 8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Range is from 250 mg to 2 Gm every 8 to 12 hours. Dosage based on severity of infection, condition and renal function of the patient, and susceptibility of the causative organism.

Uncomplicated urinary tract infections:

250 mg every 12 hours.

Complicated urinary tract infections:

500 mg every 8 to 12 hours.

Uncomplicated pneumonia; mild skin and skin structure infections:

500 mg to 1 Gm every 8 hours.

Bone and joint infections:

2 Gm every 12 hours.

Severe or life-threatening infections (especially in immunocompromised patients), meningitis, serious gynecologic and intra-abdominal infections:

2 Gm every 8 hours.

Pseudomonal lung infections in cystic fibrosis patients (must have normal renal function):

30 to 50 mg/kg of body weight every 8 hours. Do not exceed 6 Gm/24 hr.

PEDIATRIC DOSE

Pediatric patients 1 month to 12 years of age:

30 to 50 mg/kg of body weight every 8 hours. Reserve higher doses for immunocompromised pediatric patients or for those with cystic fibrosis or meningitis. Do not exceed 6 Gm/24 hr.

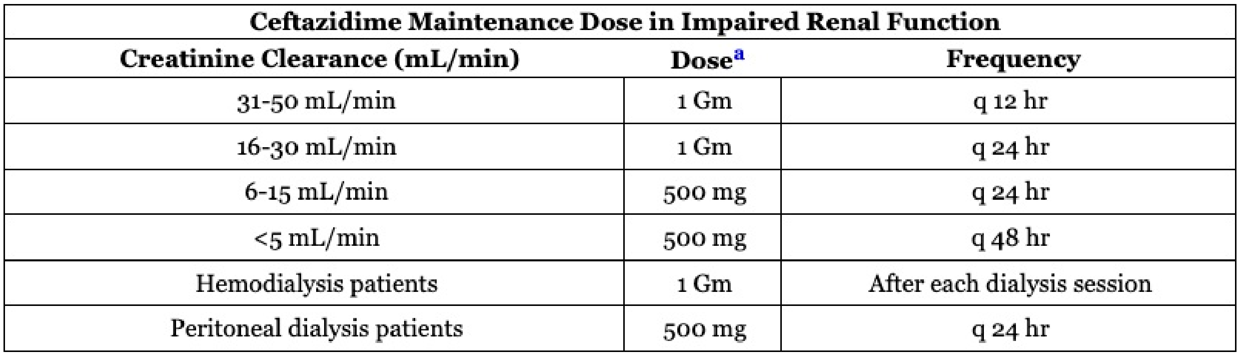
NEONATAL DOSE

Neonates up to 4 weeks of age:

30 mg/kg every 12 hours. Other dosing regimens based on age and weight are available in the pediatric literature.

DOSE ADJUSTMENTS

Reduced dose or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy. ■ In impaired renal function, an initial loading dose of 1 Gm may be given, but all remaining doses should be based on CrCl according to the following chart. Adjustment for pediatric patients is similar to adults; consider body surface area or lean body mass and reduce dosing frequency.



Ceftazidime Maintenance Dose in Impaired Renal Function

Creatinine Clearance (mL/min)	Dose[a]	Frequency
31-50 mL/min	1 Gm	q 12 hr
16-30 mL/min	1 Gm	q 24 hr
6-15 mL/min	500 mg	q 24 hr
<5 mL/min	500 mg	q 48 hr
Hemodialysis patients	1 Gm	After each dialysis session
Peritoneal dialysis patients	500 mg	q 24 hr

[a] If the normal dose would be lower than the doses in the chart, use the lower dose.

In patients with impaired renal function who have severe infection (normally requiring a 6 Gm/24 hr dose), the dose in the previous chart may be increased by 50% or the dosing frequency may be increased. In patients undergoing hemodialysis, give a loading dose of 1 Gm followed by 1 Gm after each dialysis. ■ In peritoneal dialysis patients (CAPD), give a loading dose of 1 Gm followed by 500 mg every 24 hours. In addition to IV use, ceftazidime can be incorporated in the dialysis fluid at a concentration of 250 mg for 2 L of dialysis fluid. ■ Dose reduction not required in impaired hepatic function.

DILUTION

IV injection:

Directions for the initial preparation of ceftazidime solutions are outlined in the following chart.

Preparation of Ceftazidime Solutions[a]			
Size	Amount of Diluent to Be Added (mL)	Approximate Available Volume (mL)	Approximate Ceftazidime Concentration (mg/mL)
500-mg vial	5.3	5.7[b]	100
1-Gm vial	10	10.8[c]	100
2-Gm vial	10	11.5[d]	170

[a] Directions may vary slightly depending on manufacturer. Consult prescribing information for product-specific reconstitution and dilution instructions.

[b] To obtain a dose of 500 mg, withdraw 5 mL from vial after reconstitution.

[c] To obtain a dose of 1 Gm, withdraw 10 mL from vial after reconstitution.

[d] To obtain a dose of 2 Gm, withdraw 11.5 mL from vial after reconstitution.

Reconstitute with SWFI as outlined in the chart. Shake well. Dilution generates CO_2. Invert vial and completely depress plunger of syringe. Insert needle through stopper and keep it within the solution. Expel bubbles from solution in syringe before injection.

Intermittent IV infusion:

A single dose may be further diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solutions for injection (see literature or chart on inside back cover).

Storage:

Store unopened vials in carton at CRT. Protect from light. Stability of reconstituted and diluted solution is product specific; consult manufacturer’s prescribing information. Selected products may be frozen for up to 3 months after initial dilution; thaw at room temperature (see instructions); do not refreeze. Will be light yellow to amber in color depending on concentration and diluent.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin, and tobramycin), but these drugs must never be mixed in the same infusion (mutual inactivation). May exhibit a physical **incompatibility** with vancomycin depending on concentration. If aminoglycosides or vancomycin are given concurrently, administer separately and flush IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and states, “Do not add supplementary medications to premixed plastic IV containers.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Compatibility. May be given through Y-tube or three-way stopcock of infusion set.

IV injection:

A single dose equally distributed over 3 to 5 minutes.

Intermittent IV infusion:

A single dose over 15 to 30 minutes. May also be given (off label) as extended infusion: IV 2 gm every 8 hours over 3-4 hours or my continuous infusion: 6 gm infused over 24 hours. May give first 2 gm dose over 30 minutes before starting infusion.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms, including *Pseudomonas aeruginosa*. Inhibits bacterial cell wall synthesis and has activity in the presence of some beta-lactamases of gram-negative and gram-positive bacteria. Peak serum levels achieved by end of infusion. Therapeutic levels distributed into many body fluids and tissues, including CSF and aqueous humor. Half-life is 1.9 hours. Excreted unchanged in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of the following infections caused by susceptible isolates of the designated microorganisms (see prescribing information): lower respiratory tract, urinary tract, skin and skin structure, bone and joint, gynecologic, intra-abdominal, CNS infections (including meningitis), and bacterial septicemia. Has been used alone in cases of confirmed or suspected sepsis and in combination with other antibacterial drugs such as aminoglycosides, vancomycin, and clindamycin in severe and life-threatening infections and in immunocompromised patients.

CONTRAINDICATIONS

History of hypersensitivity reaction to ceftazidime or the cephalosporin class of antibiotics; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Hypersensitivity reactions have been reported with administration of corn-derived, dextrose-containing products in patients with or without a history of hypersensitivity to corn products. Ceftazidime in the DUPLEX container contains dextrose. ■ Specific sensitivity studies indicated to determine susceptibility of causative organism to ceftazidime. Inducible type I beta-lactamase resistance has been noted with some organisms and can develop during therapy, leading to clinical failure. Periodic susceptibility testing may be indicated. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftazidime should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ Use with caution in patients with renal impairment. Elevated levels of ceftazidime in these patients can lead to asterixis, coma, encephalopathy, myoclonus, neuromuscular excitability, and seizures; see Dose Adjustments. ■ May be associated with a fall in prothrombin activity. Patients at risk include those with renal or hepatic impairment, those with poor nutritional status, and those receiving a protracted course of antimicrobial therapy. See Monitor. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with a history of GI disease (especially colitis). ■ An immune-mediated hemolytic anemia has been reported in patients receiving cephalosporin class antibiotics, including ceftazidime. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftazidime. ■ Continue for at least 2 days after all symptoms of infection subside.

Monitor:

Obtain baseline and periodic CBC and SCr. ■ Watch for early symptoms of a hypersensitivity reaction. ■ Monitor PT and administer vitamin K as indicated; see Precautions. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education:

Report promptly any bleeding or bruising, symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash), or neurologic symptoms (e.g., confusion, myoclonus, seizures). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. Use caution. ■ Immature renal function of infants and small children will increase blood levels of all cephalosporins. ■ Only specific solutions can be used in pediatric patients.

Elderly:

No specific differences in safety or effectiveness were observed between elderly and younger patients. ■ See Usual Dose and Dose Adjustments.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity and ototoxicity may be increased with **aminoglycosides and other nephrotoxic and/or ototoxic agents** (e.g., loop diuretics such as furosemide). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ **Probenecid** inhibits excretion of ceftazidime and may increase serum concentrations. ■ Cephalosporins may enhance the anticoagulant effects of **vitamin K antagonists** (e.g., warfarin). ■ May reduce the effectiveness of **oral estrogen/progesterone contraceptives.** ■ May have a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ See Compatibility and Side Effects.

SIDE EFFECTS

The most common adverse reactions occurring in fewer than 2% of patients include hypersensitivity reactions, GI symptoms, and CNS reactions. Full scope of hypersensitivity reactions (including anaphylaxis, bronchospasm, cardiopulmonary arrest, hypotension); abdominal pain; angioedema; burning, discomfort, and pain at injection site; candidiasis; CDAD; colitis; diarrhea; dizziness; elevated alkaline phosphatase, AST, ALT, GGT, and BUN/SCr; erythema multiforme; fever; headache; nausea and vomiting; paresthesia; phlebitis; prolonged PT; pruritus; rash; renal impairment; seizures (large doses or in patients with renal impairment); Stevens-Johnson syndrome; toxic epidermal necrolysis; toxic nephropathy; urticaria; vaginitis. Hypoprothrombinemia (rare) and hemolytic anemia may occur. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Overdose:

Asterixis, coma, encephalopathy, neuromuscular excitability, and seizures may occur in patients with renal impairment; see Precautions.

Post-Marketing:

Hyperbilirubinemia, jaundice.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reaction as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftazidime. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis may be useful in overdose.

CEFTAZIDIME/AVIBACTAM

(sef-**TAY**-zih-deem a-vih-**BAK**-tam)
Avycaz
Antibacterial
(cephalosporin/beta-lactamase inhibitor)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

18 years of age or older:

2.5 Gm (2 Gm ceftazidime/0.5 Gm avibactam) every 8 hours as an infusion over 2 hours.

PEDIATRIC DOSE

Dose of Ceftazidime/Avibactam in Patients 3 Months to Less Than 18 Years of Age

Infection	Age Range	Dose	Frequency	Infusion Time (hours)	Duration of Treatment
cIAI[a] and cUTI including Pyelonephritis	2 years to less than 18 years[b]	62.5 mg/kg to a maximum of 2.5 Gm (Ceftazidime 50 mg/kg and avibactam 12.5 mg/kg to a maximum dose of ceftazidime 2 Gm and avibactam 0.5 Gm)	Every 8 hours	2	cIAI: 5 to 14 days cUTI: 7 to 14 days
	6 months to less than 2 years	62.5 mg/kg (Ceftazidime 50 mg/kg and avibactam 12.5 mg/kg)			
	3 months to less than 6 months	50 mg/kg (Ceftazidime 40 mg/kg and avibactam 10 mg/kg)			

[a] Ceftazidime/avibactam was used in combination with metronidazole in cIAI pediatric patients in clinical studies (metronidazole dose used was 10 mg/kg q 8 hr).

[b] For pediatric patients (2 years or older) with eGFR ≤50 mL/min/1.73 M^2, dosage adjustments are recommended; see Dose Adjustments.

DOSE ADJUSTMENTS

No dose adjustment is recommended based on age, gender, or hepatic impairment. ■ Reduced dose may be indicated in the elderly based on age-related renal impairment. ■ Dose adjustment required for patients with moderate and severe renal impairment and end-stage renal disease according to the following charts.

Ceftazidime-Avibactam Dosing in Adult Patients With Renal Impairment	
Estimated CrCl (mL/min)	**Recommended Dose Regimen**
>50 mL/min	2.5 Gm (2 Gm/0.5 Gm) IV every 8 hours.
31 to 50 mL/min	1.25 Gm (1 Gm/0.25 Gm) IV every 8 hours.
16 to 30 mL/min	0.94 Gm (0.75 Gm/0.19 Gm) IV every 12 hours.
6 to 15 mL/min[a]	0.94 Gm (0.75 Gm/0.19 Gm) IV every 24 hours.
≤5 mL/min[a]	0.94 Gm (0.75 Gm/0.19 Gm) IV every 48 hours.

[a] Both ceftazidime and avibactam are hemodialyzable; administer after hemodialysis on hemodialysis days.

Ceftazidime-Avibactam Dosing in Pediatric Patients 2 Years and Older With Renal Impairment[a]		
Estimated eGFR[b] (mL/min/1.73M^2)	**Dose**	**Frequency**
31 to 50 mL/min	31.25 mg/kg to a maximum of 1.25 Gm (ceftazidime 25 mg/kg and avibactam 6.25 mg/kg to a maximum dose of ceftazidime 1 Gm and avibactam 0.25 Gm)	Every 8 hours
16 to 30 mL/min	23.75 mg/kg to a maximum of 0.94 Gm (ceftazidime 19 mg/kg and avibactam 4.75 mg/kg to a maximum dose of ceftazidime 0.75 Gm and avibactam 0.19 Gm)	Every 12 hours
6 to 15 mL/min	23.75 mg/kg to a maximum of 0.94 Gm (ceftazidime 19 mg/kg and avibactam 4.75 mg/kg to a maximum dose of ceftazidime 0.75 Gm and avibactam 0.19 Gm)	Every 24 hours
≤5 mL/min[c]	23.75 mg/kg to a maximum of 0.94 Gm (ceftazidime 19 mg/kg and avibactam 4.75 mg/kg to a maximum dose of ceftazidime 0.75 Gm and avibactam 0.19 Gm)	Every 48 hours

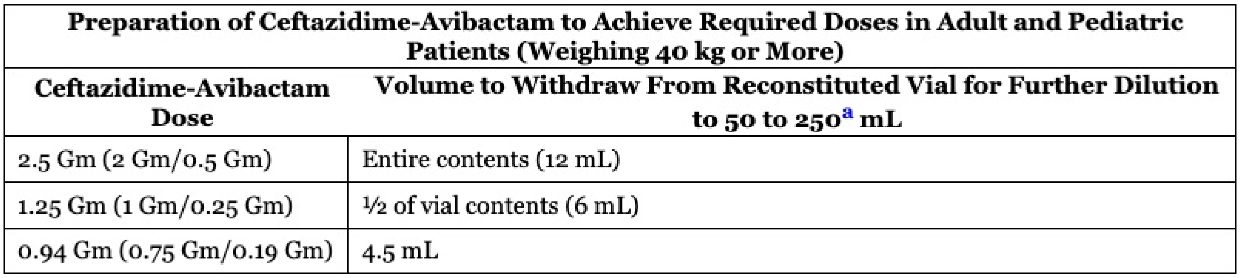
[a] Dosing was derived based on the population PK modeling, which assumed similar proportional effects of renal impairment in adults and pediatric patients 2 years of age and older.

[b] As calculated using the Schwartz bedside formula.

[c] Both ceftazidime and avibactam are hemodialyzable; administer after hemodialysis on hemodialysis days.

DILUTION

Available as single-use vials containing 2 Gm ceftazidime and 0.5 Gm avibactam. Reconstitute each vial with 10 mL of SWFI, NS, D5W, all combinations of dextrose and sodium chloride injection containing up to 2.5% dextrose and 0.45% NS, or LR injection. Mix gently. Reconstituted solution will have an approximate final volume of 12 mL, an approximate ceftazidime concentration of 167 mg/mL, and an approximate avibactam concentration of 42 mg/mL. Must be further diluted before infusion. Withdraw the required dose from the vial according to the following chart and transfer into an infusion bag containing the same diluent used for reconstitution of the powder (except SWFI) to achieve a final ceftazidime concentration of 8 to 40 mg/mL and a final avibactam concentration of 2 to 10 mg/mL. If SWFI was used for reconstitution, use any of the other appropriate diluents listed previously for dilution.



Preparation of Ceftazidime-Avibactam to Achieve Required Doses in Adult and Pediatric Patients (Weighing 40 kg or More)	
Ceftazidime-Avibactam Dose	**Volume to Withdraw From Reconstituted Vial for Further Dilution to 50 to 250[a] mL**
2.5 Gm (2 Gm/0.5 Gm)	Entire contents (12 mL)
1.25 Gm (1 Gm/0.25 Gm)	½ of vial contents (6 mL)
0.94 Gm (0.75 Gm/0.19 Gm)	4.5 mL

[a] Dilution to 250 mL should be used only for the 2.5-Gm dose.

To prepare doses for pediatric patients weighing less than 40 kg, follow the constitution instruction in the previous chart to yield a solution with a final ceftazidime-avibactam concentration of approximately 209 mg/mL (ceftazidime concentration of 167 mg/mL and avibactam concentration of 42 mg/mL). Use these concentrations to calculate the volume of ceftazidime-avibactam required to prepare the prescribed dose. Ensure that contents are completely dissolved. Infusion solution ranges from clear to light yellow.

Filters:

Specific information not available.

Storage:

Before use, store at CRT in original carton to protect from light. The reconstituted solution may be held for no longer than 30 minutes before dilution in a suitable infusion solution. Fully diluted solutions may be stored for 12 hours at room temperature or for 24 hours refrigerated at 2° to 8° C (36° to 46° F). Use refrigerated solution within 12 hours of subsequent storage at RT.

COMPATIBILITY

Manufacturer states **compatible** with the more commonly used IV infusion fluids in infusion bags (including Baxter Mini-Bag Plus); see Dilution. Simulated **Y-site compatibility** studies using a solution of ceftazidime and avibactam at concentrations of 20 mg/mL and 5 mg/mL, respectively, were performed. **Compatible** drugs with the corresponding **compatible** diluent (D5W, NS, or LR) include amikacin, azithromycin, aztreonam, ceftaroline, colistimethate, daptomycin, dexmedetomidine, dopamine, furosemide, gentamicin, imipenem-cilastatin, levofloxacin, magnesium sulfate, metronidazole, norepinephrine, phenylephrine, vasopressin, and vecuronium. Depending on the diluent, the following drugs may also be **compatible** at the **Y-site** (see prescribing information for specific information): ertapenem, heparin, linezolid, meropenem, potassium chloride, potassium phosphates, sodium bicarbonate, tedizolid, and tobramycin.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 2 hours.

ACTIONS

Ceftazidime-avibactam is an antibacterial combination product consisting of the cephalosporin ceftazidime pentahydrate and the beta-lactamase inhibitor avibactam sodium. Ceftazidime is a cephalosporin antibacterial drug with in vitro activity against certain gram-negative and gram-positive bacteria. Active against several gram-negative bacteria in clinical infections. Its bactericidal action results from inhibition of cell wall biosynthesis and is mediated through binding to penicillin-binding proteins (PBPs). Avibactam is a non–beta-lactam beta-lactamase inhibitor that inactivates certain beta-lactamases that degrade ceftazidime. Less than 10% of ceftazidime is protein bound. Both ceftazidime and avibactam are excreted mainly by the kidneys, primarily as unchanged drug. Terminal half-life is approximately 2.8 hours. Ceftazidime is excreted in human milk in low concentrations.

INDICATIONS AND USES

Treatment of infections caused by susceptible isolates of designated organisms in the conditions and patient populations listed below. ■ Used in combination with metronidazole for the treatment of complicated intra-abdominal infections (cIAI) in adult and pediatric patients 3 months of age or older. ■ Treatment of complicated urinary tract infections (cUTI), including pyelonephritis, in adult and pediatric patients 3 months of age or older. ■ Treatment of hospital-acquired bacterial pneumonia and ventilator-associated bacterial pneumonia (HABP/VABP) in patients 18 years of age or older.

CONTRAINDICATIONS

Known serious hypersensitivity to ceftazidime-avibactam, ceftazidime, avibactam-containing products, or other members of the cephalosporin class.

PRECAUTIONS

For IV infusion only; do not administer as an IV bolus. ■ In a cIAI trial, clinical cure rates were lower in a subgroup of patients with a baseline CrCl of 30 mL/min to less than or equal to 50 mL/min compared with patients with a CrCl of greater than 50 mL/min. Reduction in clinical cure rates was more marked in patients treated with ceftazidime-avibactam plus metronidazole compared with meropenem-treated patients. Within this subgroup, patients treated with ceftazidime/avibactam received a 33% lower daily dose than is currently recommended for patients with a CrCl of 30 mL/min to less than or equal to 50 mL/min; see Monitor. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions and serious skin reactions have been reported in patients receiving beta-lactam antibacterial drugs. Check history of previous hypersensitivity reactions to other cephalosporins, penicillins, or carbapenems. Cross-sensitivity among beta-lactam antibacterial drugs has been established. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to ceftazidime-avibactam. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftazidime-avibactam should be used to treat only those infections proven or strongly suspected to be caused by susceptible bacteria. ■ No cross-resistance with other classes of antimicrobials has been identified. Some isolates resistant to other cephalosporins (including ceftazidime) and to carbapenems may be susceptible to ceftazidime-avibactam. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported for nearly all systemic antibacterial agents and may range in severity from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftazidime-avibactam. ■ Central nervous system reactions (e.g., asterixis, coma, encephalopathy, myoclonia, neuromuscular excitability, nonconvulsive status epilepticus, and seizures) have been reported in patients treated with ceftazidime, particularly in patients with renal impairment. Adjust dose based on CrCl.

Monitor:

Obtain baseline and periodic SCr. Monitor CrCl at least daily in patients with changing renal function. Adjust dose of ceftazidime-avibactam accordingly; see Dose Adjustments. ■ Monitor for S/S of a hypersensitivity reaction (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing).

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report neurologic S/S (e.g., encephalopathy [disturbance of consciousness including confusion, hallucinations, stupor, and coma], myoclonus, and seizures). ■ Full course of therapy must be completed.

Maternal/Child:

Use during pregnancy only if clearly needed. ■ No information is available on the effects of ceftazidime and avibactam on breast-fed pediatric patients or on milk production; use caution during breast-feeding. ■ Safety and effectiveness in the treatment of cIAI and cUTI have been established in pediatric patients 3 months to less than 18 years of age. Safety and effectiveness in pediatric patients under 3 months of age with cIAI or cUTI have not been established. Safety and effectiveness in patients under 18 years of age with HABP/VABP have not been established.

Elderly:

Incidence of side effects may be higher in elderly patients being treated for cIAI. This finding was not identified in the cUTI or HABP/VABP trials. ■ Consider age-related renal impairment, monitoring of renal function, and dose with caution; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Formal drug interaction studies have not been conducted. ■ In vitro, avibactam is a substrate of OAT1 and OAT3. Coadministration with **probenecid** prolongs the half-life of avibactam and is not recommended. ■ In vitro studies have not demonstrated antagonism between ceftazidime-avibactam and colistin, levofloxacin (Levaquin), linezolid (Zyvox), metronidazole (Flagyl), tigecycline (Tygacil), tobramycin, or vancomycin. ■ May have a false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix).

SIDE EFFECTS

The most common side effects reported in adults are diarrhea, nausea, and vomiting. The most common side effects reported in pediatric patients are diarrhea, infusion site phlebitis, rash, and vomiting. The safety profile of ceftazidime-avibactam in pediatric patients is similar to adults with cIAI and cUTI. Hypersensitivity reactions, skin reactions, central nervous system reactions, and CDAD may be severe. Other reported side effects include abdominal pain, constipation, dizziness, headache, pruritus, and upper abdominal pain. Other side effects have been reported in fewer than 1% of patients.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftazidime-avibactam. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Both ceftazidime and avibactam can be removed from the circulation by hemodialysis.

CEFTOLOZANE/TAZOBACTAM

(sef-**TOL**-oh-zane/**TAZ**-oh-**BAK**-tam)
Zerbaxa
Antibacterial (cephalosporin/beta-lactamase inhibitor)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.
1.5 Gm (ceftolozane 1 Gm and tazobactam 0.5 Gm) to 3 Gm (ceftolozane 2 Gm and tazobactam 1 Gm) every 8 hours as an infusion over 1 hour. Guide duration of treatment by the severity and site of the infection and the patient’s clinical and bacteriologic progress.

DOSE ADJUSTMENTS

No dose adjustment is recommended based on age, gender, hepatic impairment, or race. ■ Dose adjustment is required for patients with a CrCl of 50 mL/min or less according to the following chart.

Ceftolozane/Tazobactam Dosing in Patients With Renal Impairment

Estimated CrCl (mL/min)	Complicated Intra-abdominal Infections and Complicated Urinary Tract Infections, Including Pyelonephritis	Hospital-Acquired Bacterial Pneumonia and Ventilator-Associated Bacterial Pneumonia
30 to 50 mL/min	750 mg (500 mg and 250 mg) IV every 8 hours	1.5 Gm (1 Gm and 0.5 Gm) IV every 8 hours
15 to 29 mL/min	375 mg (250 mg and 125 mg) IV every 8 hours	750 mg (500 mg and 250 mg) IV every 8 hours
End-stage renal disease (ESRD) on hemodialysis (HD)	A single loading dose of 750 mg (500 mg and 250 mg) followed by a 150 mg (100 mg and 50 mg) maintenance dose administered every 8 hours for the remainder of the treatment period (on hemodialysis days, administer the dose at the earliest possible time following completion of dialysis)	A single loading dose of 2.25 Gm (1.5 Gm and 0.75 Gm) followed by a 450 mg (300 mg and 150 mg) maintenance dose administered every 8 hours for the remainder of the treatment period (on hemodialysis days, administer the dose at the earliest possible time following completion of dialysis)

DILUTION

Available as single-dose vials containing 1 Gm ceftolozane and 0.5 Gm tazobactam. Reconstitute each vial with 10 mL of SWFI or NS and gently shake to dissolve. Final volume is approximately 11.4 mL. Reconstituted solution is ***NOT*** for direct injection.

Withdraw the required dose from the vial(s) according to the following chart and transfer to an infusion bag containing 100 mL of NS or D5W.

Preparation of Ceftolozane/Tazobactam to Achieve Required Doses	
Ceftolozane/Tazobactam Dose	**Volume to Withdraw From Reconstituted Vial(s)**
3 Gm (2 Gm and 1 Gm)	Two vials of 11.4 mL each (entire contents from 2 vials)
2.25 Gm (1.5 Gm and 0.75 Gm)	11.4 mL for one vial (entire contents) and 5.7 mL from a second vial
1.5 Gm (1 Gm and 0.5 Gm)	11.4 mL (entire contents)
750 mg (500 mg and 250 mg)	5.7 mL
450 mg (300 mg and 150 mg)	3.5 mL
375 mg (250 mg and 125 mg)	2.9 mL
150 mg (100 mg and 50 mg)	1.2 mL

Infusion solutions range from clear, colorless solutions to clear and slightly yellow.

Filters:

Specific information not available.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. Solutions reconstituted with SWFI or NS may be held for 1 hour before transfer and dilution. Fully diluted solutions may be stored for 24 hours at room temperature or for 7 days if refrigerated. Do not freeze reconstituted or diluted solutions.

COMPATIBILITY

Compatibility with other drugs not established. Manufacturer states, “Ceftolozane/tazobactam should not be mixed with other drugs or physically added to solutions containing other drugs.”

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 1 hour (per manufacturer); some reference suggest the 3 gm dose be administerd over 3 hours.

ACTIONS

Ceftolozane/tazobactam is an antibacterial combination product consisting of the cephalosporin antibacterial drug ceftolozane sulfate and the beta-lactamase inhibitor tazobactam sodium. Its bactericidal action results from inhibition of cell wall biosynthesis and is mediated through binding to penicillin-binding proteins (PBPs). Tazobactam sodium is an irreversible inhibitor of some beta-lactamases (enzymes [e.g., certain penicillinases and cephalosporinases] produced by bacteria and capable of hydrolyzing/inactivating penicillins and cephalosporins). Active against a variety of gram-negative, gram-positive, and anaerobic bacteria. Protein binding of ceftolozane and tazobactam is approximately 16% to 21% and 30%, respectively. Ceftolozane does not appear to be metabolized to an appreciable extent. Tazobactam is hydrolyzed to an inactive metabolite. Half-life of ceftolozane is approximately 3 to 4 hours. Half-life of tazobactam is approximately 2 to 3 hours. Both ceftolozane and tazobactam are eliminated by the kidneys—ceftolozane as the unchanged parent drug and tazobactam as the unchanged parent drug and its inactive metabolite.

INDICATIONS AND USES

Treatment of patients 18 years of age or older with infections caused by susceptible isolates of designated organisms in the conditions listed below. ■ Used in combination with metronidazole for the treatment of complicated intra-abdominal infections (cIAI). ■ Treatment of complicated urinary tract infections (cUTI), including pyelonephritis. ■ Treatment of hospital-acquired bacterial pneumonia and ventilator-associated bacterial pneumonia (HABP/VABP).

CONTRAINDICATIONS

Known serious hypersensitivity to ceftolozane/tazobactam, piperacillin/tazobactam, or other members of the beta-lactam class.

PRECAUTIONS

For IV infusion only; do not administer as an IV bolus. ■ Decreased efficacy was seen in cIAI and cUTI trials in patients with a baseline CrCl of 30 to 50 mL/min; see Monitor. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported in patients receiving beta-lactam antibacterial drugs. Check the history of previous hypersensitivity reactions to penicillins, cephalosporins, or other beta-lactam antibacterial drugs. Cross-sensitivity has been established. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to ceftolozane/tazobactam. ■ Bacteria resistant to other cephalosporins may be susceptible to ceftolozane/tazobactam, although cross-resistance may occur. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftolozane/tazobactam should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported for nearly all systemic antibacterial agents and may range in severity from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftolozane/tazobactam.

Monitor:

Monitor the CrCl at least daily in patients with changing renal function. Adjust dose of ceftolozane/tazobactam accordingly. ■ Monitor for S/S of a hypersensitivity reaction (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing).

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use during pregnancy only if the potential benefit outweighs the possible risk. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

A higher incidence of adverse reactions occurs in patients 65 years of age and older. ■ In the complicated intra-abdominal infection clinical trial, cure rates were lower in patients 65 years of age or older in the ceftolozane/tazobactam group compared with the comparator group. This finding in the elderly population was not seen in the complicated UTI trial. ■ Consider age-related renal impairment, monitoring of renal function, and dose with caution; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Ceftolozane/tazobactam is not metabolized in the liver. No significant drug-drug interactions are anticipated between ceftolozane/tazobactam and substrates, inhibitors, and inducers of cytochrome P_{450} enzymes. ■ It is not a substrate for P-glycoprotein (P-gp). ■ Tazobactam is a known substrate for OAT1 and OAT3. Coadministration with the OAT1/OAT3 inhibitor **probenecid** prolongs the half-life of tazobactam by 71%.

SIDE EFFECTS

The most common side effects reported in either cIAI or cUTI are diarrhea, fever, headache, and nausea. The most common side effects reported in HABP/VABP are diarrhea, increase in hepatic transaminases, and renal impairment/renal failure. Hypersensitivity reactions and CDAD may be severe. Other reported side effects include abdominal pain, anemia, anxiety, atrial fibrillation, constipation, dizziness, hypokalemia, hypotension, increased ALT and AST, insomnia, intracranial hemorrhage, rash, thrombocytosis, and vomiting. Other side effects have been reported in fewer than 1% of patients.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftolozane/tazobactam. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Both ceftolozane and tazobactam are partially removed by hemodialysis.

CEFTRIAXONE SODIUM

(sef-try-**AX**-ohn **SO**-dee-um)
Rocephin
Antibacterial (cephalosporin)
pH 6.6 to 6.7

USUAL DOSE

Adults and pediatric patients over 12 years:

1 to 2 Gm/24 hr. May be given as a single dose every 24 hours or equally divided into 2 doses and given every 12 hours depending on the type and severity of the infection. Do not exceed a total dose of 4 Gm/24 hr.

Meningitis:

2 Gm every 12 hours.

Disseminated gonococcal infections (unlabeled):

1 Gm daily for 24 to 48 hours. Transfer to oral dosing after improvement is noted, and continue for a total of 7 days of therapy.

Perioperative prophylaxis:

1 Gm IV 30 minutes to 2 hours before incision. Used primarily in patients undergoing coronary artery bypass surgery and in contaminated or potentially contaminated surgeries.

Lyme disease (unlabeled):

2 Gm daily for 14 days (range 14 to 28 days).

PEDIATRIC DOSE

See Maternal/Child.

Pediatric patients 1 month to 12 years of age:

Skin and soft tissue:

50 to 75 mg/kg of body weight/24 hr as a single dose or in equally divided doses every 12 hours (25 to 37.5 mg/kg every 12 hours). Do not exceed a total dose of 2 Gm/24 hr.

Other serious infections (other than meningitis):

50 to 75 mg/kg of body weight/24 hr in equally divided doses every 12 hours (25 to 37.5 mg/kg every 12 hours). Do not exceed a total dose of 2 Gm/24 hr.

Bacterial meningitis:

Begin with a loading dose of 100 mg/kg on day 1 (do not exceed a total dose of 4 Gm), follow with 100 mg/kg/day (not to exceed 4 Gm) as a single dose or in equally divided doses every 12 hours (50 mg/kg every 12 hours). Continue for 7 to 14 days depending on the causative organism.

Lyme disease (unlabeled):

50 to 75 mg/kg/day for 14 days (range 10 to 28 days). Maximum dose is 2 Gm.

NEONATAL DOSE

See Contraindications, Rate of Administration, and Maternal/Child before administration to neonates.

Neonatal doses may also be given IM.

The American Academy of Pediatrics (AAP) recommends the following:

28 days of age or younger regardless of weight:

50 mg/kg/day as a single daily dose.

Bacterial meningitis:

Same as Pediatric Dose.

Infants born to mothers with gonococcal infections:

25 to 50 mg/kg one time only (do not exceed 125 mg).

DOSE ADJUSTMENTS

In adults with both hepatic and renal impairment, dose should not exceed 2 Gm daily. ■ Dose adjustment not required for elderly patients with doses up to 2 Gm/day provided there is no severe renal and hepatic impairment. ■ See Drug/Lab Interactions.

DILUTION

Initially reconstitute each 250 mg of sterile powder with 2.4 mL (500 mg with 4.8 mL, 1 Gm with 9.6 mL, 2 Gm with 19.2 mL) of SWFI, NS, D5W, D10W, D5NS, or D5/½NS for injection (see chart on inside back cover or literature for additional diluents). Each mL will contain 100 mg. A single dose must be further diluted to the desired concentration with the same solution and given as an intermittent infusion. Shake well. Concentrations of 10 mg/mL to 40 mg/mL are recommended for intermittent infusion. Color of solution ranges from light yellow to amber depending on length of storage, concentration, and diluent used. Should not be reconstituted, further diluted, or simultaneously administered with calcium-containing IV solutions. A precipitate can form; see Compatibility. Also available in a premixed frozen Galaxy container, in dual-chamber DUPLEX containers, in ADD-Vantage vials for use with ADD-Vantage infusion containers, and in pharmacy bulk packages. Refer to manufacturer’s prescribing information for specific preparation and storage requirements.

Storage:

See manufacturer's directions. Recommendations for storing vary from CRT (20° to 25° C [68° to 77° F]) to RT (25° C [77° F]) or below and protect from light. Stable at RT for at least 24 hours in stated solutions or selected solutions up to 10 days if refrigerated (see prescribing information). D5NS and D5/½NS should not be refrigerated. Stability and color (light yellow to amber) depend on concentration and diluent. Solutions reconstituted in D5W or NS in concentrations between 10 and 40 mg/mL and then frozen at −20° C in PVC or polyolefin containers remain stable for 26 weeks.

COMPATIBILITY

Manufacturer states, "Do not use diluents containing calcium, such as Ringer's solution or Hartmann's solution, to reconstitute or further dilute ceftriaxone. Particulate formation can result. Ceftriaxone and calcium-containing solutions, including continuous calcium-containing infusions such as parenteral nutrition, should not be mixed or coadministered simultaneously via a **Y-site.**" However, in patients other than neonates, ceftriaxone and calcium-containing solutions may be administered sequentially if the infusion lines are thoroughly flushed between infusions with a **compatible** fluid; see Contraindications and Precautions. Manufacturer lists as **compatible** with metronidazole as an **additive** in NS or D5W if the concentration of metronidazole does not exceed 5 to 7.5 mg/mL with ceftriaxone 10 mg/mL as an admixture. Mixture is stable at RT for 24 hours. Precipitation will occur if refrigerated or if concentration of metronidazole exceeds 8 mg/mL. No studies have been done with Flagyl IV RTU. Manufacturer lists aminoglycosides (e.g., gentamicin), amsacrine, fluconazole, and vancomycin as **incompatible** and states, "May be given sequentially with thorough flushing of the IV line with **compatible** solution between the administrations."

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Intermittent IV:

A single dose over 30 minutes.

Neonates:

Intravenous doses should be given over 60 minutes to reduce the risk of bilirubin encephalopathy.

ACTIONS

A broad-spectrum, third-generation cephalosporin antibiotic. Bactericidal to selected gram-negative, gram-positive, and anaerobic organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Therapeutic concentrations achieved in many body fluids and tissues, including CSF. Highly protein bound. Has a long half-life (range is 5.8 to 8.7 hours), allowing once-a-day dosing for many indications. Peak serum levels achieved by end of infusion. Excreted through urine, bile, and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious lower respiratory tract, urinary tract, skin and skin structure, bone and joint, and intra-abdominal infections. ■ Bacterial septicemia. ■ Meningitis. ■ Most effective against specific organisms (see literature). ■ Perioperative prophylaxis. ■ Given IM for additional indications (e.g., acute bacterial otitis, uncomplicated gonorrhea, and pelvic inflammatory disease).

Unlabeled uses:

Treatment of Lyme disease and numerous other infections. ■ Disseminated gonococcal infections. ■ IM for CDC recommendation for chancroid.

CONTRAINDICATIONS

Known hypersensitivity to ceftriaxone, any of its excipients, or other cephalosporins; see Precautions. ■ Premature neonates up to a postmenstrual age of 41 weeks (gestational age + chronologic age). ■ Hyperbilirubinemic neonates; see Maternal/Child. ■ Coadministration with calcium-containing IV solutions, including parenteral nutrition, in infants up to 28 days of age is contraindicated because of the risk of precipitation of ceftriaxone-calcium salt. Cases of fatal outcomes in which a crystalline material was observed in the lungs and kidneys on autopsy have been reported in neonates receiving ceftriaxone and calcium-containing fluids; see Precautions and Compatibility. ■ Intravenous administration of ceftriaxone solutions containing lidocaine is contraindicated. When lidocaine solution is used as a solvent with ceftriaxone for intramuscular injection, these contraindications do not apply; see IM prescribing information. ■ Solutions containing dextrose may be contraindicated in patients with hypersensitivity to corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported. Obtain history of previous hypersensitivity reactions to penicillins, cephalosporins, other beta-lactam agents, or other allergens. Ceftriaxone should be administered with caution to any patient with such a history. Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies are indicated to determine susceptibility of the causative organism to ceftriaxone. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, ceftriaxone should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 days after all symptoms of infection subside. Usual course of therapy is 4 to 14 days; *S. pyogenes* requires treatment for 10 days. ■ Should not be reconstituted, further diluted, or simultaneously administered with calcium-containing IV solutions. A precipitate can form; see Compatibility. There have been no reports of an interaction between ceftriaxone and oral calcium-containing products or between IM ceftriaxone and oral or IV calcium-containing products. ■ May be associated with an alteration in prothrombin time. Patients at risk include those with impaired vitamin K synthesis or low vitamin K stores (e.g., chronic hepatic disease and malnutrition). Vitamin K administration (10 mg weekly) may be necessary if the prothrombin time is prolonged before or during therapy. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with both impaired renal and hepatic function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ceftriaxone. ■ Immune-mediated hemolytic anemia has been reported in both adults and pediatric patients. Fatalities have occurred. ■ Ceftriaxone-calcium precipitates in the gallbladder have been observed in patients receiving ceftriaxone. These precipitates appear on sonogram and may be misinterpreted as gallstones. Patients may be asymptomatic or may develop symptoms of gallbladder disease. The abnormalities appear to be transient and reversible with the discontinuation of ceftriaxone; see Antidote. ■ Ceftriaxone-calcium precipitates in the urinary tract have been observed in patients receiving ceftriaxone and may be detected as sonographic abnormalities. Patients may be asymptomatic or may develop symptoms of urolithiasis, ureteral obstruction, and postrenal acute renal failure. The condition appears to be reversible with discontinuation of ceftriaxone and institution of appropriate management; see Antidote. ■ Pancreatitis, possibly secondary to biliary obstruction, has been reported.

Monitor:

Watch for early symptoms of a hypersensitivity reaction. ■ Monitor PT/INR and administer vitamin K as indicated; see Precautions. ■ Monitor CBC for development of cephalosporin-induced anemia. ■ Ensure adequate hydration and monitor renal function. ■ See Dose Adjustments and Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels, PT).

Patient Education:

Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy not established. No problems documented. ■ Use caution during breast-feeding. Low concentrations of ceftriaxone are excreted in human milk. ■ Safety and effectiveness of ceftriaxone in neonates, infants, and pediatric patients have been established. Immature renal function of infants and small children will increase blood levels of all cephalosporins. ■ Use is contraindicated in hyperbilirubinemic neonates. Ceftriaxone can displace bilirubin from its binding sites on albumin. Risk of bilirubin encephalopathy exists; see Contraindications and Precautions. ■ Ceftriaxone is also contraindicated in premature neonates up to a postmenstrual age of 41 weeks and in neonates 28 days of age or younger if they require calcium-containing IV solutions; see Contraindications. ■ The probability of ceftriaxone-calcium precipitates in the gallbladder or urinary tract appears to be greatest in pediatric patients.

Elderly:

Response similar to other age-groups; however, greater sensitivity of the elderly cannot be ruled out; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide). ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); may interfere with bactericidal action. ■ Concomitant use with **vitamin K antagonists** (e.g., warfarin) may increase the risk of bleeding. Monitor coagulation parameters frequently, and adjust anticoagulant dose accordingly. ■ May cause false-positive **Coombs' test.** ■ The presence of ceftriaxone may falsely lower estimated blood glucose values obtained with some **blood glucose monitoring systems.** Consult manufacturer's instructions and use alternative testing methods if necessary. ■ May produce false-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ See Compatibility and Side Effects.

SIDE EFFECTS

Full scope of hypersensitivity reactions (e.g., anaphylaxis with fatal outcome, chills, fever, and pruritus) has been reported. Agranulocytosis; allergic pneumonitis; "biliary sludge" or pseudolithiasis; bleeding episodes; burning, discomfort, and pain at injection site; casts in urine; CDAD; colitis; diarrhea; dizziness; dysgeusia; elevated alkaline phosphatase, bilirubin, BUN, creatinine, AST, and ALT; headache; leukopenia; nausea and vomiting; nephrolithiasis; pancreatitis; prolonged PT; renal precipitations; seizures; thrombophlebitis. Other hematologic reactions (e.g., anemia, eosinophilia, hemolytic anemia, leukopenia, lymphopenia, neutropenia, thrombocytopenia, thrombocytosis) may occur. Aplastic anemia, erythema multiforme, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, renal dysfunction, Stevens-Johnson syndrome, toxic epidermal necrolysis, and toxic nephropathy have been reported with cephalosporin-class antibiotics.

Post-Marketing:

Dermatologic reactions (e.g., acute generalized exanthematous pustulosis, allergic dermatitis, exanthema, and isolated cases of Stevens-Johnson syndrome and toxic epidermal necrolysis), genitourinary reactions (e.g., oliguria, postrenal acute renal failure, ureteric obstruction), kernicterus, stomatitis, symptomatic precipitation of ceftriaxone-calcium salt in the gallbladder. Fatal cases of ceftriaxone-calcium precipitates in lungs and kidneys of neonates have been reported; see Contraindications, Precautions, and Maternal/Child.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated (e.g., CDAD, hypersensitivity reactions, seizures, S/S of gallbladder disease, or S/S suggestive of urolithiasis, oliguria, or renal failure). Treat hypersensitivity reactions as indicated and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of ceftriaxone. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Vitamin K may be useful in bleeding episodes, or drug may need to be discontinued. Not removed by hemodialysis.

CEFUROXIME SODIUM

(sef-your-**OX**-eem **SO**-dee-um)
Zinacef
Antibacterial (cephalosporin)
pH 5 to 8.5

USUAL DOSE

Cefuroxime:

Dependent on seriousness of infection. Usual dose is 750 mg to 1.5 Gm every 8 hours for 5 to 10 days. Maximum dose is 3 Gm every 8 hours.

Uncomplicated infections (gonococcal, pneumonia, skin and soft tissue, urinary tract):

750 mg every 8 hours.

PEDIATRIC DOSE

Do not exceed adult dose.

Pediatric patients 3 months of age or older:

50 to 100 mg/kg/day in equally divided doses every 6 to 8 hours (12.5 to 25 mg/kg every 6 hours or 16.7 to 33.3 mg/kg every 8 hours). Higher-end dosing used for more serious infections.

Bone and joint infections:

50 mg/kg every 8 hours. Up to 1.5 Gm/dose has been given.

Bacterial meningitis:

200 to 240 mg/kg/day in equally divided doses every 6 to 8 hours (50 to 60 mg/kg every 6 hours or 66.7 to 80 mg/kg every 8 hours); see Precautions.

NEONATAL DOSE

Neonatal doses are unlabeled; see Precautions and Maternal/Child.

The American Academy of Pediatrics suggests the following doses:

Neonates: 7 days of age or younger regardless of weight:

50 mg/kg every 12 hours.

Neonates from 8 to 28 days of age weighing 2 kg or less:

50 mg/kg every 8 to 12 hours.

Neonates from 8 to 28 days of age weighing more than 2 kg:

50 mg/kg every 8 hours.

DOSE ADJUSTMENTS

Reduced doses or extended intervals may be indicated in the elderly; consider age-related impaired organ function, nutritional status, and concomitant disease or drug therapy.

Adults:

Reduce total daily dose if renal function impaired according to the following chart. ■ See Drug/Lab Interactions.

Cefuroxime Dose Guidelines in Impaired Renal Function in Adults		
Creatinine Clearance (mL/min)	**Dose**	**Frequency**
>20 mL/min	750 mg-1.5 Gm	q 8 hr
10-20 mL/min	750 mg	q 12 hr
<10 mL/min	750 mg	q 24 hr
Hemodialysis patients	An additional dose of 750 mg at end of each dialysis session	

Pediatric patients:

In pediatric patients with impaired renal function, reduce frequency as indicated in the chart for adults.

DILUTION

Reconstitute 750 mg with 8.3 mL SWFI. Reconstitute 1.5 Gm with 16 mL SWFI. Shake well. May be further diluted to 50 or 100 mL with D5W, NS, or other **compatible** infusion solution (see chart on inside back cover or literature) and given as an intermittent infusion, or added to 500 to 1,000 mL and given as a continuous infusion. Also available in dual-chamber DUPLEX containers, ADD-Vantage vials, Twist vials, premixed frozen Galaxy bags, and pharmacy bulk packaging. Refer to manufacturer's prescribing information for specific preparation and storage requirements.

Storage:

In dry state, store between 15° and 30° C (59° to 86° F); protect from light. Reconstituted vials are stable for 24 hours at CRT or 48 hours if refrigerated. Diluted solutions may be stable for up to 7 days if refrigerated.

COMPATIBILITY

May be used concomitantly with aminoglycosides (e.g., amikacin, gentamicin), but these drugs must never be mixed in the same infusion (mutual inactivation). If given concurrently, administer separately and flush the IV line before and after administration. Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion and lists sodium bicarbonate **incompatible** as a diluent.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

See Compatibility. Injection or intermittent infusion may be given through Y-tube or three-way stopcock of infusion set.

IV injection:

A single dose equally distributed over 3 to 5 minutes.

Intermittent IV:

A single dose over 15 to 30 minutes.

Continuous infusion:

500 to 1,000 mL over 6 to 24 hours, depending on total dose and concentration.

ACTIONS

A broad-spectrum, second-generation cephalosporin antibiotic. Bactericidal to selected gram-negative and gram-positive organisms. Effective against many otherwise resistant organisms. Inhibits bacterial cell wall synthesis. Peak serum levels achieved by end of infusion. Widely distributed. 50% bound to serum proteins. Therapeutic concentrations found in pleural fluid, joint fluid, bile, sputum, bone, aqueous humor, and CSF. Half-life is 80 minutes. Excreted in the urine. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of patients with infections caused by susceptible strains of designated organisms in the following diseases: serious lower respiratory tract, urinary tract, bone and joint, skin and skin structure infections, septicemia, and meningitis. ■ Perioperative prophylaxis. ■ Used IM to treat gonorrhea.

CONTRAINDICATIONS

Previous hypersensitivity reaction to cephalosporins; see Precautions. ■ Premixed solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products.

PRECAUTIONS

Hypersensitivity reactions, including fatalities, have been reported and include reports of individuals with a history of penicillin hypersensitivity or sensitivity to multiple allergens experiencing severe reactions when treated with cephalosporins. Check history of previous hypersensitivity reactions to penicillins, cephalosporins, or other allergens.

Actual incidence of cross-allergenicity not established but may be more common with first-generation cephalosporins. ■ Sensitivity studies indicated to determine susceptibility of the causative organism to cefuroxime. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, cefuroxime should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Continue for at least 2 to 3 days after all symptoms of infection subside. ■ Continue treatment of *Streptococcus pyogenes* infections for a minimum of 10 days to decrease the risk of rheumatic fever or glomerulonephritis. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Use caution in patients with impaired renal function, allergies, or a history of GI disease (especially colitis). ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with cefuroxime. ■ May be associated with a fall in prothrombin activity. Patients at risk include those with renal or hepatic impairment, patients with poor nutritional status, patients receiving a protracted course of antimicrobial therapy, and patients previously stabilized on anticoagulant therapy; see Monitor. ■ Mild to moderate hearing loss has been reported in a few pediatric patients treated for meningitis.

Monitor:

Obtain baseline SCr and monitor renal function periodically during therapy. ■ Watch for early symptoms of a hypersensitivity reaction. ■ May cause thrombophlebitis. Use small needles and large veins, and rotate infusion sites. ■ Monitor PT and administer vitamin K as indicated. ■ See Drug/Lab Interactions; additional monitoring may be indicated (e.g., renal function, drug serum levels).

Patient Education:

Report promptly any bleeding or bruising or symptoms of hypersensitivity (e.g., difficulty breathing, hives, itching, rash). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category B: safety for use during pregnancy and breast-feeding not established. No problems documented. ■ Is used in infants under 3 months of age, but safety not established; immature renal function will increase blood levels.

Elderly:

See Dose Adjustments. ■ Response similar to other age-groups; however, greater sensitivity of the elderly cannot be ruled out.

DRUG/LAB INTERACTIONS

Risk of nephrotoxicity may be increased with **aminoglycosides and other nephrotoxic agents** (e.g., loop diuretics such as furosemide). ■ **Probenecid** inhibits excretion. Reduced dose of cefuroxime may be required with concomitant use. ■ May be antagonized by **bacteriostatic antibiotics** (e.g., chloramphenicol, erythromycin, tetracyclines); bactericidal action may be negated. ■ May cause a false-negative reaction in specific **blood glucose** tests (ferricyanide). ■ False-positive reaction for **urine glucose** except with enzyme-based tests (e.g., Clinistix). ■ False-positive **Coombs' test.** ■ See Compatibility and Side Effects.

SIDE EFFECTS

Full scope of hypersensitivity reactions, including anaphylaxis, drug fever, erythema multiforme, interstitial nephritis, positive Coombs' test, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, and urticaria. CDAD; decreased hemoglobin, hematocrit, or platelet functions; diarrhea; elevation of AST, ALT, total bilirubin, alkaline phosphatase, LDH, and BUN/SCr (transient); eosinophilia; fever; leukopenia; local site pain; nausea; oral thrush; seizures (large doses and decreased renal function); transient neutropenia; thrombocytopenia; and thrombophlebitis have occurred. Abdominal pain, agranulocytosis, aplastic anemia, colitis, hemolytic anemia, hemorrhage, hepatic dysfunction (including cholestasis), pancytopenia, prolonged prothrombin time, renal dysfunction, toxic nephropathy, and vaginitis, including vaginal candidiasis, have been reported with cephalosporin-class antibiotics.

Post-Marketing:

Angioedema, cutaneous vasculitis, seizures.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Treat hypersensitivity reactions and resuscitate as necessary. Hemodialysis or peritoneal dialysis may be somewhat useful in overdose.

CEMIPLIMAB-rwlc

(se-**MIP**-li-mab-rwlc)
Libtayo
Antineoplastic
Monoclonal antibody (Anti-PD-1)
pH 6

USUAL DOSE

Pretreatment:

Verify pregnancy status, baseline studies indicated; see Monitor.

Cemiplimab-rwlc:

350 mg administered as an IV infusion over 30 minutes every 3 weeks until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Withhold or discontinue cemiplimab-rwlc to manage adverse reactions as outlined in the following chart. No dose reduction of cemiplimab-rwlc is recommended.

Recommended Dose Modifications for Cemiplimab-rwlc Adverse Reactions		
Adverse Reaction	**Severity**[a]	**Cemiplimab-rwlc Dosage Modifications**
Severe and Fatal Immune-Mediated Adverse Reactions		
Pneumonitis	Grade 2	Withhold[b]
	Grade 3 or 4	Permanently discontinue
Colitis	Grade 2 or 3	Withhold[b]
	Grade 4	Permanently discontinue
Hepatitis	If AST or ALT increases to more than 3 and up to 10 × ULN or if total bilirubin increases up to 3 × ULN	Withhold[b]
	If AST or ALT increases to more than 10 × ULN or total bilirubin increases to more than 3 × ULN	Permanently discontinue
Endocrinopathies	Grade 2, 3, or 4	Withhold if clinically necessary
Other immune-mediated adverse reactions involving a major organ	Grade 3	Withhold[b]
	Grade 4	Permanently discontinue
Recurrent or persistent immune mediated adverse reactions	Recurrent Grade 3 or 4	Permanently discontinue
	Grade 2 or 3 persistent for 12 weeks or longer after last cemiplimab-rwlc dose	
	Requirement for 10 mg per day or greater prednisone or equivalent lasting 12 weeks or longer after last cemiplimab-rwlc dose	
Other Adverse Reactions		
Infusion-related reactions	Grade 1 or 2	Interrupt or slow the rate of the infusion
	Grade 3 or 4	Permanently discontinue

[a] Toxicity graded per National Cancer Institute Common Terminology Criteria for Adverse Events, v4.0 (NCI CTCAE v4).

[b] Resume in patients with complete or partial resolution (Grade 0 or 1) after corticosteroid taper.

DILUTION

Available as a clear to slightly opalescent, colorless to pale-yellow solution in a single-use vial containing 350 mg/7 mL (50 mg/mL). Discard the vial if the solution is cloudy, discolored, or contains extraneous particulate matter other than trace amounts of translucent-to-white particles. Withdraw 7 mL and dilute with NS or D5W to a final concentration between 1 and 20 mg/mL (e.g., mix 350 mg in 100 mL to obtain a final concentration of 3.5 mg/mL). Mix the diluted solution by gentle inversion. ***Do not shake***.

Filters:

Must be administered through an IV line containing a sterile, in-line, or add-on 0.2- to 5-micron filter.

Storage:

Before use, refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake. After preparation, store the prepared infusion at room temperature for no more than 8 hours from the time of preparation to the end of the infusion, or refrigerate for no more than 24 hours from the time of preparation to the end of the infusion. Administration time is included in storage time. If refrigerated, allow the diluted solution to come to room temperature before administration. Do not freeze. Discard partially used vials.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes through an IV line containing a sterile, in-line, or add-on 0.2- to 5-micron filter. Interrupt, slow the rate of infusion, or permanently discontinue based on severity of any infusion-related reaction; see Dose Adjustments and Antidote.

ACTIONS

An antineoplastic agent. Cemiplimab-rwlc is a programmed death receptor-1 (PD-1) blocking antibody; a recombinant human immunoglobulin G4 (IgG4) monoclonal antibody that binds to the PD-1 receptor and blocks its interaction with PD-L1 and PD-L2. Binding of the PD-1 ligands PD-L1 and PD-L2 to the PD-1 receptor found on T-cells inhibits T-cell proliferation and cytokine production. Upregulation of the PD-1 ligands occurs in some tumors, and signaling through this pathway can contribute to inhibition of active T-cell immune surveillance of tumors. Blocking the interaction between PD-1 and the PD-1 ligands releases the PD-1 pathway–mediated inhibition of the immune response, including the antitumor immune response. In syngeneic mouse tumor models, blocking PD-1 activity resulted in decreased tumor growth. Mean elimination half-life is 19 days. Steady-state concentrations were reached after approximately 4 months of treatment when cemiplimab-rwlc was administered at a dose of 350 mg every 3 weeks.

INDICATIONS AND USES

Treatment of patients with metastatic cutaneous squamous cell carcinoma (CSCC) or locally advanced CSCC who are not candidates for curative surgery or curative radiation therapy.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Immune-mediated adverse reactions, which may be severe or fatal, can occur in any organ system or tissue. These reactions usually occur during treatment but can also manifest after discontinuation of therapy. Early identification and management are essential to ensure safe use. ■ Severe immune-mediated pneumonitis, including fatal cases, have occurred with cemiplimab-rwlc treatment. ■ Severe immune-mediated colitis has been reported. ■ Immune-mediated hepatitis, including fatal cases, has occurred with cemiplimab-rwlc treatment. ■ Immune-mediated nephritis has occurred with cemiplimab-rwlc treatment. ■ Immune-mediated skin adverse reactions, including erythema multiforme and pemphigoid, have been reported. Rare cases of Stevens-Johnson syndrome (SJS) and toxic epidermal necrolysis (TEN) have also been reported. ■ Systemic corticosteroids were required in all patients with pneumonitis, colitis, hepatitis, nephritis, and dermatologic adverse reactions during clinical trials. ■ Immune-mediated endocrinopathies, including adrenal insufficiency, hypophysitis (which can result in hypopituitarism), hypothyroidism, hyperthyroidism, and Type 1 diabetes mellitus (with possible diabetic ketoacidosis), have been reported. ■ Numerous other immune-mediated adverse reactions, some with fatal outcome, were reported in fewer than 1% of patients who received cemiplimab-rwlc or other PD-1/PD-L1 blocking antibodies. ■ Severe infusion reactions have been reported. ■ See Dose Adjustments, Monitor, and Antidote for required dose adjustments, indicated criteria and medications for treatment, and criteria for withholding or discontinuation of cemiplimab-rwlc. ■ A protein substance; has a potential for immunogenicity.

Monitor:

Obtain clinical chemistries, including liver and thyroid function tests, at baseline and periodically during treatment. ■ Monitor for S/S of immune-mediated adverse reactions, and institute medical management promptly. Include specialty consultation as appropriate; see Dose Adjustments. ■ For Grade 3 or 4 and certain Grade 2 immune-mediated adverse reactions, administer corticosteroids (1 to 2 mg/kg/day prednisone or equivalent) or other appropriate therapy until improvement to Grade 1 or less followed by a corticosteroid taper over 1 month. Consider administration of other systemic immunosuppressants in patients whose immune-mediated adverse reaction is not controlled with corticosteroids. Institute hormone replacement therapy for endocrinopathies as warranted. ■ Monitor for infusion reactions; see Dose Adjustments and Rate of Administration. ■ Monitor patients for S/S of pneumonitis (e.g., abnormal chest x-ray, chest pain, new or worsening cough, or shortness of breath). ■ Monitor patients for colitis. ■ Monitor for S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of the abdomen, severe nausea or vomiting, abnormal LFTs). ■ Monitor renal function periodically. ■

Monitor for S/S of hypophysitis (e.g., fatigue, headache, low levels of the hormones produced by the pituitary [adrenocorticotropic hormone (ACTH), thyroid-stimulating hormone (TSH), follicle-stimulating hormone (FSH), luteinizing hormone (LH), growth hormone (GH), prolactin]). Administer hormone replacement therapy and corticosteroids as clinically indicated. ■ Monitor for S/S of adrenal insufficiency (e.g., fatigue, nausea, vomiting, hypotension, hyponatremia, hyperkalemia, low cortisol concentrations). Administer corticosteroids as clinically indicated. ■ Monitor for changes in thyroid function. Administer hormone replacement therapy for hypothyroidism. Initiate medical management for control of hyperthyroidism (e.g., methimazole, propylthiouracil). ■ Monitor for hyperglycemia. Administer insulin when clinically indicated. ■ Monitor for development of a rash. ■ Monitor patient for any other clinically significant immune-mediated adverse reactions. Examples of other immune-mediated adverse reactions that have occurred include aplastic anemia, autoimmune neuropathy, duodenitis, encephalitis, gastritis, Guillain-Barré syndrome, hemolytic anemia, hemophagocytic lymphohistiocytosis, histiocytic necrotizing lymphadenitis, immune thrombocytopenic purpura, iritis, meningitis, myasthenic syndrome/myasthenia gravis, myelitis and demyelination, myocarditis, myositis, nerve paresis, pancreatitis, pericarditis, polymyalgia rheumatica, rhabdomyolysis, sarcoidosis, solid organ transplant rejection, systemic inflammatory response syndrome, uveitis, and vasculitides. If uveitis occurs in combination with other immune-mediated adverse reactions, consider a Vogt-Koyanagi-Harada–like syndrome, which may require treatment with systemic steroids to reduce the risk of permanent vison loss. For any suspected immune-mediated adverse reactions, exclude other causes. Based on the severity of the adverse reaction, withhold or discontinue cemiplimab-rwlc, administer high-dose corticosteroids and, if appropriate, initiate hormone replacement therapy.

Patient Education:

Review manufacturer's medication guide. ■ Effective contraception required during treatment with cemiplimab-rwlc and for at least 4 months following the last dose of cemiplimab-rwlc. ■ Promptly report a known or suspected pregnancy. ■ Some side effects may require corticosteroid treatment and interruption or discontinuation of cemiplimab-rwlc. ■ Promptly report any S/S of an infusion-related reaction. ■ Promptly report S/S of pneumonitis (e.g., chest pain, new or worsening cough, or shortness of breath). ■ Promptly report S/S of colitis (e.g., diarrhea, blood or mucus in stools, or severe abdominal pain). ■ Promptly report S/S of hepatitis (e.g., easy bruising or bleeding, jaundice, lethargy, pain on the right side of the abdomen, severe nausea or vomiting). ■ Promptly report S/S of kidney dysfunction (e.g., blood in urine, decreased urine output, loss of appetite, swelling in ankles). ■ Promptly report S/S of hypophysitis, adrenal insufficiency, hypothyroidism, hyperthyroidism, or diabetes mellitus; see Monitor. ■ Promptly report development of a rash. ■ Keeping scheduled appointments for blood work or other laboratory tests is imperative.

Maternal/Child:

Avoid pregnancy. Based on mechanism of action and data from animal studies, cemiplimab-rwlc can cause fetal harm when administered to a pregnant woman. Animal studies have shown that inhibition of the PD-1/PD-L1 pathway can lead to increased risk of immune-mediated rejection of the developing fetus, resulting in fetal death. Human IgG4 is known to cross the placental barrier, and cemiplimab-rwlc is an IgG4 immunoglobin. ■ Discontinue breast-feeding. ■ Safety and effectiveness have not been established for use in pediatric patients.

Elderly:

No overall differences in safety or efficacy were reported between elderly patients and younger patients.

DRUG/LAB INTERACTIONS

No formal pharmacokinetic drug-drug interaction studies conducted with cemiplimab-rwlc.

SIDE EFFECTS

The most common adverse reactions were diarrhea, fatigue, and rash. The most common Grade 3 to 4 adverse reactions were cellulitis, fatigue, hypertension, musculoskeletal pain, pneumonia, sepsis, skin infection, and urinary tract infection. Several immune-mediated reactions have been reported, including colitis, dermatologic adverse reactions/rash, endocrinopathies, hepatitis, nephritis and renal dysfunction, pneumonitis; see Precautions, Monitor, and Antidote. Other reported reactions include constipation, decreased appetite, nausea, and pruritus. Laboratory abnormalities include anemia, hypercalcemia, hypoalbuminemia, hyponatremia, hypophosphatemia, increased AST and INR, and lymphopenia.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Treat side effects aggressively; see Monitor. Follow guidelines for withholding or discontinuing therapy as outlined in Dose Adjustments. Interrupt or slow the rate of administration in patients with mild or moderate infusion reactions. Discontinue in patients with a severe or life-threatening infusion reaction and treat as indicated. Initiate corticosteroid therapy as outlined in Monitor for immune-mediated reactions (e.g., pneumonitis, colitis, hepatitis, renal dysfunction, hypophysitis, adrenal insufficiency, hyperthyroidism or hypothyroidism, rash, and other clinically significant immune-mediated adverse reactions). Hormone replacement may also be indicated; see Monitor. Resuscitate if indicated.

CENTRUROIDES (SCORPION) IMMUNE F(ab’)$_2$ (EQUINE) INJECTION

(**SEN**-troo-roy-deez [**SKOR**-pee-on] i-**MUNE**-fab-too)
Anascorp
Antivenin

USUAL DOSE

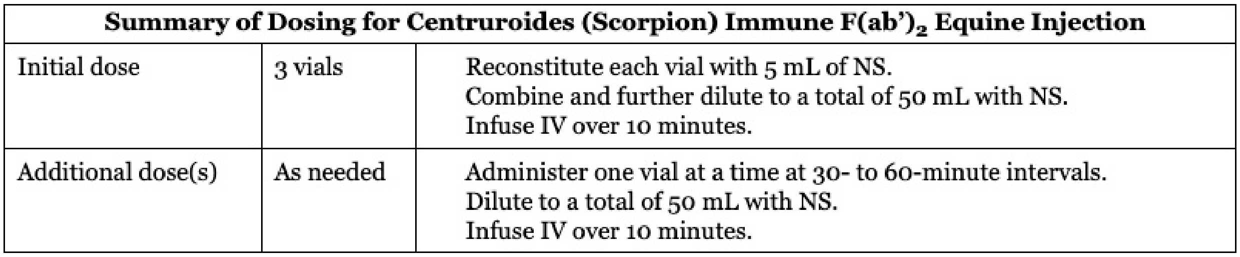
Initiate as soon as possible after scorpion sting in patients who develop clinically important signs of scorpion envenomation (e.g., loss of muscle control, roving or abnormal eye movements, slurred speech, respiratory distress, excessive salivation, frothing at the mouth, and vomiting).

Initial dose:

Entire contents of 3 vials is the recommended initial dose based on clinical experience. Observe during and for up to 1 hour after the initial dose is administered. Desired outcome is resolution of signs of envenomation.

Repeat doses:

If control of symptoms is not accomplished by the initial dose, infuse one vial at a time at intervals of 30 to 60 minutes. Observe as above for resolution of S/S of envenomation. This dose may be repeated until initial control has been established. Maximum number of doses that can be administered safely is unknown.



Summary of Dosing for Centruroides (Scorpion) Immune F(ab')$_2$ Equine Injection		
Initial dose	3 vials	Reconstitute each vial with 5 mL of NS. Combine and further dilute to a total of 50 mL with NS. Infuse IV over 10 minutes.
Additional dose(s)	As needed	Administer one vial at a time at 30- to 60-minute intervals. Dilute to a total of 50 mL with NS. Infuse IV over 10 minutes.

PEDIATRIC DOSE

See Usual Dose. Absolute venom dose following scorpion sting is expected to be the same in pediatric patients and adults; no dose adjustment for age is required. See Maternal/Child.

DILUTION

Initial dose:

Reconstitute each of the 3 vials with 5 mL NS. Mix by continuous gentle swirling. Combine the contents of the reconstituted vials and further dilute to a total volume of 50 mL with NS. For initial and repeat doses, the solution should be clear; do not use if turbidity is present.

Repeat doses:

Reconstitute each single vial with 5 mL NS. Mix by continuous gentle swirling. Further dilute the contents of the reconstituted vial to a total volume of 50 mL with NS.

Filters:

Specific information not available.

Storage:

Store at RT (up to 25° C [77° F]). Temperature excursions are permitted up to 40° C (104° F). Do not freeze. Discard partially used vials.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. Consider administration through a separate line without mixing with other IV fluids or medications due to specific use and potential for anaphylaxis.

RATE OF ADMINISTRATION

A single dose equally distributed over 10 minutes.

ACTIONS

A venom-specific $F(ab')_2$ fragment of equine immune globulin G (IgG) obtained from horse plasma immunized with scorpion venom. Obtained by pepsin digestion of horse plasma to remove the F_c portion of immune globulin, followed by fractionation and purification steps. Binds and neutralizes venom toxins, facilitating redistribution away from target tissues and elimination from the body. Half-life ranges from 102 to 216 hours. Time from the start of injection to resolution of clinical S/S averages 1.42 hours (range 0.2 to 20.5 hours).

INDICATIONS AND USES

Treatment of adult and pediatric patients with clinical signs of scorpion envenomation.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Administer under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities and appropriate emergency drugs to monitor the patient and respond to any medical emergency. ■ Severe hypersensitivity reactions, including anaphylaxis, may occur. Patients with a known allergy to horse protein are particularly at risk for anaphylaxis. Patients who have had a previous equine antivenom/antitoxin may be sensitized to equine proteins and be at risk for severe hypersensitivity reactions. ■ Delayed hypersensitivity reactions (e.g., serum sickness) have been reported. ■ Made from equine (horse) plasma; may carry and transmit infectious agents (e.g., viruses). ■ Contains trace amounts of cresol; may cause localized reactions and generalized myalgias.

Monitor:

Observe closely for S/S of a hypersensitivity reaction (e.g., chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, rigors, urticaria); see Antidote. ■ Monitor closely during infusion and for a minimum of 1 hour to assess if clinically important signs of envenomation have resolved. ■ Follow-up visits are recommended to monitor for S/S of serum sickness (e.g., arthralgia, fever, myalgia, rash).

Patient Education:

Promptly report any S/S of delayed hypersensitivity reactions or serum sickness (e.g., arthralgia, fever, joint pain, lymphadenopathy, malaise, pruritus, rash). May occur up to 14 days following discharge.

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Use caution; safety for use during breast-feeding not established. ■ Safety and effectiveness comparable in pediatric and adult patients. Pediatric patients generally experienced a slightly faster time to resolution (1.28 ± 0.8 hours) compared with adults (1.91 ± 1.4 hours).

Elderly:

Safety and effectiveness comparable to overall patient population.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted. ■ Time to resolution of symptoms was not affected by the use of sedatives.

SIDE EFFECTS

The most common side effects were fever, nausea, pruritus, rash, and vomiting. Hypersensitivity reactions, including anaphylaxis, have occurred. Less common side effects included cough, diarrhea, fatigue, headache, lethargy, myalgia, and rhinorrhea. Other rarely reported side effects included aspiration, ataxia, hypoxia, pneumonia, respiratory distress, serum sickness, and swelling of the eyes.

Post-Marketing:

Chest tightness, palpitations.

ANTIDOTE

Keep the physician informed of all side effects and the extent or progression of envenomation. Discontinue the drug and treat hypersensitivity reactions and/or anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

CETIRIZINE HYDROCHLORIDE

(se-**TIR**-a-zeen)
Quzyttir
Histamine H_1 antagonist
pH 4.5 to 6.5

USUAL DOSE

Adults and adolescents 12 years of age and older:

10 mg as an IV injection over 1 to 2 minutes once every 24 hours.

PEDIATRIC DOSE

Pediatric patients 6 to 11 years of age:

5 mg or 10 mg depending on symptom severity as an IV injection over 1 to 2 minutes once every 24 hours.

Pediatric patients 6 months to 5 years of age:

2.5 mg as an IV injection over 1 to 2 minutes once every 24 hours.

DOSE ADJUSTMENTS

Not recommended in pediatric patients under 6 years of age with impaired renal or hepatic function. ■ No dose adjustment required in other patients with hepatic impairment or in renal impairment, including patients on dialysis; see Monitor.

DILUTION

Available as a ready-to-use, clear, colorless solution in a single-dose vial containing 10 mg/mL.

Filters:

Specific information not available.

Storage:

Store at CRT. Discard any unused portion.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose as an IV push over 1 to 2 minutes.

ACTIONS

A selective histamine-1 (H_1) receptor antagonist. Its principal effects are mediated via selective inhibition of peripheral H_1 receptors. It has negligible anticholinergic and antiserotonergic activity. Activity persists for at least 24 hours. Peak concentrations achieved in 0.03 hours (range 0.03 to 2 hours). Mean plasma protein binding is 93%. Metabolized to a limited extent by oxidative O-dealkylation to a metabolite with negligible antihistaminic activity. Mean elimination half-life is 8.3 hours. Excreted primarily in urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of acute urticaria in adults and pediatric patients 6 months of age and older.

Limitation of use:

Not recommended in pediatric patients under 6 years of age with impaired renal or hepatic function.

CONTRAINDICATIONS

Known hypersensitivity to cetirizine hydrochloride or any of its ingredients, levocetirizine, or hydroxyzine.

PRECAUTIONS

Somnolence/sedation have been reported.

Monitor:

Observe for effectiveness. ■ Monitor for somnolence/sedative effects. ■ Monitor for antihistamine side effects in patients with renal or hepatic impairment.

Patient Education:

May cause somnolence/sedation. Exercise caution when driving a car or operating potentially dangerous machinery. ■ Avoid concurrent use with alcohol or other CNS depressants. May cause additional reduction in alertness and additional impairment of CNS performance.

Maternal/Child:

No adequate and well-controlled studies in pregnant women. No evidence to date of fetal harm in animal studies. ■ Present in breast milk. Consider risk versus benefits. ■ Safety and effectiveness have been established in pediatric patients 6 months to 17 years of age. ■ Safety and effectiveness in pediatric patients under 6 months of age have not been established.

Elderly:

Response similar to that seen in younger adults, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

Formal drug interaction studies are not available. ■ **Alcohol and/or other CNS depressants** may increase somnolence/sedation effects. ■ A small decrease in the clearance of cetirizine may occur with larger **theophylline** doses.

SIDE EFFECTS

The most common adverse reactions (incidence less than 1%) are dysgeusia, dyspepsia, feeling hot, headache, hyperhidrosis, paresthesia, and presyncope.
Somnolence/sedation have also been reported.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be tolerated or treated symptomatically. Not removed by dialysis.

CETUXIMAB BBW

(seh-**TUX**-ih-mab)
Erbitux
Recombinant monoclonal antibody
Antineoplastic
Epidermal growth factor receptor (EGFR) inhibitor
pH 7 to 7.4

USUAL DOSE

Pretreatment:

Verify pregnancy status. Preassessment required to determine appropriate patient selection for patients with colorectal cancer; baseline studies indicated; see Monitor.

Premedication:

To prevent or attenuate severe infusion reactions, premedicate with an H_1 antagonist (e.g., diphenhydramine 50 mg) IV 30 to 60 minutes before the first dose. Premedication for subsequent infusions should be based on clinical judgment and the presence/severity of previous infusion reactions.

Squamous cell carcinoma of the head and neck (SCCHN) in combination with radiation therapy or in combination with platinum-based therapy with 5-FU:

First infusion:

400 mg/M^2 as an initial loading dose 1 week **before the initiation** of a course of radiation therapy or on the day of initiation of platinum-based therapy with 5-FU. Complete cetuximab administration 1 hour before beginning platinum-based therapy with 5-FU.

Subsequent infusions:

250 mg/M^2 once each week for the duration of radiation therapy (6 to 7 weeks) or until disease progression or unacceptable toxicity when administered with platinum-based therapy with 5-FU. Complete infusion 1 hour before radiation therapy or platinum-based therapy with 5-FU.

Squamous cell carcinoma of the head and neck as monotherapy:

First infusion:

400 mg/M^2 as an initial loading dose.

Subsequent infusions:

250 mg/M^2 once each week as a maintenance dose. Continue until disease progression or unacceptable toxicity.

Colorectal cancer in combination with irinotecan, FOLFIRI, or as monotherapy:

Determine epidermal growth factor receptor (EGFR)-expression status and absence of a *Ras* mutation before initiating treatment; see Indications.

First infusion:

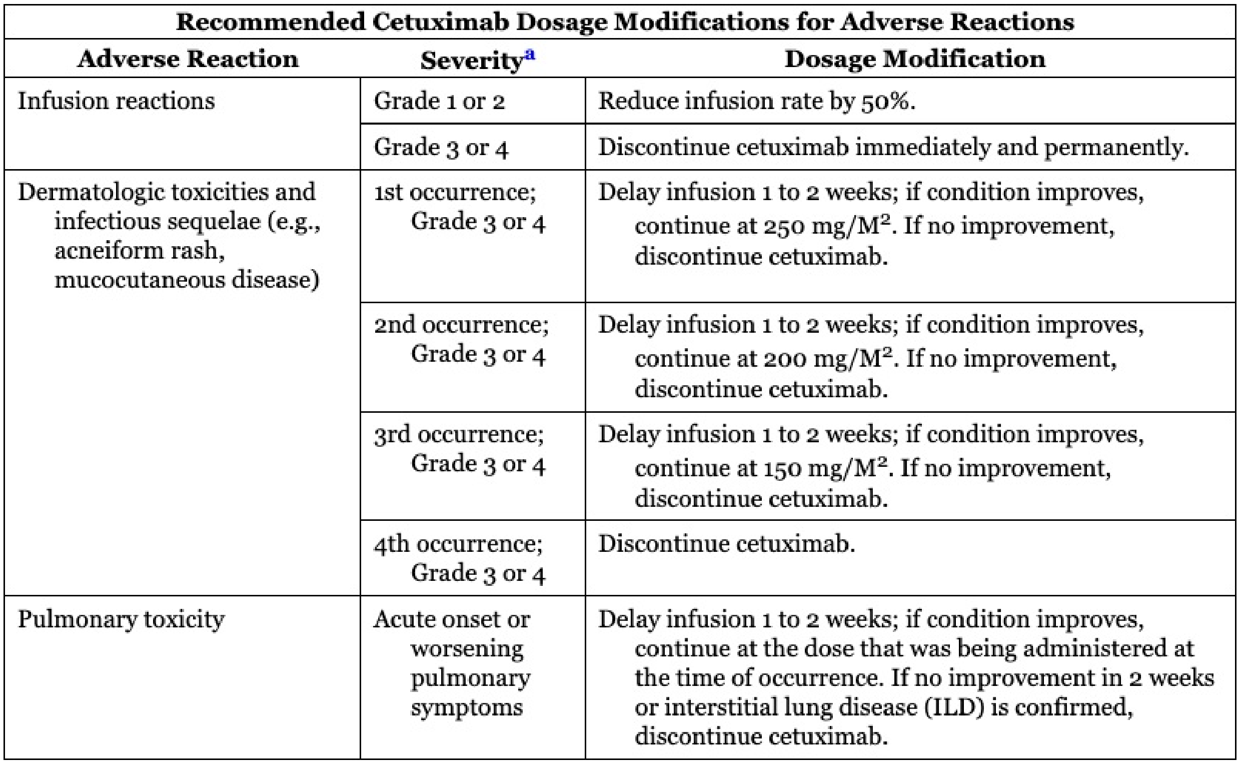
400 mg/M^2 as an initial loading dose. Complete infusion 1 hour before irinotecan or FOLFIRI (irinotecan, 5-FU, leucovorin) when given as combination therapy.

Subsequent infusions:

250 mg/M^2 once each week as a maintenance dose. Complete infusion 1 hour before irinotecan or FOLFIRI when given as combination therapy. Continue until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

No dose adjustment required based on age, gender, race, or hepatic or renal function. ■ No dose adjustment indicated for mild to moderate skin toxicity. ■ Reduce, delay, or discontinue cetuximab to manage adverse reactions as described in the following chart.



Recommended Cetuximab Dosage Modifications for Adverse Reactions

Adverse Reaction	Severity[a]	Dosage Modification
Infusion reactions	Grade 1 or 2	Reduce infusion rate by 50%.
	Grade 3 or 4	Discontinue cetuximab immediately and permanently.
Dermatologic toxicities and infectious sequelae (e.g., acneiform rash, mucocutaneous disease)	1st occurrence; Grade 3 or 4	Delay infusion 1 to 2 weeks; if condition improves, continue at 250 mg/M^2. If no improvement, discontinue cetuximab.
	2nd occurrence; Grade 3 or 4	Delay infusion 1 to 2 weeks; if condition improves, continue at 200 mg/M^2. If no improvement, discontinue cetuximab.
	3rd occurrence; Grade 3 or 4	Delay infusion 1 to 2 weeks; if condition improves, continue at 150 mg/M^2. If no improvement, discontinue cetuximab.
	4th occurrence; Grade 3 or 4	Discontinue cetuximab.
Pulmonary toxicity	Acute onset or worsening pulmonary symptoms	Delay infusion 1 to 2 weeks; if condition improves, continue at the dose that was being administered at the time of occurrence. If no improvement in 2 weeks or interstitial lung disease (ILD) is confirmed, discontinue cetuximab.

[a] National Cancer Institute (NCI) Common Toxicity Criteria (CTC), version 2.0.

DILUTION

Available in 100 mg/50 mL and 200 mg/100 mL single-use vials (2 mg/mL). Multiple vials may be needed for each dose. May pool volume required to provide calculated dose into an empty evacuated container. Solution is clear and may contain small amounts of easily visible white particulates. ***Do not shake or dilute.***

Filters:

Use of a low–protein binding, 0.22-micron in-line filter is required; see Rate of Administration.

Storage:

Refrigerate vials at 2° to 8° C (36° to 46° F). Do not freeze. Preparations in infusion containers are chemically and physically stable for 12 hours if refrigerated or 8 hours at CRT (20° to 25° C [68° to 77° F]). Discard remaining solution in the infusion container after 8 hours at CRT. Discard any unused portion of the vial.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Do not administer as an IV push or bolus. Must be given as an infusion via an infusion pump or a syringe pump. Must be administered through a low–protein binding, 0.22-micron in-line filter.

First infusion:

The initial loading dose should be infused evenly distributed over 2 hours (120 minutes). Do not exceed a rate of 10 mg/min (5 mL/min). In patients who have Grade 1 or 2 infusion reactions, decrease the rate of administration by 50%; see Dose Adjustments.

Subsequent infusions:

Weekly maintenance doses should be infused evenly distributed over 1 hour (60 minutes). Do not exceed a rate of 10 mg/min (5 mL/min). In patients who have Grade 1 or 2 infusion reactions, decrease the rate of administration by 50%; see Dose Adjustments.

ACTIONS

An antineoplastic agent. A human/mouse monoclonal antibody produced by recombinant DNA technology that acts as an epidermal growth factor receptor (EGFR) antagonist. Cetuximab is composed of the Fv regions of a murine anti-EGFR antibody with human IgG1 heavy and kappa light-chain constant regions. Designed to bind to the EGFR found on the surface of both normal cells and tumor cells, resulting in inhibition of cell growth, induction of apoptosis, and decreased matrix metalloproteinase and vascular endothelial growth factor production. Antitumor effects were not observed in tumor cells that did not express the EGFR. With the recommended dose regimen, cetuximab concentrations reached steady-state levels by the third weekly infusion with a mean half-life of 112 hours (range 63 to 230 hours). IgG antibodies may cross the placental barrier and may be secreted in breast milk.

INDICATIONS AND USES

Initial treatment of locally or regionally advanced SCCHN in combination with radiation therapy. ■ First-line treatment of patients with recurrent locoregional disease or metastatic SCCHN in combination with platinum-based therapy with 5-FU. ■ Used as a single agent for the treatment of patients with recurrent or metastatic SCCHN in whom platinum-based chemotherapy has failed. ■ Treatment of K-*Ras* wild type, epidermal growth factor receptor (EGFR)–expressing metastatic colorectal cancer (mCRC) as determined by FDA-approved tests for this use. Used in combination with FOLFIRI (irinotecan, 5-fluorouracil, leucovorin) for first-line treatment. Used in combination with irinotecan (Camptosar) in patients who are refractory to irinotecan-based chemotherapy. Used as a single agent in patients who cannot tolerate irinotecan or in those who have failed treatment with irinotecan (Camptosar)– and oxaliplatin (Eloxatin)–based regimens.

Limitation of use:

Not indicated for treatment of *Ras*-mutant colorectal cancer or when the results of the *Ras* mutation tests are unknown.

CONTRAINDICATIONS

Manufacturer states, “None.” However, a repeat dose is contraindicated in any patient who has a severe infusion reaction. ■ Use with caution in patients with known hypersensitivity to murine proteins, cetuximab, or any of its components.

PRECAUTIONS

Do not administer as an IV push or bolus. Must be given as an infusion via an infusion pump or a syringe pump. ■ Should be administered by or under the direction of the physician specialist in a facility equipped to monitor the patient and respond to any medical emergency. ■ Severe infusion reactions have occurred, and some have been fatal. Most severe reactions occur with the first infusion and have occurred even with the use of prophylactic antihistamines. Risk of anaphylactic reactions may be increased in patients with a history of tick bites, red meat allergy, or in the presence of IgE antibodies directed against galactose-α-1,3-galactose (alpha-gal). ■ Cardiopulmonary arrest and/or sudden death has been reported in patients with SCCHN treated with cetuximab and radiation and in patients with SCCHN treated with cetuximab and a combination of platinum-based therapy with 5-FU. Carefully consider the use of cetuximab in combination with radiation therapy or platinum-based therapy with 5-FU in patients with head and neck cancer who have a history of arrhythmias, coronary artery disease, or congestive heart failure. ■ Pulmonary toxicity, including interstitial lung disease (ILD), has been reported. ■ Severe dermatologic toxicities, including acneiform rash, skin drying and fissuring, and inflammatory and infectious sequelae (e.g., blepharitis [inflammation of the eyelids], cellulitis [diffuse subcutaneous inflammation of connective tissues], cheilitis [inflammation of the lip], conjunctivitis, hypertrichosis, and keratitis/ulcerative keratitis with decreased visual acuity), have occurred and may be dose limiting. Complications involving *S. aureus* sepsis and abscesses requiring incision and drainage have been reported. Life-threatening and fatal bullous mucocutaneous disease with blisters, erosions, and skin sloughing has been observed. ■ In a controlled study, the addition of cetuximab to radiation and cisplatin led to an increased incidence of serious toxicity and death without any improvement in progression-free survival. Cetuximab is not indicated for the treatment of SCCHN in combination with radiation and cisplatin. ■ May cause electrolyte abnormalities. ■ A protein substance, it has the potential for producing immunogenicity. However, there does not appear to be a relationship between the appearance of antibodies to cetuximab and the safety or antitumor activity of the molecule. ■ See Monitor and Antidote.

Monitor:

Determine EGFR-expression status and the absence of a *Ras* mutation in patients with metastatic colorectal cancer (mCRC) using FDA-approved tests before initiating treatment. See prescribing information for access to FDA-approved tests. Use of cetuximab in patients with *Ras* mutant mCRC resulted in no clinical benefit and increased tumor progression, toxicity, and mortality. Expression of EGFR has been detected in nearly all patients with SCCHN, so determination of EGFR-expression status is not required in this patient population. ■ Monitor VS frequently. ■ Observe patient closely during every infusion and for at least 1 hour after each infusion. Monitor longer to confirm resolution of the event in patients requiring treatment for infusion reactions. Infusion reactions can occur during or several hours after completion of the infusion, even in patients who are premedicated with diphenhydramine and/or who have not had infusion reactions with previous doses; see Precautions. S/S of severe reactions may include hypotension, rapid onset of airway obstruction (e.g., bronchospasm, hoarseness, stridor), loss of consciousness, MI, shock, and/or cardiac arrest. ■ Monitor serum electrolytes, including magnesium, calcium, and potassium, weekly during therapy and for 8 weeks following completion. Electrolyte loss may occur from days to months after initiating cetuximab. Oral or parenteral electrolyte replacement may be indicated. ■ Monitor for S/S of dermatologic toxicity such as acneiform rash (e.g., multiple follicular-pustular–appearing lesions on the face, upper chest, back, and extremities), skin drying, and fissuring. Dose adjustments or termination of therapy may be indicated; see Dose Adjustments and Precautions. The first onset of acneiform rash may occur within the first 2 weeks, may subside when treatment is discontinued, or may persist for longer periods. The rash lasted more than 28 days after stopping cetuximab in most patients. Inflammatory or infectious sequelae (e.g., blepharitis, cellulitis, cheilitis) may develop and should be treated promptly. ■ Monitor for S/S of interstitial lung disease (e.g., dyspnea on exertion, nonproductive cough, inspiratory crackles on chest examination). Acute onset or worsening symptoms may require interruption or discontinuation of cetuximab therapy. ■ See Dose Adjustments, Rate of Administration, Precautions, and Antidote.

Patient Education:

Verify pregnancy status in females of reproductive potential before initiating therapy. Avoid pregnancy; use of effective birth control recommended for females during therapy and for 2 months after the last dose. See Maternal/Child. Women should report a suspected pregnancy immediately. ■ Review potential side effects before therapy. ■ Report any unusual or unexpected symptoms or side effects promptly, including infusion-related reactions (e.g., dyspnea, feeling of faintness, hives, wheezing), respiratory reactions (e.g., cough, shortness of breath), or dermatologic toxicities. ■ Review medical history with provider before initiating therapy. ■ Sunlight can worsen the skin reactions that may occur. Limit exposure to the sun (use sunscreen, wear hat and protective clothing) while receiving and for 2 months following the last dose of cetuximab. ■ See Appendix D, p. 1311.

Maternal/Child:

Can cause fetal harm when administered to a pregnant woman. ■ Discontinue breast-feeding during treatment with cetuximab and for 60 days following the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Safety and effectiveness similar to younger adults in CRC trials. SCCHN studies did not include sufficient numbers of patients over age 65 years to determine any differences in efficacy or toxicity.

DRUG/LAB INTERACTIONS

No drug interaction studies have been completed. ■ No pharmacokinetic interaction was observed between cetuximab and irinotecan, cetuximab and cisplatin, and cetuximab and carboplatin. ■ Increased incidence of death and serious toxicity have been observed when **cetuximab, cisplatin, and radiation therapy** have been used concomitantly.

SIDE EFFECTS

The most common side effects are cutaneous adverse reactions (e.g., nail changes, pruritus, rash), diarrhea, headache, and infection. The most serious side effects are cardiopulmonary arrest, dermatologic toxicity, infusion reactions, and interstitial lung disease.

SCCHN:

Anorexia; elevated ALT, AST, and alkaline phosphatase; mucositis/stomatitis/pharyngitis; and radiation dermatitis/toxicities.

Colorectal cancer:

Anxiety, arthralgia, confusion, constipation, cough, depression, dyspnea, fatigue, insomnia, malaise, mouth dryness, neuropathy, neutropenia, pain, stomatitis, and taste disturbance.

All diagnoses:

Acneiform rash, asthenia, chills, conjunctivitis, dehydration, dyspepsia, electrolyte abnormalities (e.g., hypocalcemia, hypokalemia, hypomagnesemia), fever, nausea and vomiting, and weight loss.

Post-Marketing:

Aseptic meningitis, Stevens-Johnson syndrome, toxic epidermal necrolysis, life-threatening and fatal bullous mucocutaneous disease.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Hypersensitivity or infusion-related side effects may resolve with reduction in the rate of infusion by 50% and by continued use of premedication with diphenhydramine. Discontinue cetuximab immediately for severe infusion reactions requiring medical intervention and/or hospitalization; ***do not rechallenge.*** Treat hypersensitivity or infusion reactions as indicated; may require use of epinephrine, corticosteroids, diphenhydramine, bronchodilators (e.g., albuterol, aminophylline), IV saline, oxygen, and/or acetaminophen. Dermatologic toxicities may be dose limiting (see Dose Adjustments) or may be treated with topical and/or oral antibiotics as appropriate. Use of topical corticosteroids is not recommended. Interrupt cetuximab for acute onset or worsening of pulmonary symptoms. Treat as indicated; permanently discontinue cetuximab for confirmed interstitial lung disease. Replace electrolytes as indicated. Resuscitate if indicated.

CHLORAMPHENICOL SODIUM SUCCINATE BBW

(klor-am-**FEN**-ih-kohl **SO**-dee-um **SUK**-suh-nayt)
Chloromycetin
Antibacterial
pH 6.4 to 7

USUAL DOSE

Pretreatment:

For all age levels, determine baseline blood studies before administration. See Monitor and Precautions.

Avoid repeated courses of this drug if at all possible. Treatment should not be continued longer than the time required to produce a cure with little or no risk of relapse of disease.

Adults and pediatric patients with mature metabolic processes (e.g., normal kidney and liver function):

12.5 mg/kg every 6 hours. In exceptional cases, infections due to moderately resistant organisms may require up to 25 mg/kg every 6 hours. Severe infections (e.g., bacteremia or meningitis), especially when adequate cerebrospinal fluid concentrations are desired, may require up to 25 mg/kg every 6 hours. These increased doses must be reduced to 12.5 mg/kg every 6 hours as soon as possible. Maximum dose is 4 Gm/24 hr for all ages.

Change to oral form as soon as practical.

NEONATAL DOSE

When kidney or liver function is immature in infants (or seriously impaired in adults), high concentrations of chloromycetin are found and tend to increase with succeeding doses. See Maternal/Child.

Infants under 2 weeks of age or older infants with immature metabolic processes (e.g., premature infants):

6.25 mg/kg every 6 hours. Increased doses demanded by severe infections should be given only to maintain the blood concentration within a therapeutically effective range. Close monitoring of blood concentrations by microtechniques is recommended (information available from manufacturer).

Infants 2 weeks of age or older with mature metabolic processes:

12.5 mg/kg every 6 hours may ordinarily be administered. See comments under Usual Dose.

Another source suggests a ***loading dose*** followed by ***maintenance doses*** based on age and weight.

Loading dose:

20 mg/kg.

Maintenance dose:

Administer the first maintenance dose 12 hours after the loading dose. ***7 days of age or younger and over 7 days of age if weight is 2 kg or less:*** 25 mg/kg of body weight once daily.

Over 7 days of age and over 2 kg:

25 mg/kg every 12 hours.

DOSE ADJUSTMENTS

Reduce dose and/or initiate oral therapy as soon as feasible. ■ Reduce dose and/or extend intervals in infants and children with immature metabolic processes. See specific dose recommendations. Close monitoring of blood concentrations by microtechniques is recommended. ■ In patients with immature or impaired hepatic or renal function, dose reduction may be required. ■ Dosing should be cautious in the elderly. Consider decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 1 Gm should be reconstituted with 10 mL of SWFI or D5W to prepare a 10% solution (100 mg/mL). May be further diluted in 50 to 100 mL of D5W for intermittent infusion. Give through Y-tube, three-way stopcock, or additive infusion set.

Storage:

Store at CRT. Administer within 24 hours of preparation.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

1 Gm or fraction thereof over a minimum of 1 minute.

Intermittent infusion:

A single dose over 10 to 30 minutes.

ACTIONS

Effective against a wide range of gram-positive and gram-negative bacteria. Primarily bacteriostatic. May be bactericidal at high concentrations or against highly susceptible organisms. Acts by inhibiting protein synthesis. Well distributed in therapeutic doses throughout the body, especially in the liver and kidneys. Lowest concentrations are found in the brain and spinal fluid; however, chloramphenicol enters cerebrospinal fluid even in the absence of meningeal inflammation, appearing in concentrations about half of those found in the blood. Partially metabolized. Excreted in urine, bile, and feces. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Only in serious infections in which potentially less dangerous drugs are ineffective or contraindicated; acute *Salmonella typhi* infections, meningeal infections (e.g., *Haemophilus influenzae*), bacteremia, rickettsia, lymphogranuloma psittacosis, and other serious gram-negative infections. ■ Cystic fibrosis regimens.

CONTRAINDICATIONS

Known chloramphenicol sensitivity. Must not be used in the treatment of trivial infections.

PRECAUTIONS

Serious blood dyscrasias (e.g., aplastic anemia, hypoplastic anemia, thrombocytopenia, and granulocytopenia) resulting in irreversible bone marrow suppression and death are known to occur. Aplastic anemia resulting in leukemia has been reported. Blood dyscrasias have occurred after both short-term and longer-term therapy. Do not use if potentially less dangerous agents would be effective. ■ Administration in a hospital with facilities for monitoring the patient and responding to any medical emergency is preferred. ■ Sensitivity studies mandatory to determine susceptibility of the causative organism not only to chloramphenicol but also to other less dangerous drugs. ■

Superinfection caused by overgrowth of nonsusceptible organisms, including fungi, is possible. Treatment should not be continued longer than required to produce a cure with little or no risk of relapse of the disease. ■ For IV use only. ■ A reversible type of bone marrow suppression characterized by vacuolization of the erythroid cells, reduction of reticulocytes, and leukopenia is dose related and usually responds to withdrawal of chloramphenicol. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with chloramphenicol. ■ Use caution in patients with impaired hepatic and/or renal function.

Monitor:

Obtain blood studies (CBC) before initiating therapy and approximately every 2 days during therapy; discontinue drug if blood studies show any indication of anemia, leukopenia, reticulocytopenia, thrombocytopenia, or any blood study findings attributable to chloramphenicol. ■ Monitor chloramphenicol serum levels at least weekly, and more often if indicated (e.g., impaired liver or kidney function, immature metabolic processes, suspicion of beginning blood dyscrasias). ■ Therapeutic levels range between 15 and 25 mcg/mL for meningitis; 10 and 20 mcg/mL for other infections. Trough levels should range between 5 and 15 mcg/mL for meningitis; 5 and 10 mcg/mL for other infections. ■ Monitor hepatic and renal function as indicated; see Dose Adjustments. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report fever, sore throat, tiredness, unusual bleeding, or bruising. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category C: no studies documented. Use during pregnancy with extreme caution; may have toxic effects on fetus. ■ Discontinue breast-feeding. ■ Blood concentration in all premature and full-term neonates under 2 weeks of age differs from that of other neonates. Use caution, lower doses, and/or extended intervals in premature infants and newborns. May cause gray syndrome (e.g., abdominal distension with or without emesis, progressive pallid cyanosis, vasomotor collapse, irregular respiration, death within a few hours of onset of symptoms); monitor serum levels; see Precautions/Monitor.

Elderly:

See Dose Adjustments. ■ Response similar to that seen in younger patients. ■ Monitor renal function.

DRUG/LAB INTERACTIONS

May cause irreversible bone marrow suppression. Avoid concurrent therapy with **drugs that cause blood dyscrasias** (e.g., penicillins, hydantoins [phenytoin]), **other bone marrow suppressants** (e.g., cytotoxic drugs, radiation therapy). ■ Increases serum levels of **oral antidiabetics** (e.g., chlorpropamide) and increases hypoglycemic effects;

dose reduction may be required. ■ May be synergistic with or antagonize effects of **aminoglycosides, cephalosporins, and penicillins.** (Is used with ampicillin in pediatric patients.) ■ Chloramphenicol can inhibit specific P_{450} enzymes; reduced metabolism and increased serum levels may occur in agents also metabolized by that route (e.g., **chlorpropamide** [Diabinese], **phenobarbital, phenytoin, tolbutamide, warfarin**). ■ Concurrent use with **hydantoins** (e.g., phenytoin) may decrease or increase the effectiveness of chloramphenicol. Hydantoin levels may be increased, resulting in toxicity. ■ Concurrent use with **phenobarbital** may decrease chloramphenicol serum levels and increase phenobarbital serum levels, resulting in phenobarbital toxicity. Monitor serum levels of both drugs if concurrent use is indicated. ■ Concurrent administration with **anticoagulants** (e.g., heparin, warfarin) may prolong PT. ■ May increase **serum iron** levels. ■ May delay response to **antianemia drugs** (e.g., iron preparations, vitamin B_{12}, folic acid). Avoid concurrent use in patients with anemia if possible. ■ **Rifampin** increases chloramphenicol metabolism and decreases its effects.

SIDE EFFECTS

Blood dyscrasias (e.g., aplastic anemia, hypoplastic anemia, granulocytopenia, thrombocytopenia) may result in irreversible bone marrow suppression and death. CDAD, confusion, depression, diarrhea, fever, gray syndrome of newborns and infants, headache, hypersensitivity reactions (e.g., angioedema, anaphylaxis, fever, rashes, urticaria), leukemia, nausea, optic and peripheral neuritis, paroxysmal nocturnal hemoglobinuria, pseudomembranous colitis, rashes, stomatitis, vomiting, and many others. ***May be fatal.***

ANTIDOTE

Notify the physician immediately of any adverse symptoms. Discontinue the drug upon appearance of anemia, leukopenia, reticulocytopenia, thrombocytopenia, or any other blood study findings attributable to chloramphenicol. Discontinue the drug for symptoms of optic and peripheral neuritis. Monitoring of plasma levels is imperative in all patients and especially in neonates. Treat hypersensitivity reactions as indicated. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Resuscitate as necessary.

CHLOROTHIAZIDE SODIUM

(klor-oh-**THIGH**-ah-zyd **SO**-dee-um)
Diuril
Diuretic (thiazide)
Antidiuretic (diabetes insipidus)
pH 9.2 to 10

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

IV and oral doses are therapeutically equivalent. Oral dose can replace an IV dose at any time. 0.5 to 1 Gm once or twice daily. Individualize based on patient response. Use of the smallest dose necessary to achieve desired response is indicated. Some patients respond to intermittent therapy (e.g., every other day or 3 to 5 days out of a week). Intermittent therapy may decrease the incidence of excessive response and the resulting undesirable electrolyte imbalance. Another source suggests the following:

Diuretic:

250 mg every 6 to 12 hours. Up to 2 Gm/24 hr may be indicated.

PEDIATRIC DOSE

Safety and effectiveness in pediatric patients not established; all pediatric doses are **unlabeled;** experience has been limited; see Maternal/Child.

Under 6 months of age (unlabeled):

Begin with 1 to 4 mg/kg every 12 hours. May increase to 10 to 20 mg/kg every 12 hours if needed.

6 months of age or older (unlabeled):

Begin with 2 mg/kg every 12 hours or 4 mg/kg every 24 hours. May increase to 10 mg/kg every 12 hours if needed.

DOSE ADJUSTMENTS

See Drug/Lab Interactions. ■ If progressive renal impairment occurs, consider withholding or discontinuing diuretic therapy. ■ Caution and lower-end dosing suggested in the elderly. Consider potential for age-related impaired organ function and concomitant disease or drug therapy.

DILUTION

Each 0.5 Gm must be reconstituted with at least 18 mL of SW (yields 28 mg/mL). Never use less than 18 mL of SW. Prepare immediately before use. May be given as an IV injection or may be further diluted in dextrose or NS solutions and given as an infusion.

Storage:

Store in powder form at CRT. Contains no preservatives; use reconstituted solution immediately and discard unused portion.

COMPATIBILITY

Manufacturer lists as **incompatible** with whole blood or its derivatives.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

0.5 Gm or fraction thereof as a slow IV injection (e.g., over 2 to 3 minutes) or as an infusion (rate dependent on volume of diluent and patient condition).

ACTIONS

A diuretic and antihypertensive agent. It affects the distal renal tubular mechanism of electrolyte reabsorption. Excretion of sodium and chloride occurs in approximately equal amounts. There is some loss of potassium and bicarbonate. The specific mechanism of its antihypertensive effect is not known; however, it does not affect normal blood pressure. Effectiveness is noted within 15 to 30 minutes. Half-life is approximately 1 to 2 hours; duration of action is 6 to 12 hours. Not metabolized but rapidly excreted unchanged in the urine. Crosses the placental barrier but not the blood-brain barrier. Secreted in breast milk.

INDICATIONS AND USES

Adjunctive therapy in edema associated with congestive heart failure, hepatic cirrhosis, and corticosteroid and estrogen therapy. ■ May be useful in edema due to various forms of renal dysfunction (e.g., nephrotic syndrome, acute glomerulonephritis, chronic renal failure). ■ Edema of pregnancy when edema results from the above conditions (e.g., pathologic causes). ■ Used rarely during a normal pregnancy (in the absence of cardiovascular disease) for edema that causes extreme discomfort not relieved by rest. ■ Adjunctive therapy in the treatment of hypertension.

CONTRAINDICATIONS

Anuria. ■ Hypersensitivity to chlorothiazide, any of its components, or other sulfonamide-derived drugs.

PRECAUTIONS

IV use indicated in patients unable to take oral medication or in emergency situations. For IV use only; do not use IM or SC. ■ Use with caution in severe renal disease; thiazides may precipitate azotemia. ■ Use with caution in patients with impaired renal function; cumulative effects may develop. ■ Use with caution in patients with impaired hepatic function or progressive liver disease; minor alterations of fluid and electrolyte balance may precipitate hepatic coma. ■ Sensitivity reactions may occur in patients with or without a history of allergy or bronchial asthma. ■ Exacerbation and/or activation of systemic lupus erythematosus has been reported. ■ May increase glucose levels, uric acid levels, total cholesterol, HDL, triglycerides, and urine output of magnesium. ■ May decrease calcium excretion. Marked hypercalcemia may indicate hidden hyperparathyroidism; discontinue thiazides before testing for parathyroid function. ■ Antihypertensive effects may be increased in postsympathectomy patients. ■ See Monitor and Drug/Lab Interactions.

Monitor:

Determine absolute patency of vein. Avoid extravasation. ■ Obtain baseline and perform repeat checks routinely of electrolyte panel, CO_2, BUN, uric acid, and glucose. ■ May precipitate excessive diuresis with water and electrolyte depletion. Monitor for S/S of fluid or electrolyte imbalance (e.g., confusion, drowsiness, dryness of mouth, hypochloremic alkalosis, hypokalemia, hyponatremia, hypotension, lethargy, muscle fatigue, muscle pain or cramps, nausea and vomiting, oliguria, restlessness, seizures, tachycardia, thirst, weakness) and replace electrolytes as necessary. Monitor serum and urine electrolytes more closely in patients who are vomiting or receiving parenteral fluids. Monitor VS closely. ■ Monitor closely for hypokalemia (especially during brisk diuresis) in patients with severe cirrhosis or during prolonged treatment. May cause cardiac arrhythmias and/or increase the potential for toxic effects of digoxin. Potassium supplements or the use of potassium-sparing diuretics may be indicated. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Take only prescribed medications. ■ Promptly report dizziness, diarrhea, muscle weakness or cramps, nausea, or vomiting. ■ May cause hypokalemia and require a potassium supplement.

Maternal/Child:

Category C: use only if clearly needed. Crosses the placental barrier; has been found in cord blood and may harm the fetus. ■ Discontinue breast-feeding. ■ Use in infants and pediatric patients has been limited and is not generally recommended; see Pediatric Dose.

Elderly:

Differences in response compared to younger adults not identified. ■ Dose selection should be cautious; see Dose Adjustments. May have increased sensitivity to hypotensive and electrolyte effects. Monitoring of renal function suggested.

DRUG/LAB INTERACTIONS

Do not give simultaneously with **whole blood or its derivatives.** ■ Has antihypertensive actions. May have an additive effect used concurrently with **other antihypertensive agents**; reduced doses of both agents may be indicated. ■ Potential for orthostatic hypotension is increased with concurrent use of **alcohol, barbiturates, or narcotics.** ■ May cause hyperglycemia. Monitor **blood glucose levels** and adjust doses of insulin and oral antidiabetic agents as indicated. ■ Electrolyte depletion (especially hypokalemia) may increase with concurrent administration of **other drugs that cause potassium loss,** such as amphotericin B or corticosteroids. ■ May have a decreased response to **pressor amines** (e.g., norepinephrine); monitor carefully. ■ Concurrent use with **lithium** not recommended; renal excretion of lithium is decreased and potential for lithium toxicity is increased. ■ **NSAIDs** may decrease the effects of diuretics; monitor carefully. ■ Raises blood uric acid; dose adjustment of **antigout agents** (e.g., allopurinol, colchicine) may be indicated. ■ Synergistic effects with **loop diuretics** (e.g., furosemide, torsemide) may cause profound diuresis and serious electrolyte abnormalities. ■ Hypokalemia and hypomagnesemia may cause **digoxin-induced arrhythmias;** monitor potassium levels. ■ Hypersensitivity reactions to **allopurinol** may be increased. ■ May prolong **antineoplastic** (e.g., methotrexate) induced leukopenia. ■ **May cause hypercalcemia** through decreased calcium excretion or increased bone release or by enhancing action of vitamin D. ■ May decrease effects of **anticoagulants.** ■ Discontinue thiazides before **testing for parathyroid function;** see Precautions.

SIDE EFFECTS

Agranulocytosis, alopecia, anorexia, aplastic anemia, blurred vision (transient), constipation, cramping, diarrhea, dizziness, electrolyte imbalance, erythema multiforme (including Stevens-Johnson syndrome, exfoliative dermatitis, and toxic epidermal necrolysis), GI upset, glycosuria, headache, hematuria, hemolytic anemia, hyperglycemia, hypersensitivity reactions, hypotension, jaundice, leukopenia, muscle spasm, nausea and vomiting, orthostatic hypotension, pancreatitis, paresthesias, renal dysfunction, renal failure, restlessness, sialadenitis (inflammation of a salivary gland), thrombocytopenia, vertigo, weakness, yellow vision.

Overdose:

Most common S/S are those caused by electrolyte depletion (e.g., hypokalemia, hyponatremia, hypochloremic alkalosis) and dehydration resulting from excessive diuresis. Cardiac arrhythmias may occur if digoxin is used concurrently.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Reduce chlorothiazide dose or discontinue if side effects are moderate or severe. Treatment of moderate to severe side effects is symptomatic and aggressive. If progressive renal impairment or S/S of hepatic coma occur, consider withholding or discontinuing diuretic therapy. Treatment of overdose is symptomatic and supportive. Correct dehydration, electrolyte imbalance, hepatic coma, and hypotension. Maintain an adequate airway and use oxygen or artificial ventilation for respiratory distress as indicated. Amount of chlorothiazide removed by hemodialysis has not been established. Resuscitate as necessary.

CHLORPROMAZINE HYDROCHLORIDE BBW

(klor-**PROH**-mah-zeen hy-droh-**KLOR**-eyed)
Thorazine
Phenothiazine
Antipsychotic
Antiemetic
pH 3 to 5

USUAL DOSE

Use of the IV route is reserved for the treatment of acute nausea and vomiting in surgery, intractable hiccups, and tetanus.

Acute nausea and vomiting in surgery:

2 mg. May repeat at 2-minute intervals as indicated. Do not exceed 25 mg. Usually given as an infusion.

Intractable hiccups:

25 to 50 mg diluted in 500 to 1,000 mL of NS. Given as a slow IV infusion with patient flat in bed. Monitor BP closely.

Tetanus:

25 to 50 mg as an infusion of at least 1 mg/mL. Individualize dose to patient response and tolerance. Repeat every 6 to 8 hours. Usually given in conjunction with barbiturates.

PEDIATRIC DOSE

See Maternal/Child. IV route rarely used for pediatric patients. Not recommended for use in infants under 6 months of age.

Acute nausea and vomiting in surgery, pediatric patients 6 months of age or older:

1 mg. May repeat at 2-minute intervals as indicated. Monitor for hypotension. Another source suggests 2.5 to 4 mg/kg/24 hr in equally divided doses every 6 to 8 hours (0.625 to 1 mg/kg every 6 hours or 0.83 to 1.33 mg/kg every 8 hours). Usual IV/IM dose does not exceed 2.5 to 4 mg/kg/24 hr or 40 mg/24 hr (whichever is less) in pediatric patients 6 months to 5 years of age or up to 50 lb, and 75 mg/24 hr in pediatric patients 5 to 12 years of age.

Tetanus:

0.55 mg/kg of body weight (0.25 mg/lb) every 6 to 8 hours. Do not exceed 40 mg/24 hr for up to 23 kg (50 lb) and 75 mg/24 hr for up to 50 kg (50 to 100 lb), except in severe cases.

DOSE ADJUSTMENTS

Adjust dose to the individual and severity of condition. Reduce dose of any medication potentiated by phenothiazines by one-fourth to one-half. See Drug/Lab Interactions. ■ Reduce dose by one-fourth to one-half in the elderly, debilitated patients, or emaciated patients, and increase very gradually by response.

DILUTION

Each 25 mg (1 mL) must be diluted with 24 mL of NS for injection. 1 mL will equal 1 mg. May be further diluted in 500 to 1,000 mL of NS and given as an infusion. Handle carefully; may cause contact dermatitis. Sensitive to light. Slightly yellow color does not alter potency. Discard if markedly discolored.

Storage:

Store at CRT. Protect from light and freezing.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Titrate to symptoms and vital signs. See Precautions.

IV injection:

Each 1 mg or fraction thereof over 1 minute.

Infusion:

Given very slowly. Do not exceed 1 mg/min.

Pediatric rate:

Do not exceed 1 mg or fraction thereof over 2 minutes.

ACTIONS

A phenothiazine derivative with effects on the central, autonomic, and peripheral nervous systems. A psychotropic agent. Decreases anxiety and tension, relaxes muscles, produces sedation, and tranquilizes. Has an antiemetic effect and potentiates CNS depressants. Has strong antiadrenergic and anticholinergic activity. Also possesses slight antihistaminic and antiserotonin activity. Onset of action is prompt and of short duration in small IV doses. Extensively metabolized in liver and kidney and excreted primarily in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

The IV route is used only for the treatment of acute nausea and vomiting in surgery, the treatment of intractable hiccups, and as an adjunct in the treatment of tetanus. ■ Used IM or PO for the treatment of schizophrenia and the management of psychotic disorders. ■ Also indicated IM, PO, or rectally to relieve restlessness and apprehension before surgery, to manage acute intermittent porphyria, to control manic episodes in manic-depressive illness, and to treat severe behavioral problems in pediatric patients.

Unlabeled uses:

Treatment of phencyclidine (PCP) psychosis. ■ Treatment of migraine headaches (IV or IM). ■ To reduce choreiform movements of Huntington’s disease.

CONTRAINDICATIONS

Hypersensitivity to phenothiazines, comatose or severely depressed states, or the presence of large amounts of CNS depressants (e.g., alcohol, barbiturates, narcotics).

PRECAUTIONS

Not approved for dementia-related psychosis; mortality risk in elderly dementia patients taking conventional or atypical antipsychotics is increased; most deaths are due to cardiovascular or infectious events. ■ Use of the IV route is reserved for the treatment of acute nausea and vomiting in surgery, intractable hiccups, and tetanus. IM injection preferred. ■ Use caution in patients with bone marrow suppression; glaucoma; cardiovascular, liver, renal, and chronic respiratory diseases; and acute respiratory diseases of pediatric patients. ■ Re-exposure of patients who have experienced jaundice, skin reactions, or blood dyscrasias with a phenothiazine is not recommended. Cross-sensitivity may occur. ■ May produce ECG changes (e.g., prolonged QT interval, changes in T waves). ■ Use with caution in patients with a history of seizure disorders; may lower seizure threshold. ■ Extrapyramidal symptoms caused by chlorpromazine may be confused with CNS signs of an undiagnosed disease (e.g., Reye's syndrome or encephalopathy). ■ May mask diagnosis of brain tumor, drug intoxication, and intestinal obstruction. ■ Tardive dyskinesia (potentially irreversible involuntary dyskinetic movements) may develop. Use smallest doses and shortest duration of therapy to minimize risk. ■ Neuroleptic malignant syndrome (NMS) characterized by hyperpyrexia, muscle rigidity, altered mental status, and autonomic instability has been reported; see Antidote. ■ May cause paradoxical excitation in pediatric patients and the elderly. ■ Use phenothiazines with extreme caution in pediatric patients with a history of sleep apnea, a family history of SIDS, or in the presence of Reye's syndrome. ■ May contain sulfites; use caution in patients with asthma. ■ Taper dose gradually following high dose or extended therapy to prevent possible occurrence of withdrawal symptoms (e.g., dizziness, gastritis, nausea, tremors, and vomiting).

Monitor:

Keep patient in supine position throughout treatment and for at least 30 minutes after treatment. Ambulate slowly and carefully; may cause postural hypotension. ■ Monitor BP and pulse before and during administration and between doses. ■ Cough reflex is often depressed; monitor closely if nauseated or vomiting to prevent aspiration. ■ Anticholinergic and cardiac effects may be troublesome during anesthesia. For patients receiving phenothiazines, taper and discontinue preoperatively if they will not be continued after surgery. ■ May discolor urine pink to reddish brown. ■ Photosensitivity of skin is possible. ■ See Drug/Lab Interactions.

Patient Education:

Request assistance for ambulation; may cause dizziness or fainting. ■ Observe caution when performing tasks that require alertness. ■ Avoid use of alcohol and other CNS depressants (e.g., diazepam, narcotics). ■ Possible eye and skin photosensitivity. Avoid unprotected exposure to sun. ■ Urine may discolor to pink or reddish brown.

Maternal/Child:

See Precautions and Contraindications. ■ Category C: use during pregnancy only when clearly needed. Use near term may cause maternal hypotension and adverse neonatal effects (e.g., extrapyramidal syndrome, hyperreflexia, hyporeflexia, jaundice). ■ Fetuses and infants have a reduced capacity to metabolize and eliminate; may cause embryo toxicity, increase neonatal mortality, or cause permanent neurologic damage.

May contain benzyl alcohol; use not recommended in neonates. ■ Not recommended during breast-feeding. Increases risk of dystonia and tardive dyskinesia. ■ Pediatric patients metabolize antipsychotic agents more rapidly than adults and are at increased risk to develop extrapyramidal actions, especially during acute illness (e.g., chickenpox, CNS infections, dehydration, gastroenteritis, measles); monitor closely.

Elderly:

See Dose Adjustments and Precautions. ■ Have a reduced capacity to metabolize and eliminate. May have increased sensitivity to postural hypotension, anticholinergic and sedative effects. ■ Increased risk of extrapyramidal side effects (e.g., tardive dyskinesia, parkinsonism).

DRUG/LAB INTERACTIONS

Use with **epinephrine** not recommended; may cause precipitous hypotension. ■ Use with **agents that produce hypotension** (e.g., antihypertensives, benzodiazepines, diuretics, lidocaine, paclitaxel) may produce severe hypotension. ■ Increased CNS, respiratory depression, and hypotensive effects with **CNS depressants** (e.g., narcotics, alcohol, anesthetics, and barbiturates); reduced doses of these agents usually indicated. ■ Chlorpromazine does not potentiate the anticonvulsant actions of **barbiturates.** Doses of **anticonvulsant barbiturates** should not be decreased if chlorpromazine is introduced. Instead begin chlorpromazine at a lower dose and titrate to effect. ■ Chlorpromazine may lower the seizure threshold. It may also interfere with **phenytoin and valproic acid** clearance, increasing potential for toxicity. Dose adjustment of anticonvulsants may be necessary. ■ Additive effects with **MAO inhibitors** (e.g., selegiline), **anticholinergics, antihistamines, antihypertensives, hypnotics, muscle relaxants, rauwolfia alkaloids, and thiazide diuretics;** dose adjustment may be necessary. ■ **Barbiturates** may also increase metabolism of chlorpromazine and reduce its effects. ■ Risk of cardiotoxicity increased with **pimozide**; concurrent use not recommended. ■ Risk of additive QT interval prolongation, cardiac depressant effects, and cardiac arrhythmias increased with **disopyramide, erythromycin, probucol, procainamide, and quinidine**. ■ Concurrent use with **antidepressants, tricyclic antidepressants, or MAO inhibitors** (e.g., selegiline) may increase effects of both drugs; risk of NMS may be increased. ■ Use with **antithyroid drugs** may increase risk of agranulocytosis. ■ May inhibit antiparkinson effects of **levodopa.** ■ May decrease pressor response to **ephedrine.** ■ May increase anticholinergic effect of **orphenadrine**. ■ May decrease effects of **oral anticoagulants.** ■ Concurrent use with **haloperidol, droperidol, or metoclopramide** may cause increased extrapyramidal effects. ■ Use with **metrizamide** (Amipaque) may lower seizure threshold; discontinue chlorpromazine 48 hours before myelography and do not resume for 24 hours after test is completed. ■ Metabolism and clearance of chlorpromazine is increased in cigarette **smokers;** decreased plasma levels and effectiveness may occur; dose adjustment of chlorpromazine may be indicated. ■ Decreased drowsiness may occur in cigarette **smokers.** May be offset by increased doses of chlorpromazine. ■ Use caution during anesthesia with **barbiturates** (e.g., methohexital, thiopental); may increase frequency and severity of hypotension and neuromuscular excitation. ■ Encephalopathic syndrome has been reported with concurrent use of **lithium;** monitor for S/S of neurologic toxicity. ■ Capable of innumerable other interactions. ■ May cause false-positive **pregnancy test** and false-positive **amylase, PKU, and other urine tests.**

SIDE EFFECTS

Usually transient if drug is discontinued, but may require treatment if severe. Anaphylaxis, cardiac arrest, distorted Q and T waves, drowsiness, excitement, extrapyramidal symptoms (e.g., abnormal positioning, extreme restlessness, pseudoparkinsonism, weakness of extremities), fever, hematologic toxicities (e.g., agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia), hypersensitivity reactions, hypertension, hypotension (occurs less frequently in smokers), melanosis, photosensitivity, tachycardia, tardive dyskinesia, and many others.

Overdose:

Can cause convulsions, hallucinations, and death.

ANTIDOTE

Discontinue the drug at onset of any side effect and notify the physician. Discontinue chlorpromazine and all drugs not essential to concurrent therapy immediately if NMS occurs. Will require intensive symptomatic treatment, medical monitoring, and management of concomitant medical problems. Counteract hypotension with norepinephrine or phenylephrine and IV fluids. Counteract extrapyramidal symptoms with benztropine or diphenhydramine. Use diazepam followed by phenytoin for convulsions or hyperactivity. Maintain a clear airway and adequate hydration. Epinephrine is contraindicated for hypotension; further hypotension will occur. Phenytoin may be helpful in ventricular arrhythmias. Avoid analeptics such as caffeine and sodium benzoate in treating respiratory depression and unconsciousness; they may cause convulsions. Resuscitate as necessary. Not removed by dialysis.

CIDOFOVIR INJECTION BBW

(sih-**DOF**-oh-veer in-**JEK**-shun)
Vistide
Antiviral (nucleotide analog)
pH 6.7 to 7.6

USUAL DOSE

Pretreatment requirements:

24 to 48 hours before each cidofovir infusion, obtain SCr, urine protein (via dipstick or quantitative urinalysis), and CBC with differential (absolute neutrophil count [ANC]).

Probenecid:

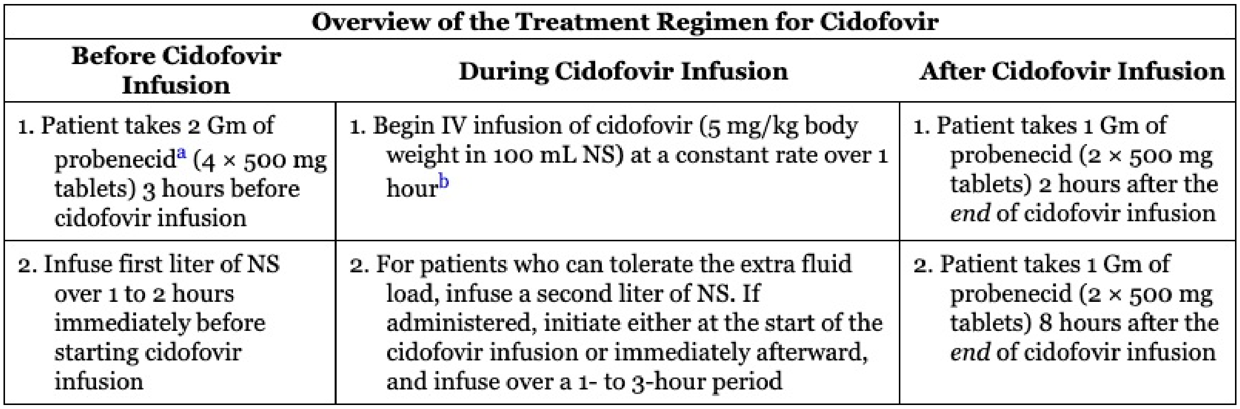
A specific protocol is required; see the following chart. A 4-Gm course of oral probenecid is required on the day of each infusion of cidofovir to reduce the risk of renal impairment. ***Hydration:*** Hydration with 1 to 2 liters of NS is required to help reduce proteinuria and prevent increases in SCr. Infrequent dosing schedule may eliminate need for an indwelling IV catheter, reducing discomfort and potential for infection.

Induction:

5 mg/kg in 100 mL NS once weekly for 2 consecutive weeks.

Maintenance:

5 mg/kg in 100 mL NS once every other week.



Overview of the Treatment Regimen for Cidofovir

Before Cidofovir Infusion	During Cidofovir Infusion	After Cidofovir Infusion
1. Patient takes 2 Gm of probenecid[a] (4 × 500 mg tablets) 3 hours before cidofovir infusion	1. Begin IV infusion of cidofovir (5 mg/kg body weight in 100 mL NS) at a constant rate over 1 hour[b]	1. Patient takes 1 Gm of probenecid (2 × 500 mg tablets) 2 hours after the *end* of cidofovir infusion
2. Infuse first liter of NS over 1 to 2 hours immediately before starting cidofovir infusion	2. For patients who can tolerate the extra fluid load, infuse a second liter of NS. If administered, initiate either at the start of the cidofovir infusion or immediately afterward, and infuse over a 1- to 3-hour period	2. Patient takes 1 Gm of probenecid (2 × 500 mg tablets) 8 hours after the *end* of cidofovir infusion

[a] Patients receiving concomitant probenecid and zidovudine should temporarily discontinue zidovudine or decrease the zidovudine dose by 50% on days of combined zidovudine and probenecid administration.

[b] The recommended dosage, frequency, or infusion rate must not be exceeded.

DOSE ADJUSTMENTS

Reduce dose to 3 mg/kg for the remainder of therapy, if SCr increases by 0.3 to 0.4 mg/dL above baseline. ■ 5 mg/kg may be given to patients who develop a 2^+ proteinuria but have a stable SCr. Encourage oral hydration; additional IV hydration may be appropriate. ■ Discontinue cidofovir if the SCr increases by 0.5 mg/dL or more above baseline or if proteinuria 3^+ or more develops. ■ Restarting cidofovir in patients whose renal function has returned to baseline after a SCr elevation of more than 0.5 mg/dL is not recommended. ■ Discontinue cidofovir in any patient who requires therapy with a nephrotoxic agent; see Contraindications. Cidofovir may be restarted after other nephrotoxic therapy is complete, an adequate washout period of at least 7 days has passed, and adequate renal function (SCr less than 1.5 mg/dL) is confirmed.

DILUTION

Specific techniques required; see Precautions.

A calculated dose must be diluted in 100 mL of NS.

Storage:

Store unopened vials at CRT. May be refrigerated but must be used within 24 hours of dilution with NS. Allow to return to room temperature before administration. Discard partially used vials.

COMPATIBILITY

Manufacturer states, “**Compatibility** with Ringer’s solution, LR, or bacteriostatic IV fluids not evaluated; no data available to support the addition of other drugs or supplements for concurrent administration.”

RATE OF ADMINISTRATION

A single dose as an infusion at a constant rate over 1 hour. Use of an infusion pump is recommended.

ACTIONS

A nucleotide analog antiviral. Its active intracellular metabolite selectively inhibits CMV DNA synthesis. It is incorporated into the growing viral DNA chain, resulting in reductions in the rate of viral DNA synthesis. This action is independent of virus infection (acyclovir or ganciclovir require activation by a virally encoded enzyme). Elimination half-life is short (2.6 hours), but it has a long intracellular half-life, which permits infrequent dosing. Primarily excreted in urine (70% to 85% in 24 hours with concomitant doses of probenecid).

INDICATIONS AND USES

Treatment of newly diagnosed or relapsing CMV retinitis in patients with AIDS is the only approved indication.

CONTRAINDICATIONS

Pre-existing renal dysfunction (e.g., baseline SCr more than 1.5 mg/dL, calculated CrCl equal to or less than 55 mL/min, or a urine protein equal to or greater than 100 mg/dL [equivalent to a 2^+ or more proteinuria]). ■ Patients receiving agents with nephrotoxic potential (e.g., aminoglycosides, amphotericin B, foscarnet, NSAIDs, IV pentamidine, vancomycin). No other nephrotoxic agent should be administered within 7 days of starting cidofovir or concomitantly during cidofovir therapy. ■ Hypersensitivity to cidofovir and/or a history of clinically severe hypersensitivity (e.g., hypotension, respiratory distress) to probenecid or other sulfa-containing medications (e.g., sulfamethoxazole/trimethoprim).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist, preferably in an environment where emergency treatment is available. ■ This formulation is for IV use only; **DO NOT** use for intraocular injection. ■ Safety and effectiveness have not been established for treatment of other CMV infections (e.g., pneumonitis, gastroenteritis, congenital or neonatal CMV disease) or for CMV disease in non–HIV-infected individuals. ■ Calculated CrCl may not accurately estimate renal function in emaciated (e.g., patients with AIDS) or extremely muscular patients; a 24-hour urine collection may be required. ■ CMV resistant to ganciclovir may also be resistant to cidofovir, but may be sensitive to foscarnet (Foscavir). ■ CMV resistant to foscarnet (Foscavir) may be sensitive to cidofovir. ■ Nephrotoxicity is dose limiting and is the major toxicity of cidofovir. Do not exceed recommended dose, frequency, or rate of administration; may cause increased risk of renal toxicity. Acute renal failure requiring dialysis or contributing to death has occurred with as few as 1 or 2 doses of cidofovir. ■ Renal function may not return to baseline after treatment with cidofovir. ■ Proteinuria is an early indicator of nephrotoxicity; continued administration of cidofovir may lead to additional proximal tubular cell injury resulting in glycosuria, decreased serum phosphate, uric acid, and bicarbonate; increased SCr; and/or acute renal failure, which may necessitate dialysis. ■ May cause granulocytopenia (e.g., neutropenia). ■ Although some reference sources have published doses for patients with impaired renal function, this drug is contraindicated in such patients and should be given only to those who meet specific dosing criteria; see Contraindications.

Monitor:

24 to 48 hours before each cidofovir infusion, obtain SCr, urine protein (via dipstick or quantitative urinalysis), and CBC with differential (absolute neutrophil count [ANC]). Repeat between doses if indicated. ■ Administration of probenecid as ordered and adequate hydration (oral and IV) are imperative. ■ Antiretroviral therapy may be continued with the exception of zidovudine; see Drug/Lab Interactions. ■ Probenecid frequently causes fever, flushing, headache, nausea with or without emesis, and rash. Use acetaminophen for prophylaxis or treatment of fever or headache. Encourage ingestion of food before each dose of probenecid to reduce nausea; prophylactic antiemetics (e.g., ondansetron) are appropriate. Consider use of antihistamines (e.g., diphenhydramine) for prophylaxis or treatment in patients who develop mild hypersensitivity reactions (e.g., rash). Severe hypersensitivity reactions (e.g., laryngospasm, hypotension) have occasionally been reported with probenecid. Usually occur within several hours after patients have received probenecid even though they have received it before with no adverse reactions. Observe patient carefully for hypersensitivity reactions. Treatment for anaphylaxis (e.g., epinephrine, corticosteroids, and antihistamines) must be readily available. ■ Monitor intraocular pressure, visual acuity, and ocular symptoms with a baseline ophthalmologic exam and periodically during therapy. Uveitis or iritis has been reported; may be treated with topical steroids. Risk of increased intraocular pressure and other visual problems may be increased in patients with pre-existing diabetes mellitus. ■ Use of the Cockcroft-Gault formula is recommended if a precise estimate of CrCl measurement is indicated.

Patient Education:

Not a cure for CMV retinitis. Retinitis may recur during maintenance or after treatment; regular ophthalmologic exams imperative. ■ Full compliance with regimen imperative (e.g., probenecid with food, increased IV and oral hydration, regular lab testing). ■ Report diarrhea, eye pain or change in vision, fever, headache, loss of appetite, rash, nausea, and vomiting promptly. ■ Report concomitant medication changes or additions. ■ Notify all health care personnel of treatment with probenecid to avoid interactions. ■ Consider birth control options; see Precautions and Maternal/Child.

Maternal/Child:

Category C: should not be used during pregnancy; embryotoxic in animals. A potential carcinogen; knowledge of effects on women unknown. ■ Women of childbearing age should use effective contraception during cidofovir therapy and for 1 month after completion. ■ Men should use barrier contraception during cidofovir therapy and for 3 months after completion. ■ Has caused reduced testicular weight and hypospermia in animals. ■ Do not administer to nursing mothers. HIV-infected mothers are advised not to breast-feed to avoid transmission to an uninfected child. ■ Safety and effectiveness for use in pediatric patients not established. Use in pediatric patients with extreme caution and only if the benefits of treatment outweigh the risks of long-term carcinogenicity and reproductive toxicity. Consult physician specialist for adjustments in probenecid and hydration.

Elderly:

Effects have not been studied; monitor renal function carefully.

DRUG/LAB INTERACTIONS

Limited information available. Drug profile review by pharmacist imperative. ■ Nephrotoxicity increased by other **nephrotoxic agents** (e.g., aminoglycosides [e.g., amikacin, gentamicin], amphotericin B, foscarnet, IV pentamidine, NSAIDs, vancomycin); see Contraindications. ■ Prior treatment with **foscarnet** may also increase the risk of nephrotoxicity; monitor renal function carefully. ■ **Probenecid** decreases clearance of zidovudine; temporarily discontinue or reduce dose of zidovudine by 50% on days of combined zidovudine and probenecid administration. ■ **Probenecid** may have interactions with numerous other drugs (e.g., **acetaminophen, acyclovir, ACE inhibitors, aminosalicylic acid, barbiturates, benzodiazepines, bumetanide, chlorpropamide, clofibrate, ddC, famotidine, furosemide, methotrexate, NSAIDs, theophyllines**), usually decreasing their rate of excretion and increasing toxicity. Consider withholding any drug that may interact with probenecid on the day of cidofovir administration.

SIDE EFFECTS

Nephrotoxicity is dose limiting. Metabolic acidosis (Fanconi syndrome), neutropenia, and ocular hypotony may be dose limiting and require prompt treatment. Anorexia, asthenia, chills, decreased intraocular pressure, decreased serum bicarbonate, diarrhea, dyspnea, fever, headache, increased creatinine, infection, nausea and vomiting, ophthalmic effects (e.g., change in vision, eye pain, increased sensitivity to light, reddened eyes), pneumonia, proteinuria, rash, and unusual tiredness or weakness may occur.

ANTIDOTE

There is no specific antidote. Keep physician informed. Adequate hydration, use of probenecid, and careful monitoring will help to reduce potential for renal impairment and may minimize other side effects. Filgrastim may be used to treat neutropenia. See Monitor for management of probenecid side effects. Discontinue cidofovir based on criteria in Dose Adjustments. Treat overdose for 3 to 5 days with probenecid 1 Gm three times daily and vigorous IV hydration to tolerance. Treat anaphylaxis and resuscitate as indicated. Hemodialysis may be helpful in overdose. High-flux hemodialysis has reduced serum level of cidofovir by up to 75%.

CIPROFLOXACIN BBW

(sip-row-**FLOX**-ah-sin)
Cipro IV
Antibacterial (fluoroquinolone)
pH 3.5 to 4.6

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Dose and duration based on severity and nature of the infection, susceptibility of the causative organsim. Usual dose is 200-400 every 8-12 hours.

PEDIATRIC DOSE

Used only when alternate therapy cannot be used; see Precautions and Maternal/Child. ***In all situations, do not exceed an IV dose of 400 mg.***

Inhalation anthrax (postexposure):

10 mg/kg every 12 hours IV. Do not exceed 400 mg/dose IV. Begin administration as soon as possible after suspected or confirmed exposure. May transfer to oral therapy when appropriate with a dose of 15 mg/kg PO every 12 hours. Do not exceed a 500-mg dose PO. Administer for 60 days.

Complicated UTIs or pyelonephritis in patients from 1 to 17 years of age:

Dosing and initial route (IV or PO) should be determined by severity of infection. 6 to 10 mg/kg IV every 8 hours. Do not exceed 400 mg/dose IV. May transfer to oral therapy with a dose of 10 to 20 mg/kg PO every 12 hours at discretion of physician. Do not exceed a 750-mg dose PO. Total duration of treatment is 10 to 21 days.

Plague:

10 mg/kg every 8 to 12 hours IV. Do not exceed 400 mg/dose IV. Begin administration as soon as possible after suspected or confirmed exposure. May transfer to oral therapy when appropriate with a dose of 15 mg/kg PO every 8 to 12 hours. Do not exceed a 500-mg dose PO. Administer for 10 to 21 days.

Pulmonary exacerbations of cystic fibrosis in patients from 5 to 17 years of

age (unlabeled):

10 mg/kg/dose IV every 8 hours. Do not exceed 400 mg/dose. May transfer to oral therapy when appropriate at a dose of 20 mg/kg/dose PO every 12 hours; see Monitor.

DOSE ADJUSTMENTS

Increase interval between doses (200 to 400 mg every 18 to 24 hours) if CrCl is less than 30 mL/min (see literature for additional information). ■ Information on dosing adjustments for pediatric patients with renal insufficiency is not available. ■ Dose reduction not required based on age; see Elderly. ■ See Drug/Lab Interactions.

DILUTION

Available prediluted in D5W in latex-free plastic infusion containers ready for use. A clear, colorless to slightly yellow solution. Do not hang plastic containers in series; may cause air embolism. Also available in 20- and 40-mL vials containing 10 mg/mL (1% solution), which must be diluted with NS, D5W, SWFI, D10W, D5/¼NS, D5/½NS, or LR to a final concentration of 1 to 2 mg/mL.

Filters:

No recommendations available from manufacturer.

Storage:

Store vials between 5° and 30° C (41° and 86° F). Store flexible containers and vials between 5° and 25° C (41° and 77° F); protect from light, excessive heat, and freezing. Vials diluted in recommended solutions are stable for up to 14 days refrigerated or at room temperature if the final diluted concentration is between 0.5 and 2 mg/mL.

COMPATIBILITY

Manufacturer recommends temporarily discontinuing other solutions infusing at the same site during intermittent infusion through a **Y-site** or volume control and that ciprofloxacin be administered separately and the IV line be flushed before and after administration of any other drug.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose must be equally distributed over 60 minutes as an infusion. Too-rapid administration and/or the use of a small vein may increase incidence of local site inflammation and other side effects. May be given through a Y-tube or three-way stopcock of infusion set. Temporarily discontinue other solutions infusing at the same site.

ACTIONS

A synthetic, broad-spectrum antimicrobial agent, a fluoroquinolone. Bactericidal to a wide range of aerobic gram-negative and gram-positive organisms through interference with the enzymes needed for bacterial DNA replication, transcription, repair, and recombination. Onset of action is prompt, and serum levels are dose related. Half-life averages 5 to 6 hours. Readily distributed to body fluids (saliva, nasal and bronchial secretions, sputum, skin blister fluid, lymph, peritoneal fluid, bile and prostatic secretions). Found in lung, skin, fat, muscle, cartilage, and bone. Levels in cerebrospinal fluid and eye fluids are lower than plasma levels. Limited metabolism. Excreted primarily as unchanged drug in the urine, usually within 24 hours. A small amount is excreted in the bile and feces. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of infections caused by susceptible isolates of designated organisms in the conditions and patient populations listed below. ■ Treatment of skin and skin structure infections in adults. ■ Treatment of bone and joint infections in adults. ■ Treatment of complicated intra-abdominal infections in adults (used in combination with metronidazole). ■ Treatment of nosocomial pneumonia in adults. ■ Empiric treatment of febrile neutropenia in adults (used in combination with piperacillin sodium). ■ Treatment of inhalational anthrax (postexposure) to reduce the incidence or progression of disease in adults or pediatric patients following exposure to aerosolized *Bacillus anthracis* (Anthrax). ■ Treatment of plague (including pneumonic and septicemic plague) due to *Yersinia pestis*, and prophylaxis for plague in adults and pediatric patients from birth to 17 years of age. ■ Treatment of chronic bacterial prostatitis in adults. ■ Treatment of lower respiratory infections in adults (***not*** the drug of first choice in treatment of presumed or confirmed pneumonia secondary to *Streptococcus pneumoniae*). ■ Treatment of acute exacerbations of chronic bronchitis (AECB) in adults. Because ciprofloxacin has been associated with serious adverse reactions and because for some patients AECB is self-limiting, reserve ciprofloxacin for treatment of AECB in patients who have no alternative treatment options. ■ Treatment of urinary tract infections in adults. ■ Treatment of complicated UTI and pyelonephritis due to *Escherichia coli* in pediatric patients 1 to 17 years of age. Although effective, ciprofloxacin is not the drug of first choice because of an increased incidence of adverse reactions compared with controls; see Maternal/Child. ■ Treatment of acute sinusitis in adults. Because ciprofloxacin has been associated with serious adverse reactions and because for some patients acute sinusitis is self-limiting, reserve ciprofloxacin for treatment of acute sinusitis in patients who have no alternative treatment options. ■ Oral route of administration indicated for treatment of other infections (e.g., infectious diarrhea, typhoid fever, urethral and cervical gonococcal infections).

Unlabeled uses:

Cystic fibrosis. ■ Infective endocarditis. ■ Surgical prophylaxis. ■ Tularemia.

CONTRAINDICATIONS

Known hypersensitivity to ciprofloxacin or any other quinolone antimicrobial agent (e.g., levofloxacin) or any of the product components. ■ Concomitant administration with tizanidine is contraindicated.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, ciprofloxacin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Specific culture and sensitivity studies indicated to determine susceptibility of the causative organism to ciprofloxacin. ■ The emergence of bacterial resistance to fluoroquinolones and the occurrence of cross-resistance with other fluoroquinolones have been observed and are of concern. Proper use of fluoroquinolones and other classes of antibiotics is encouraged to avoid the emergence of resistant bacteria from overuse. ■ *Pseudomonas aeruginosa* may develop resistance during treatment. Ongoing culture and sensitivity studies indicated. ■ If anaerobic organisms are suspected of contributing to the infection, appropriate therapy should be administered. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. Monitor carefully. ■ Fluoroquinolones, including ciprofloxacin, have been associated with disabling and potentially irreversible serious adverse reactions that have occurred together in the same patient. Commonly seen adverse reactions include tendinitis and tendon rupture, arthralgia, myalgia, peripheral neuropathy, changes in blood glucose levels, and CNS effects (e.g., anxiety, confusion, depression, hallucinations, insomnia, severe headaches). These reactions can occur within hours to weeks after starting ciprofloxacin and have been seen in patients of any age and in patients without any pre-existing risk factors. Discontinue ciprofloxacin immediately and avoid the use of fluoroquinolones, including ciprofloxacin, in patients who experience any of these serious adverse reactions. ■ Fluoroquinolones, including ciprofloxacin, have been associated with an increased risk of seizures (convulsions), increased intracranial pressure (pseudotumor cerebri), dizziness, and tremors. May trigger seizures or lower the seizure threshold. Use caution in patients with epilepsy or known or suspected CNS disorders that may predispose them to seizures or lower the seizure threshold (e.g., severe cerebral arteriosclerosis, previous history of convulsion, reduced cerebral blood flow, altered brain structure, or stroke) or in the presence of other risk factors that may predispose them to seizures (e.g., drugs that may lower the seizure threshold, renal dysfunction). ■ Fluoroquinolones, including ciprofloxacin, have been associated with an increased risk of psychiatric adverse reactions that include toxic psychosis, psychotic reactions progressing to suicidal ideations/thoughts, hallucinations, or paranoia; depression; or self-injurious behavior such as attempted or completed suicide; anxiety, agitation, or nervousness; confusion, delirium, disorientation, or disturbances in attention; insomnia or nightmares; and memory impairment. These reactions may occur following the first dose. ■ Tendinitis and tendon rupture that required surgical repair or resulted in prolonged disability have been reported in patients of all ages receiving quinolones. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Inflammation and tendon rupture may occur during or up to months after fluoroquinolone therapy and may occur bilaterally. Risk may be increased in patients over 60 years of age; in patients taking corticosteroids; in patients with heart, kidney, or lung transplants; with strenuous physical activity; and in patients with renal failure or previous tendon disorders such as rheumatoid arthritis. Avoid ciprofloxacin in patients who have a history of tendon disorders or have experienced tendinitis or tendon rupture. Discontinue ciprofloxacin immediately if patient experiences pain, swelling, inflammation, or rupture of a tendon. ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in patients with myasthenia gravis. Serious adverse events, including requirement for ventilatory support and deaths, have been reported in patients with myasthenia gravis. Avoid use in patients with a known history of myasthenia gravis. ■ Fluoroquinolones, including ciprofloxacin, have been associated with an increased risk of peripheral neuropathy. Cases of sensory or sensorimotor axonal polyneuropathy resulting in paresthesias, hypoesthesias, dysesthesias (impairment of sensitivity or touch), or weakness have been reported. Symptoms may occur soon after initiation of therapy and may be irreversible. Avoid ciprofloxacin in patients who have previously experienced peripheral neuropathy. ■ Serious and occasionally fatal hypersensitivity (anaphylactic) reactions have been reported. ■ Prolongation of the QT interval on ECG and infrequent cases of arrhythmia (including torsades de pointes) have been reported with the use of some fluoroquinolones, including ciprofloxacin. Avoid ciprofloxacin in patients with known prolongation of the QT interval, in patients with risk factors for QT prolongation or torsades de pointes (e.g., congenital long QT syndrome, uncorrected electrolyte imbalances [e.g., hypokalemia, hypomagnesemia], and cardiac disease [e.g., heart failure, MI, and significant bradycardia]), and in patients receiving concurrent treatment with Class 1A antiarrhythmic agents (e.g., quinidine, procainamide), Class III antiarrhythmic agents (e.g., amiodarone, sotalol), tricyclic antidepressants, macrolides, or antipsychotics. ■ Other serious events (sometimes fatal) due to hypersensitivity or uncertain etiology have been reported with fluoroquinolones, including ciprofloxacin. Manifestations may include allergic pneumonitis, renal or hepatic impairment/failure, hematologic toxicity, and dermatologic toxicity; see Side Effects, Post-Marketing. These reactions usually occur following administration of multiple doses. Discontinue ciprofloxacin at the first appearance of a skin rash, jaundice, or other signs of hypersensitivity. Cases of severe hepatic toxicity, including necrosis, life-threatening hepatic failure, and fatal events have been reported. Acute liver injury is rapid in onset (range 1 to 39 days) and is often associated with hypersensitivity. Temporary increase in transaminases, alkaline phosphatase, or cholestatic jaundice, especially in patients with previous liver damage, has also been reported. ■ Epidemiologic studies report an increased rate of aortic aneurysm and dissection within 2 months after use of fluoroquinolones, particularly in elderly patients. In patients with a known aortic aneurysm or in patients who are at greater risk for aortic aneurysms, ciprofloxacin use should be limited to cases in which no alternative antibacterial treatments are available. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with ciprofloxacin. ■ Moderate to severe photosensitivity/phototoxicity reactions have been reported in patients receiving quinolones; see Patient Education. ■ Fluroquinolones, including ciprofloxacin, have been associated with disturbances of blood glucose, including symptomatic hyperglycemia and hypoglycemia, usually in diabetic patients receiving concomitant treatment with an oral hypoglycemic agent (e.g., glyburide) or with insulin. In these patients, careful monitoring of blood glucose is recommended. Severe cases of hypoglycemia resulting in coma or death have been reported. Ciprofloxacin and other quinolones should be reserved for cases in which no other drugs are available.

Monitor:

Monitor for S/S of hypersensitivity reaction (e.g., cardiovascular collapse, dyspnea, itching, loss of consciousness, pharyngeal or facial edema, tingling, urticaria). May cause anaphylaxis with the first or succeeding doses, even in patients without known hypersensitivity. Emergency equipment must always be available. ■ Monitor for S/S of peripheral neuropathy. Discontinue ciprofloxacin at the first symptoms of neuropathy (e.g., pain, burning, tingling, numbness, and/or weakness) or if patient is found to have deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ Monitor for CNS adverse effects, including altered mental status, seizures, and changes in mood or behavior. ■ Monitor for S/S of tendinitis or tendon rupture. ■ ECG monitoring for QT prolongation may be indicated in selected patients. ■ Maintain adequate hydration and acidity of urine throughout treatment. Can form crystals in concentrated alkaline urine. ■ Monitor hematopoietic, hepatic, and renal systems during prolonged treatment. Patients with severe infections and severe renal impairment and hepatic insufficiency require careful monitoring. ■ Monitor blood glucose, especially in diabetic patients. ■ Use of large veins recommended to reduce incidence of local irritation. Symptoms of local irritation do not preclude further administration of ciprofloxacin unless they recur or worsen. Generally resolve when infusion complete. ■ Concomitant use with theophylline may cause serious and fatal reactions, including cardiac arrest, respiratory failure, seizures, and/or status epilepticus. If concomitant use cannot be avoided, monitor serum levels of theophylline and adjust dose as indicated. ■ Doses will increase slightly with transfer to oral ciprofloxacin (e.g., 200 mg IV every 12 hours equals 250 mg PO every 12 hours; 400 mg IV every 12 hours equals 500 mg PO every 12 hours; 400 mg IV every 8 hours equals 750 mg PO every 12 hours). ■ See Drug/Lab Interactions.

Patient Education:

A patient medication guide is available from the manufacturer. ■ Discontinue ciprofloxacin and promptly report the development of any severe adverse reaction. ■ Capable of numerous drug interactions. Review all prescription and nonprescription medications with your health care provider. ■ Inform physician of any history of myasthenia gravis. Patients with a history of myasthenia gravis should avoid using ciprofloxacin. ■ Photosensitivity has been reported. Avoid excessive sunlight or artificial ultraviolet light. May cause severe sunburn; wear protective clothing, use sunscreen, and wear dark glasses outdoors. Report a sunburn-like reaction or skin eruption promptly. ■ Effects of caffeine- or theophylline-containing preparations may be increased; promptly report difficulty breathing, palpitations, and/or seizures. Limit or eliminate concurrent use. Monitor if concurrent use is necessary. ■ Promptly report tendon pain or inflammation, weakness, or the inability to use a joint; rest and refrain from exercise. Symptoms may be irreversible. ■ Promptly report skin rash or any other hypersensitivity reaction. ■ Promptly report pain, burning, tingling, numbness, and/or weakness. Nerve damage can be permanent. ■ Promptly report development of any CNS side effects (e.g., convulsions, dizziness, light-headedness, change in mood or behavior). ■ Inform physician of any history of seizures. ■ Request assistance with ambulation; may cause dizziness and light-headedness. Use caution in tasks that require alertness. ■ Parents should inform physician of any history of joint-related problems and should promptly report any joint-related problems that develop during or after therapy. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Promptly report any S/S of hepatic toxicity (e.g., dark-colored urine, fever, itching, light-colored bowel movement, loss of appetite, nausea, right upper quadrant tenderness, tiredness, weakness, yellowing of skin). ■ May prolong QT interval. Review medications and medical history. ■ Drink fluids liberally to avoid formation of highly concentrated urine and crystal formation. ■ Seek emergency medical care if sudden chest, stomach, or back pain is experienced. ■ Diabetic patients taking oral hypoglycemic agents or insulin should discontinue ciprofloxacin and contact their provider if they experience a hypoglycemic reaction.

Maternal/Child:

Category C: use during pregnancy only if benefits justify potential risk to fetus and mother. ■ Discontinue breast-feeding. ■ May erode cartilage of weight-bearing joints or cause other signs of arthropathy (arthralgia, arthritis) in infants and children. Indicated for treatment of complicated UTIs or pyelonephritis. Although effective, it is not the drug of first choice for this indication due to adverse reactions. Also indicated for inhalation anthrax (postexposure) and for treatment of and prophylaxis for the plague. The risk-benefit assessment indicates that administration of ciprofloxacin for these indications is appropriate. ■ Has been used in infants and children to treat serious infections unresponsive to other antibiotic regimens.

Elderly:

Safety and effectiveness similar to younger adults. ■ May be at increased risk of experiencing side effects (e.g., aortic aneurysm and dissection, CNS effects, drug-associated effects on the QT interval, tendinitis, tendon rupture); see Precautions. Half-life may be slightly extended because of age-related renal impairment; see Dose Adjustments. Monitoring of renal function may be useful.

DRUG/LAB INTERACTIONS

Review of patient medication profile required. ■ Ciprofloxacin is an inhibitor of the hepatic CYP1A2 enzyme pathway. Coadministration with other drugs metabolized by this route, such as **clozapine, methylxanthines** (e.g., theophylline), **olanzapine, ropinirole, tizanidine,** or **zolpidem**, results in increased plasma concentrations of these drugs, which may cause significant toxicity. ■ **Concomitant administration with tizanidine is contraindicated** (hypotensive and sedative effects potentiated). ■ Concurrent use with **zolpidem** is not recommended. ■ May cause serious or fatal reactions with **theophylline** (e.g., cardiac arrhythmias or arrest, respiratory failure, or seizures). If must be used concomitantly, monitor serum levels of theophylline and decrease dose as appropriate. Observe closely with **caffeine** intake; has caused similar problems. Elevated serum levels of other xanthine derivatives (e.g., pentoxifylline-containing products) have also been seen with concurrent use. ■ Use with **cyclosporine** may cause an increase in SCr and nephrotoxic effects. Monitor SCr if concurrent use required. ■ May potentiate **oral anticoagulants** (e.g., warfarin); monitor PT/INR. ■ Potentiated by **probenecid**. Use with caution and monitor for possible ciprofloxacin toxicity. ■ Severe hypoglycemia has been reported with concomitant use of **oral antidiabetic agents** (e.g., glyburide, glimepiride); monitor serum glucose levels. ■ May increase or decrease serum **phenytoin** levels; monitor phenytoin levels with concomitant use and repeat phenytoin levels shortly after completion of ciprofloxacin therapy. ■ Risk of CNS stimulation and seizures may be increased with concurrent use of **NSAIDs** with high doses of quinolones. ■ Concurrent use with **methotrexate** requires close monitoring. May inhibit renal tubular transport of methotrexate, thereby increasing methotrexate serum levels and the risk of toxicity. ■ Coadministration with **drugs that prolong the QT interval** such as **Class IA or III antiarrhythmic agents** (e.g., amiodarone, disopyramide, procainamide, quinidine), **tricyclic antidepressants, macrolide antibiotics**, and **antipsychotics** may increase the risk of QT prolongation and life-threatening arrhythmias. Concurrent use is not recommended. ■ Fivefold increase in **duloxetine** exposure with concurrent use. Avoid use if possible. If must be given concurrently, monitor for duloxetine toxicity. ■ Twofold increase in **sildenafil** exposure. Use with caution. ■ May cause a false-positive when **testing urine for opiates;** more specific testing methods may be indicated. ■ See Side Effects.

SIDE EFFECTS

Central nervous system disturbances, diarrhea, eosinophilia, headache, hepatic enzyme abnormalities (elevation of alkaline phosphatase, AST, ALT, LDH, serum bilirubin), local IV site reactions, nausea and vomiting, rash, and restlessness are reported most frequently. Other less frequent reactions include abdominal pain; allergic reactions (e.g., anaphylaxis, cardiovascular collapse, death, dyspnea, edema [facial, pharyngeal, or pulmonary], fever, itching, loss of consciousness, urticaria); cardiovascular effects (e.g., cardiac arrest, QT interval prolongation, tachycardia, torsades de pointes, vasodilation); CDAD; CNS effects (e.g., confusion, depression, hallucinations, light-headedness, seizures, tingling, toxic psychosis, tremors); crystalluria; elevated platelet counts, BUN, serum amylase, serum creatinine, serum creatine phosphokinase, serum potassium, uric acid, and triglycerides; hyperglycemia; hypoglycemia; increased intracranial pressure; peripheral neuropathy (e.g., pain, burning, tingling, numbness and/or weakness [see Precautions, Monitor]); photosensitivity/phototoxicity and vision changes; respiratory arrest; status epilepticus; tendinitis; and tendon rupture. Capable of numerous other reactions in fewer than 1% of patients.

Post-Marketing:

Acute generalized exanthematous pustulosis (AGEP), allergic pneumonitis, arthralgia, exacerbation of myasthenia gravis, hematologic abnormalities (agranulocytosis, anemia [hemolytic and aplastic], leukopenia, pancytopenia, thrombocytopenia, thrombotic thrombocytopenic purpura), increased INR in patients treated with vitamin K antagonists, interstitial nephritis, liver abnormalities (e.g., acute hepatic necrosis or failure, hepatitis, jaundice), myalgia, polyneuropathy, serum sickness, severe dermatologic reactions (e.g., toxic epidermal necrolysis [Lyell's syndrome], Stevens-Johnson syndrome), vasculitis.

ANTIDOTE

Keep physician informed of all side effects. Many will require symptomatic treatment; monitor closely. Death may result from some of these side effects. Discontinue ciprofloxacin at the first appearance of a skin rash or major side effect (hypersensitivity, CDAD, CNS symptoms, dermatologic reactions, hepatoxicity, hypoglycemia, peripheral neuropathy, phototoxicity, or tendinitis or tendon rupture). Treat hypersensitivity reactions with epinephrine, airway management, oxygen, IV fluids, antihistamines (diphenhydramine), corticosteroids (hydrocortisone sodium succinate), and pressor amines (dopamine) as indicated. Treat CNS symptoms as indicated. Mild cases of CDAD may respond to discontinuation of ciprofloxacin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. In overdose, observe carefully, provide supportive treatment, maintain hydration, and monitor renal function and urinary pH and acidify, if required, to prevent crystalluria. No specific antidote; up to 10% may be removed by hemodialysis or peritoneal dialysis. Maintain patient until drug excreted.

CISATRACURIUM BESYLATE

(sis-ah-trah-**KYOU**-ree-um **BES**-ih-layt)
Nimbex, Nimbex PF
Neuromuscular blocking agent (nondepolarizing)
Anesthesia adjunct
pH 3.25 to 3.65

USUAL DOSE

Must be individualized. Must be used with adequate anesthesia and/or sedation and after unconsciousness induced. A peripheral nerve stimulator should be used to monitor drug effect, determine the need for additional doses, and confirm recovery from neuromuscular block.

Adjunct to Propofol/N_2O/O_2 Anesthesia for Adults (IV Bolus)

Initial dose:

0.15 to 0.2 mg/kg. 0.15 mg/kg should provide good to excellent conditions for intubation within 2 minutes and adequate muscle relaxation for 55 minutes (range 44 to 74 min). 0.2 mg/kg should be effective within 1.5 minutes and last for 61 minutes (range 41 to 81 min).

Maintenance dose:

May be given by IV bolus or as a continuous infusion. Determine need for maintenance dose based on beginning symptoms of neuromuscular blockade recovery determined by a peripheral nerve stimulator. Usually required 40 to 60 minutes after a bolus dose. Do not administer before recovery begins. Repeated doses have no cumulative effect if recovery is allowed to begin before administration. See Dose Adjustments. ***IV bolus:*** 0.03 mg/kg should provide an additional 20 minutes of muscle relaxation. Smaller or larger doses may be given based on expected duration of procedure.

Continuous infusion:

Begin infusion with 3 mcg/kg/min to rapidly counteract the spontaneous recovery, then decrease to 1 to 2 mcg/kg/min. Monitor maintenance infusion with a peripheral nerve stimulator.

Support of Intubated, Mechanically Ventilated Adult ICU Patients

After intubation is accomplished (usually with succinylcholine), an initial bolus dose of 0.1 mg/kg provides adequate neuromuscular blockade. Maintain with 3 mcg/kg/min (range 0.5 to 10.2 mcg/kg/min). Published reports describe a wide interpatient variability in dosing requirements that may change from day to day. Adjust infusion rate according to clinical assessment of the patient's response. Use of a peripheral nerve stimulator is recommended. Do not increase dose until there is a definite response to nerve stimulation. If recovery from neuromuscular block has progressed, readministration of a bolus dose may be necessary. Long-term use (beyond 6 days) has not been studied.

PEDIATRIC DOSE

See all comments under Usual Dose and Maternal/Child.

Adjunct to Halothane or Opioid Anesthesia for Pediatric Patients 1 Month to 23 Months of Age

0.15 mg/kg. Should produce maximum block in 2 minutes and adequate muscle relaxation for 43 minutes (range is 34 to 58 minutes).

Adjunct to Halothane or Opioid Anesthesia for Pediatric Patients 2 to 12 Years of Age

Initial dose:

0.1 to 0.15 mg/kg as an IV bolus. 0.1 mg/kg should provide good to excellent conditions for intubation within 2.8 minutes and adequate muscle relaxation for 28 minutes (range 21 to 38 minutes). 0.15 mg/kg should produce maximum block in 3 minutes and adequate muscle relaxation for 36 minutes (range 29 to 46 minutes).

Maintenance dose:

Same as adult dosing; see all comments.

DOSE ADJUSTMENTS

Reduce initial dose to 0.02 mg/kg in any condition that may result in a prolonged neuromuscular blockade (e.g., myasthenia gravis, myasthenic syndrome, carcinomatosis). Use a peripheral nerve stimulator to assess the level of neuromuscular block and to monitor dose requirements. See Drug/Lab Interactions. ■ Increased initial and maintenance doses may be required in burn patients. Duration of action may be shortened. ■ Time of onset may be slightly faster in patients with liver disease and slower in the elderly and patients with renal disease. Slower onset may require a delay of an additional minute before intubation. No clinically significant alteration in the recovery profile was identified. ■ Reduce maintenance dose by 30% to 40% in the presence of isoflurane or enflurane anesthesia. Larger reductions may be indicated in prolonged anesthesia. ■ Therapeutic hypothermia may prolong the duration of effect. Adjust doses accordingly.

DILUTION

IV bolus:

May be given undiluted.

Infusion:

Further dilute in NS, D5W, or D5NS to a 0.1 mg/mL or 0.4 mg/mL solution. Using the 2 mg/mL solution, 10 mg diluted in 95 mL yields 0.1 mg/mL; 40 mg diluted in 80 mL yields 0.4 mg/mL.

ICU infusion:

A 20-mL vial (10 mg/mL concentration) is available for use in ICU (200 mg/vial). 200 mg in 1,000 mL yields 0.2 mg/mL, in 500 mL yields 0.4 mg/mL.

Storage:

Refrigerate in carton before use; protect from light; do not freeze. Use within 21 days if at room temperature even if it was re-refrigerated. Most diluted solutions are stable refrigerated or at room temperature for 24 hours.

COMPATIBILITY

Manufacturer lists propofol and ketorolac as **incompatible.** Has an acid pH and may be **incompatible** with alkaline solutions having a pH greater than 8.5 (e.g., aminophylline, barbiturates, sodium bicarbonate).

Manufacturer lists alfentanil, droperidol, fentanyl, midazolam, and sufentanil as **compatible** but does not specify **additive** or **Y-site.**

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV bolus:

A single dose over 5 to 10 seconds.

Infusion for anesthesia adjunct or ICU:

Use of a microdrip (60 gtt/mL) or volume infusion pump required. Adjust rate to desired dose based on the following charts for 0.1 mg/mL and 0.4 mg/mL. For 0.2 mg/mL solution in ICU, multiply rates (mL/hr) of 0.1 mg/mL solution by 2 or divide rates (mL/hr) of 0.4 mg/mL solution in half.

Cisatracurium Infusion Rates for a Concentration of 0.1 mg/mL					
Patient Weight (kg)	**Drug Delivery Rate (mcg/kg/min)**				
	1	1.5	2	3	5
	Infusion Delivery Rate (mL/hr)				
10 kg	6 mL/hr	9 mL/hr	12 mL/hr	18 mL/hr	30 mL/hr
45 kg	27 mL/hr	41 mL/hr	54 mL/hr	81 mL/hr	135 mL/hr
70 kg	42 mL/hr	63 mL/hr	84 mL/hr	126 mL/hr	210 mL/hr
100 kg	60 mL/hr	90 mL/hr	120 mL/hr	180 mL/hr	300 mL/hr

Cisatracurium Infusion Rates for a Concentration of 0.4 mg/mL					
Patient Weight (kg)	**Drug Delivery Rate (mcg/kg/min)**				
	1	1.5	2	3	5
	Infusion Delivery Rate (mL/hr)				
10 kg	1.5 mL/hr	2.3 mL/hr	3 mL/hr	4.5 mL/hr	7.5 mL/hr
45 kg	6.8 mL/hr	10.1 mL/hr	13.5 mL/hr	20.3 mL/hr	33.8 mL/hr
70 kg	10.5 mL/hr	15.8 mL/hr	21 mL/hr	31.5 mL/hr	52.5 mL/hr
100 kg	15 mL/hr	22.5 mL/hr	30 mL/hr	45 mL/hr	75 mL/hr

ACTIONS

A nondepolarizing skeletal muscle relaxant with intermediate onset and duration of action. An isomer of atracurium with three times its potency at a mg-for-mg dose. In contrast to most of the other neuromuscular blocking agents, cisatracurium has no clinically significant effect on HR or BP with usual doses even in patients with serious cardiovascular disease, and it also does not produce a dose-related histamine release. Cisatracurium competitively binds to cholinergic receptors on the motor end-plate to antagonize the action of acetylcholine, resulting in a block of neuromuscular transmission. Onset of action is 2 to 3 minutes, with a peak effect at 3 to 5 minutes. Duration of effect is dose dependent. After a single 0.1 mg/kg dose, duration is 35 to 45 minutes. With balanced anesthesia, recovery begins in 20 to 35 minutes. 95% recovery is obtained in 64 minutes (range: 25 to 93 minutes). Metabolized by a process that mostly bypasses both the kidney and the liver. Forms specific metabolites (e.g., alcohol, laudanosine) that do not have neuromuscular blocking activity. Because of reduced dose requirements, laudanosine accumulation is lower than with atracurium, lowering the potential of seizures. Half-life is 22 to 29 minutes. Eliminated renally, primarily as metabolites.

INDICATIONS AND USES

Adjunctive to general anesthesia for inpatients and outpatients to facilitate endotracheal intubation and to relax skeletal muscles during surgery. ■ Relax skeletal muscles during mechanical ventilation in ICU.

CONTRAINDICATIONS

Known hypersensitivity to cisatracurium, other bis-benzylisoquinolinium compounds (e.g., atracurium), and benzyl alcohol (some preparations contain benzyl alcohol). ■ Products containing benzyl alcohol (e.g., the 10-mL multidose vial) are contraindicated in premature infants.

PRECAUTIONS

For IV use only. ■ ***Administered by or under the observation of an experienced clinician who is familiar with the drug's actions and any possible complications of use. Adequate facilities, emergency resuscitation drugs and equipment, oxygen, neuromuscular blocking antagonists (e.g., anticholinesterase agents [e.g., neostigmine]), and an anticholinergic agent (e.g., atropine) must always be available.*** ■ Cisatracurium has no known effect on consciousness, pain threshold, or cerebration. To avoid distress to the patient, neuromuscular block should not be induced before unconsciousness; see Monitor. ■ Not recommended for rapid sequence intubation; succinylcholine is usually the drug of choice. ■ Severe anaphylactic reactions have been reported with neuromuscular blocking agents; some have been fatal. Use caution in patients who have had an anaphylactic reaction to another neuromuscular blocking agent (depolarizing or nondepolarizing); cross-reactivity has occurred. ■ Myasthenia gravis and other neuromuscular diseases increase sensitivity to cisatracurium, potentiating neuromuscular blockade. ■ Burn patients may develop resistance to nondepolarizing neuromuscular blocking agents. The extent of altered response depends of the size of the burn and the time elapsed since the burn injury; see Dose Adjustments. ■ Patients with hemiparesis or paraparesis may also demonstrate resistance to nondepolarizing muscle relaxants in the affected limbs; see Monitor. ■ Acid-base and/or serum electrolyte abnormalities may potentiate or antagonize the action of neuromuscular blocking agents. ■ Did not trigger malignant hypertension (MH) in susceptible pigs at doses above those required for humans, but has not been studied in MH-susceptible humans. ■ Will not counteract the bradycardia produced by many anesthetic agents or vagal stimulation. ■ In patients with renal or hepatic disease, half-life of metabolites is longer, and concentrations may be higher with long-term administration.

Monitor:

This drug produces apnea. Controlled artificial ventilation with oxygen and close observation are required at all times. Maintain a patent airway. ■ Use a peripheral nerve stimulator to monitor drug effect, determine the need for additional doses, confirm recovery from neuromuscular block, and avoid overdose. To avoid inaccurate dosing in patients with hemiparesis or paraparesis, neuromuscular monitoring should be performed on a nonparetic limb. ■ Monitor vital signs and ECG continuously. ■ Has no analgesic properties or effect on consciousness. Use in conjunction with anesthesia, sedation, or analgesia as indicated. ■ Action potentiated by hypokalemia and some carcinomas. ■ Action may be potentiated or antagonized by dehydration, electrolyte imbalance, body temperature, or acid-base imbalance.

Patient Education:

Review allergies with health care provider. ■ Anaphylactic reactions have been reported.

Maternal/Child:

Category B: use in pregnancy only if clearly needed. Safety for use during labor and delivery not established. ■ Use caution during breast-feeding. ■ Safety for use in infants under 1 month of age not established. ■ 10 mL (2 mg/mL) multiple-dose vials contain benzyl alcohol; do not use in newborns. ■ In pediatric patients 2 to 12 years of age, onset is faster, duration shorter, and recovery faster than in adults. In infants 1 month to 23 months of age, onset is faster; however, duration and recovery are similar to adults. ■ Rare incidences of wheezing, laryngospasm, bronchospasm, rash, and itching have been reported in pediatric patients.

Elderly:

Safely administered even in patients with significant cardiac disease. ■ Response similar to that seen in younger adults; however, greater sensitivity of some older individuals cannot be ruled out. ■ Onset to complete neuromuscular block slightly slower; delay intubation until fully effective.

DRUG/LAB INTERACTIONS

Potentiated by **general anesthetics** (e.g., enflurane, isoflurane), **aminoglycosides, clindamycin, colistimethate, tetracyclines, muscle relaxants, diuretics, lithium, local anesthetics, magnesium sulfate, procainamide, quinidine, succinylcholine, and others**. May need to reduce initial or maintenance dose of cisatracurium; use with caution. ■ In long surgical procedures using enflurane or isoflurane anesthesia, less frequent maintenance dosing, lower maintenance doses, or reduced infusion rates of cisatracurium may be necessary; see Dose Adjustments. ■ Propofol has no effect on duration of action or on dosing requirements for cisatracurium. ■ Antagonized by **acetylcholine and anticholinesterases.** ■ Duration of neuromuscular block may be shorter and dose requirements may be higher during maintenance infusion in patients stabilized on **carbamazepine or phenytoin**. ■ Time to onset of maximum block is faster when **succinylcholine** is given before cisatracurium. Succinylcholine must show signs of wearing off before cisatracurium is given. Use caution.

SIDE EFFECTS

Bradycardia, bronchospasm, flushing, hypotension, and rash occurred in fewer than 1% of patients. Inadequate and prolonged neuromuscular block, muscle weakness, and myopathy have been reported. Rare reports of seizures with similar agents in ICU could be caused by accumulated laudanosine, other conditions, or medications. Excessive dosing or prolonged action may result in respiratory insufficiency or apnea. Airway closure may be caused by relaxation of epiglottis, pharynx, and tongue muscles. Hypersensitivity reactions have been reported.

ANTIDOTE

Side effects can be medical emergencies. Treat symptomatically. Maintain a patent airway and continuous controlled artificial ventilation and oxygenation until full recovery is ensured. The more profound the neuromuscular block, the longer it will take until recovery begins. Recovery from neuromuscular block must be confirmed by a peripheral nerve stimulator before anticholinesterase agents (e.g., neostigmine or edrophonium) can be given with an anticholinergic agent (e.g., atropine) to reverse the muscle relaxation. Neostigmine 0.04 to 0.07 mg/kg at 10% recovery in conjunction with atropine should be effective in 9 to 10 minutes. Edrophonium 1 mg/kg at 25% recovery in conjunction with atropine should be effective in 3 to 5 minutes. Confirm recovery by 5-second head lift and grip strength. Recovery may be inhibited by cachexia, carcinomatosis, debilitation, or the concomitant use of certain drugs; see Drug/Lab Interactions. The effects of hemofiltration, hemodialysis, and hemoperfusion on plasma levels of cisatracurium and its metabolites are unknown. Resuscitate as necessary.

CISPLATIN BBW

(sis-**PLAH**-tin)
CDDP
Antineoplastic (alkylating agent)
pH 3.5 to 4.5

USUAL DOSE

Pretreatment:

Verify nonpregnancy status. Baseline studies indicated; see Monitor.

Prehydration required; see Precautions and Monitor. See Dose Adjustments. May be given in combination with amifostine to reduce nephrotoxicity and neurotoxicity of cisplatin. See amifostine monograph. Administration as a 6- to 8-hour infusion with intravenous hydration and mannitol has been used to reduce nephrotoxicity. Doses greater than 100 mg/M^2 once every 3 to 4 weeks are rarely used.

Metastatic testicular tumors:

Used in combination with other approved chemotherapeutic agents. 20 mg/M^2 daily for 5 days per cycle.

Metastatic ovarian tumors:

75 to 100 mg/M^2 on Day 1 every 4 weeks. Used in combination with cyclophosphamide (Cytoxan) 600 mg/M^2 IV on Day 1 every 4 weeks. Another regimen (unlabeled in cisplatin prescribing information) uses paclitaxel 135 mg/M^2 (as a 24-hour infusion) followed by cisplatin 75 mg/M^2. Both agents are given once every 3 weeks for 6 courses. See paclitaxel monograph; premedication required. Used as a ***single agent,*** the dose of cisplatin is 100 mg/M^2 every 4 weeks.

First-line treatment of ovarian cancer (unlabeled in cisplatin prescribing information):

Given in combination with paclitaxel as follows: give paclitaxel 135 mg/M^2 as an infusion over 24 hours. Follow with cisplatin 75 mg/M^2 as an infusion over 6 to 8 hours. Repeat every 3 weeks. See paclitaxel monograph; premedication required. Other dose combinations and infusion times are being used.

Advanced bladder cancer:

50 to 70 mg/M^2 once every 3 to 4 weeks. 50 mg/M^2 is recommended once every 4 weeks for patients heavily pretreated with radiation or chemotherapy. Numerous other doses and combinations are used.

Non–small-cell lung cancer (unlabeled in cisplatin prescribing information):

Given in combination with gemcitabine as follows: gemcitabine 1,000 mg/M^2 as an infusion on Days 1, 8, and 15 of each 28-day cycle. Follow the gemcitabine infusion on Day 1 with cisplatin 100 mg/M^2. See gemcitabine monograph; other dosing schedules are in use. Another regimen uses a combination of paclitaxel and cisplatin as follows: paclitaxel 135 mg/M^2 as an infusion over 24 hours followed by cisplatin 75 mg/M^2 over 6 to 8 hours. Repeat every 3 weeks. See paclitaxel monograph; premedication required. Also used with docetaxel 75 mg/M^2 infused over 1 hour followed immediately by an infusion of cisplatin 75 mg/M^2 over 30 to 60 minutes. Repeat every 3 weeks. See docetaxel monograph; premedication required.

DOSE ADJUSTMENTS

All doses adjusted based on prior radiation therapy or chemotherapy. ■ Repeat doses may not be given unless SCr is below 1.5 mg/100 mL and/or BUN is below 25 mg/100 mL. Renal toxicity becomes more prolonged and severe with repeated courses. Renal function must return to normal before next dose is given. ■ Platelets should be 100,000/mm^3 and leukocytes 4,000/mm^3; verify auditory acuity as within normal limits. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see Elderly.

DILUTION

Specific techniques required; see **Precautions**.

Available in liquid form, 1 mg/mL. Withdraw desired dose. Immediately before use, manufacturer recommends diluting a single dose in 2 liters of D5½NS or D5⅓NS containing 37.5 Gm of mannitol. Do not use D5W. Will decompose if adequate chloride ion not available. Is also diluted in smaller amounts of NS (100 to 500 mL). Do not use needles or IV tubing with aluminum parts to administer; a precipitate will form, and potency will decrease. See Monitor for additional optional additives.

Storage:

Cisplatin remaining in multidose vial is stable at CRT for 28 days protected from light or

7 days under fluorescent light. Do not refrigerate. Protect from light if it will not be used within 6 hours.

COMPATIBILITY

Manufacturer states, "Do not use needles, IV sets, or equipment containing aluminum." Aluminum reacts with cisplatin, causing precipitate formation and loss of potency. A precipitate will form if reconstituted solutions are refrigerated.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer as a slow IV infusion; ***should not be given as a rapid IV injection.*** Rates vary based on protocol. Manufacturer suggests administering each 1 liter of infusion solution over 3 to 4 hours. Give total dose (2 liters) over 6 to 8 hours. Rate must be sufficient to maintain hydration and diuresis. Infusion times of 30 to 120 minutes are common, but infusion time has also been extended to 24 hours/dose. One source recommends a maximum rate not to exceed 1 mg/min. Too-rapid administration increases nephrotoxicity and ototoxicity.

ACTIONS

A heavy metal complex (platinum and chloride atoms). Has properties similar to alkylating agents and is cell-cycle nonspecific. Inhibits DNA synthesis by formation of DNA cross-links. Concentration is highest in liver, prostate, and kidney; somewhat lower in bladder, muscle, testicle, pancreas, and spleen. Heavily protein bound. Only one-fourth to one-half of the drug is excreted in the urine by the end of 5 days. Platinum may be present in tissues for as long as 180 days after the last administration. Secreted in breast milk.

INDICATIONS AND USES

Treatment of metastatic testicular tumors; used in combination therapy with other approved chemotherapy agents in patients who have already received appropriate surgical and/or radiotherapeutic procedures. ■ Treatment of metastatic ovarian tumors; used in combination therapy with other approved chemotherapy agents in patients who have already received appropriate surgical and/or radiotherapeutic procedures. ■ Used as a single agent as secondary treatment in patients with metastatic ovarian tumors refractory to standard chemotherapy who have not previously received cisplatin therapy. ■ Used as a single agent for treatment of patients with transitional cell bladder cancer that is no longer amenable to local treatment such as surgery and/or radiotherapy. ■ Is used in specific combinations with other chemotherapeutic drugs.

Unlabeled uses:

First-line therapy for treatment of advanced cancer of the ovary in combination with paclitaxel. ■ First-line treatment of patients with inoperable, locally advanced, or metastatic non–small-cell lung cancer (NSCLC) in combination with gemcitabine, paclitaxel, or docetaxel. ■ Treatment of cancers of the brain, adrenal cortex, breast, cervix, uterus, endometrium, head and neck, esophagus, lung, and liver; osteogenic sarcomas; and numerous other malignancies.

CONTRAINDICATIONS

Hypersensitivity to cisplatin or other platinum-containing compounds, myelosuppressed patients, pre-existing impaired renal function, or hearing deficit.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Adequate facilities and emergency resuscitation equipment and supplies must always be available. ■ Renal toxicity can be cumulative and may be severe. ■ Other major dose-related toxicities include myelosuppression, nausea, and vomiting. ■ Ototoxicity (tinnitus, loss of high-frequency hearing, and/or deafness) can be significant and may be more pronounced in pediatric patients. ■ Anaphylaxis has been reported and may occur within minutes of cisplatin administration. ■ Labeling changed to read, “Doses greater than 100 mg/M^2/cycle once every 3 to 4 weeks are rarely used.” This is an effort to eliminate serious errors resulting from confusion with carboplatin. Flip-off seal on vial now says, “Call Dr. if dose greater than 100 mg/M^2/cycle.” ■ Neuropathies may occur with higher doses, greater frequency of average doses, or prolonged therapy. Usually occur after prolonged therapy but have been reported after a single dose. If symptoms of neuropathy are observed, discontinue cisplatin. ■ See Elderly.

Monitor:

Obtain baseline CBC, SCr, BUN, CrCl and calcium, magnesium, potassium, and sodium levels. Repeat CBC weekly and other listed labs before each subsequent cycle. ■ Hydrate patient with 1 to 2 L of infusion fluid for 8 to 12 hours before cisplatin administration. Urine output should exceed 100 to 150 mL/hr. ■ Maintain adequate hydration and urine output of at least 100 to 200 mL/hr for 24 hours after each dose. ■ Nausea and vomiting are frequently severe and prolonged (up to a week). May begin within 1 to 4 hours of administration or may be delayed. Prophylactic administration of antiemetics recommended. Fosaprepitant (Emend), ondansetron (Zofran), metoclopramide (Reglan), or dexamethasone are effective in most patients. ■ Ototoxicity is cumulative; test hearing before administration and regularly during treatment. Ototoxicity increased in pediatric patients. ■ Monitor uric acid levels before and during treatment and maintain hydration. Allopurinol and alkalinization of urine may be indicated. ■ Monitor for anaphylactic-like reactions (e.g., bronchoconstriction, facial edema, hypotension, tachycardia). ■ Monitor liver function periodically. ■ Perform neurologic exams on a regular basis. Neuropathy may present as paresthesias, areflexia, and loss of proprioception and vibratory sensation. ■ Replace depleted electrolytes as necessary. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor infusion site carefully during infusion; local soft tissue toxicity has been reported with extravasation. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Effective birth control recommended. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy; can cause fetal harm. Has a mutagenic potential. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established. ■ Ototoxicity increased in pediatric patients. All pediatric patients should have audiometric monitoring performed before initiation of therapy, before each dose, and for several years after therapy.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ Response (e.g., effectiveness) is similar to younger adults, but length of survival may be shorter. ■ Incidence of myelosuppression (e.g., severe leukopenia, neutropenia, thrombocytopenia), infectious complications, nephrotoxicity, and peripheral neuropathy may be increased.

DRUG/LAB INTERACTIONS

Ototoxicity and nephrotoxicity are potentiated with other **ototoxic or nephrotoxic agents** (e.g., aminoglycosides and loop diuretics). Concurrent use not recommended. ■ Serum levels of **anticonvulsant agents** (e.g., phenytoin) may become subtherapeutic when used concurrently with cisplatin. Monitor anticonvulsant levels; increased doses may be indicated. ■ Bone marrow toxicity increased with **other antineoplastic agents and/or radiation therapy.** ■ Synergistic with **etoposide**; may be beneficial. ■ May affect renal excretion and increase toxicity of many drugs **(e.g., bleomycin, methotrexate).** ■ Response duration may be shortened with concurrent use of **pyridoxine (vitamin B_6) and altretamine.** ■ Do not administer **live virus vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Are frequent; can occur with the initial dose and will become more severe with succeeding doses. Dose-related and cumulative renal insufficiency, including renal failure, is the major dose-limiting toxicity (often noted during the second week following a dose). Acute leukemia, alopecia, anaphylaxis (facial edema, hypotension, tachycardia, and wheezing within minutes of administration), asthenia, cardiac abnormalities, dehydration, diarrhea, electrolyte disturbances (hypocalcemia, hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia), elevated serum amylase, hemolytic anemia, hepatotoxicity, hyperuricemia, malaise, myelosuppression, nausea and vomiting (acute or delayed), syndrome of inappropriate antidiuretic hormone secretion (SIADH), neurotoxicity (including peripheral neuropathy that may be reversible, leukoencephalopathy, and reversible posterior leukoencephalopathy syndrome [RPLS]), ocular toxicity (e.g., blurred vision, cerebral blindness, optic neuritis, papilledema), ototoxicity including tinnitus and hearing loss in the high-frequency range, peripheral neuropathy (may be irreversible), vascular toxicities (e.g., cerebral arteritis, CVA, MI, or thrombotic microangiopathy [hemolytic-uremic syndrome (HUS)]), and vestibular toxicity.

Overdose:

Deafness, intractable nausea and vomiting, kidney failure, liver failure, neuritis, ocular toxicity, significant myelosuppression, and death.

ANTIDOTE

Notify physician of all side effects. Cisplatin may have to be discontinued permanently or until recovery. Symptomatic and supportive treatment is indicated. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Pretreatment with amifostine may reduce nephrotoxic, neurotoxic, and hematologic effects. Treat anaphylaxis with epinephrine, corticosteroids, oxygen, and antihistamines. There is no specific antidote. Hemodialysis appears to have little effect on removing platinum from the body because of the rapid and high degree of protein binding.

CLADRIBINE BBW

(**KLAD**-rih-bean)
Leustatin
Antineoplastic (antimetabolite)
pH 5.5 to 8

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

In all situations, may be administered on an outpatient basis with an appropriate pump and a central venous line in place. Administer any subsequent course with extreme caution. Hematologic recovery must be considered.

Hairy cell leukemia:

0.09 mg/kg/day equally distributed as a continuous infusion over 24 hours. Repeat daily for 7 consecutive days.

Chronic lymphocytic leukemia and Waldenström’s macroglobulinemia (unlabeled):

0.1 mg/kg/day equally distributed as a continuous infusion over 24 hours for 7 consecutive days.

Acute myeloid leukemia and mantle cell lymphoma (unlabeled):

5 mg/M^2/day over 2 hours for 5 days.

DOSE ADJUSTMENTS

May be required with severe bone marrow impairment, with prior radiation or myelosuppressive agents. ■ May be required in severe renal insufficiency; effects of renal or hepatic impairment on excretion of cladribine not yet clarified for humans. ■ See Drug/Lab Interactions.

DILUTION

Specific techniques required; see Precautions.

Available in single-use 10-mL vials containing 10 mg (1 mg/mL). Contains no preservatives; aseptic technique imperative. May develop a precipitate at low temperatures. Warm naturally to room temperature and shake vigorously. Do not heat or microwave.

Inpatient continuous infusion:

Add the calculated daily dose of cladribine through a sterile 0.22-micron disposable hydrophilic syringe filter to an infusion bag containing 500 mL of NS.

Outpatient continuous infusion:

A total 7-day dose is added to a calculated amount of bacteriostatic NS to make a total volume of 100 mL. Add the calculated dose of cladribine (7 days × 0.09 mg/kg or 0.09 mL/kg) to the infusion reservoir through the sterile 0.22-micron disposable hydrophilic syringe filter, then add the calculated amount of bacteriostatic NS to the reservoir through the filter. Total volume in the reservoir should equal 100 mL. Specific equipment (i.e., a sterile medication reservoir and pump capable of delivering accurate minute amounts into a central venous line [presently using SIMS Deltec medication cassette with SIMS Deltec pump]) and a specific process including the use of a 0.22-micron syringe filter are required. Preparation of cassette usually done by pharmacist. Line of cassette remains clamped until attached to central venous line and pump is functional. See literature for details, and follow all specific instructions for medication pump.

Filters:

To minimize the risk of microbial contamination, a 0.22-micron hydrophilic syringe filter is required in the preparation of the outpatient continuous infusion.

Storage:

Protect from light. Refrigerate before reconstitution. Never refreeze. Discard any unused concentrate. ***500 mL dilution*** is stable for at least 24 hours at RT under normal fluorescent light; may be refrigerated for up to 8 hours after dilution. Immediate use preferred. ***100 mL dilution*** is stable in reservoir of medication cassette for 7 days if correctly diluted.

COMPATIBILITY

D5W will cause degradation of cladribine. Manufacturer states, “Adherence to the recommended diluents and infusion systems is advised.”

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Inpatient continuous infusion:

A single dose properly diluted evenly distributed as an infusion over 24 hours.

Outpatient continuous infusion:

Administered through a central venous line (very concentrated solution). Medication reservoir and pump required (presently using Pharmacia Deltec medication cassette and pump worn as a portable pack). Set rate for equal distribution of 100 mL over 7 days. Follow all specific instructions for pump.

ACTIONS

A chlorinated purine nucleoside analog and synthetic antineoplastic agent. Mechanism of action is not known, but it is believed to be cytotoxic by inhibiting both DNA synthesis and repair. Affects both dividing and resting cells. The 7-day course for hairy cell leukemia has resulted in complete response in a majority of patients with no evidence of persistent bone marrow disease. Crosses the blood-brain barrier. Average half-life is 4.2 to 9.2 hours. Specific methods of metabolism and routes of excretion are not known. Some drug does appear in urine.

INDICATIONS AND USES

Treatment of active hairy cell leukemia (HCL) as defined by clinically significant anemia, neutropenia, thrombocytopenia, or disease-related symptoms.

Unlabeled uses:

Treatment of acute myeloid leukemia, chronic lymphocytic leukemia, mantle cell lymphoma, and Waldenström’s macroglobulinemia.

CONTRAINDICATIONS

Hypersensitivity to cladribine or any of its components; neonates (7-day dilution contains benzyl alcohol).

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Anticipate severe suppression of bone marrow function, including neutropenia, anemia, and thrombocytopenia; usually reversible and appears to be dose dependent. ■ Myelosuppressive effects are most notable during the first month after therapy. ■

Serious, sometimes fatal, infections have been reported (e.g., respiratory tract infections, pneumonia, viral skin infections, sepsis). ■ Neurologic toxicity, including paraparesis and quadriparesis, has been reported. Usually occurs with higher doses but has been seen with standard dosing regimens. ■ Because of the possibility of increased toxicity, use caution in known or suspected renal or hepatic insufficiency, or any severe bone marrow impairment, or prior cytotoxic or radiation therapy. ■ Acute nephrotoxicity has been observed with high doses (4 to 9 times the recommended dose for HCL). Risk of toxicity increased when given concurrently with other nephrotoxic agents and/or therapies. ■ Rare cases of tumor lysis syndrome have been reported. ■ Appears to be no relationship between serum concentrations and ultimate clinical outcome. ■ Additional courses did not improve overall response. ■ Current studies suggest that overall response rate may be decreased in patients previously treated with splenectomy, deoxycoformycin (pentostatin), and in patients refractory to alpha-interferon. ■ May cause prolonged bone marrow hypocellularity; clinical significance not known.

Monitor:

Obtain baseline CBC with differential and platelets before therapy. May be repeated as indicated, but usually not required again until 7 or 8 days after treatment begins; then monitor as indicated for at least 4 to 8 weeks (anemia, neutropenia, thrombocytopenia, infection [bacterial, fungal, or viral], and bleeding are common and must be treated promptly). Monitoring schedule facilitates outpatient treatment; keep in close contact with patient. ■ Consider possibility of infection if fever occurs; appropriate lab tests, x-rays, and broad-spectrum antibiotics may be indicated, especially in a febrile neutropenic patient. ■ Monitor uric acid levels before and during treatment; maintain hydration; allopurinol may be indicated (preferred agent). ■ Monitor renal and hepatic function periodically. ■ Platelet count usually returns to normal in 12 days (may be delayed if severe baseline thrombocytopenia was present), absolute neutrophil count (ANC) usually returns to normal in 5 weeks, and hemoglobin in 8 weeks. All should be normal by 9 weeks. ■ Complete response is indicated by an absence of hairy cells in bone marrow and peripheral blood and normalization of peripheral blood parameters. Confirm response with bone marrow aspiration and biopsy between 9 weeks and 4 months. ■ Prophylactic antiemetics may improve patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). Avoid constipation and avoid alcohol and aspirin (risk of GI bleeding).

Patient Education:

Avoid pregnancy; consider birth control options and future fertility. ■ Report fever, bleeding, cough, edema, injection site reactions, malaise, mouth sores, rashes, shortness of breath, stomach pain, and tachycardia promptly. Maintain hydration. ■ Manufacturer supplies a patient education booklet; review thoroughly and discuss with physician and nurse. ■ Review all literature provided with pump to deliver outpatient dosing. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy; has potential to cause fetal harm. Has caused suppression of testicular cells in monkeys; effect on human fertility unknown. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established. Investigationally used in higher doses to treat relapsed acute leukemia. Dose-limiting toxicity occurred.

Elderly:

Geriatric-specific problems not encountered in studies to date. Consider age-related organ impairment.

DRUG/LAB INTERACTIONS

Increased toxicity with other **myelosuppressive agents** (e.g., methotrexate). ■ May raise concentration of blood uric acid; increased doses of **antigout agents** (e.g., allopurinol) may be indicated; **avoid uricosurics** (e.g., probenecid, sulfinpyrazone). ■ Do not administer **live attenuated vaccines** to patients receiving antineoplastic agents.

SIDE EFFECTS

Fever occurs first. Onset of thrombocytopenia begins in 7 to 10 days followed by anemia (severe) and neutropenia (severe). Fatigue, headache, injection site reactions, infection, nausea, and rash are common. Many other side effects may or may not be related to cladribine: abdominal pain, abnormal breath sounds, abnormal chest sounds, anorexia, arthralgia, asthenia, chills, constipation, cough, diaphoresis, diarrhea, dizziness, edema, epistaxis, erythema, insomnia, malaise, myalgia, pain, petechiae, pruritus, purpura, shortness of breath, tachycardia, trunk pain, weakness, vomiting.

Post-Marketing:

Most of these additional side effects occurred in patients who received multiple courses of cladribine and include altered level of consciousness, aplastic anemia, conjunctivitis, elevated bilirubin and transaminases, hemolytic anemia, hypereosinophilia, hypersensitivity, myelodysplastic syndrome, neurologic toxicity, opportunistic infections, pulmonary interstitial infiltrates (usually with an infectious etiology), renal impairment, Stevens-Johnson syndrome, toxic epidermal necrolysis, and tumor lysis syndrome.

Overdose:

Acute nephrotoxicity, irreversible neurologic toxicity (paraparesis/quadriparesis), severe bone marrow suppression (anemia, neutropenia, and thrombocytopenia).

ANTIDOTE

Keep physician informed of all side effects; many will be treated symptomatically as indicated. Platelet or RBC transfusions are frequently required to treat anemia or thrombocytopenia, especially during the first month. Filgrastim (Neupogen, Zarxio) or pegfilgrastim (Neulasta) may be used to increase neutrophil count, although recovery is usually spontaneous. Use specific antibiotics to combat infection. Discontinue cladribine if renal toxicity, neurotoxicity, or overdose occurs. No specific antidote for overdose. Supportive therapy as indicated will help sustain the patient in toxicity. Resuscitate if indicated.

CLEVIDIPINE BUTYRATE

(klev-**ID**-i-peen **BUE**-tih-rate)
Cleviprex
Calcium channel blocker
Antihypertensive
pH 6 to 8

USUAL DOSE

Must be individualized to achieve the desired BP reduction. Titrate to patient response and BP goal.

Initial dose:

1 to 2 mg/hr (2 to 4 mL/hr) as a continuous infusion.

Dose titration:

Initially, double the dose at 90-second intervals. As the BP approaches goal, increase the dose by less than doubling and lengthen the time between dose adjustments to every 5 to 10 minutes. In general, a 1- to 2-mg/hr increase in dose will produce an additional 2- to 4-mm Hg decrease in systolic pressure. The maximum dose used for most patients in studies was 16 mg/hr.

Maintenance dose:

The desired therapeutic response for most patients occurs at 4 to 6 mg/hr (8 to 12 mL/hr). Doses as high as 32 mg/hr (64 mL/hr) have been administered. Data are limited. Because of lipid-load restrictions, no more than 1,000 mL or an average of 21 mg/hr (42 mL/hr) is recommended per 24-hour period. In studies, most infusions were administered for less than 24 hours. There is little experience with infusions lasting more than 72 hours at any dose.

Transition to oral therapy:

Discontinue or titrate the infusion downward while establishing appropriate oral therapy. Consider the lag time of onset of oral agent’s effect. See Monitor.

DOSE ADJUSTMENTS

Lower-end initial doses may be indicated in the elderly. Consider the potential for decreased organ function and concomitant disease or drug therapy. ■ Patients with abnormal hepatic or renal function may receive the initial dose listed under Usual Dose.

DILUTION

Strict aseptic technique is imperative. Available as a single-dose, ready-to-use vial containing a 0.5-mg/mL phospholipid emulsion that can support microbial growth. Invert vial gently several times before use to ensure uniformity of emulsion.

Filter:

No data available from manufacturer.

Storage:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F) or store at 25° C (77° F) for up to 2 months. Vials stored at RT should not be returned to the refrigerator. Do not freeze. Protect from light until administration. Once vial is punctured, use within 4 hours and discard any unused portion, including that which is currently being infused.

COMPATIBILITY

Manufacturer states, "Should not be administered in the same line as other medications. Should not be diluted, but can be administered via a Y-tube or medication port with SWFI, NS, D5W, D5NS, D5LR, LR, and 10% amino acid."

RATE OF ADMINISTRATION

Administer as a continuous infusion as outlined in Usual Dose. Use of an infusion device required. May be given through a central or peripheral line.

ACTIONS

A dihydropyridine calcium channel blocker. Mediates the influx of calcium during depolarization in arterial smooth muscle. Reduces mean arterial BP by decreasing systemic vascular resistance in a dose-dependent manner. Does not reduce cardiac filling pressure (preload), confirming the lack of effect on venous capacitance vessels. Vasodilation and the resulting decrease in BP may produce a reflex increase in heart rate. Onset of effects begins within 2 to 4 minutes. Evidence of tolerance or hysteresis has not been observed in patients receiving infusions of up to 72 hours' duration. Full recovery of BP is achieved 5 to 15 minutes after the infusion is stopped. Rapidly distributed. Highly protein bound. Metabolized by hydrolysis in the blood and extravascular tissues, making its elimination unlikely to be affected by hepatic or renal dysfunction. Half-life is approximately 15 minutes. Excreted primarily in urine and, to a lesser extent, in feces.

INDICATIONS AND USES

Reduction of BP when oral therapy is not feasible or not desirable.

CONTRAINDICATIONS

Allergies to soybeans, soy products, eggs, or egg products. ■ Defective lipid metabolism such as pathologic hyperlipidemia, lipoid nephrosis, or acute pancreatitis if accompanied by hyperlipidemia. ■ Severe aortic stenosis (afterload reduction can be expected to reduce myocardial oxygen delivery).

PRECAUTIONS

For IV use only. ■ Strict aseptic technique required; see Dilution. ■ May produce systemic hypotension and reflex tachycardia. Dose reduction may be indicated. ■ Use caution in patients with lipid metabolism disorders. Contains approximately 0.2 Gm of lipid per mL. Lipid intake restrictions may be necessary in these patients. A reduction in the quantity of concurrently administered lipids (e.g., propofol, IV fat) may be necessary to compensate for the amount of lipid infused as part of the clevidipine formulation. See Usual Dose. ■ May produce a negative inotropic effect and exacerbate heart failure. ■ Rebound hypertension may occur in patients undergoing prolonged therapy; see Monitor. ■ Has not been studied for the treatment of hypertension associated with pheochromocytoma.

Monitor:

Monitor BP and HR during infusion and until vital signs are stable. ■ Rebound hypertension may occur in patients who receive a prolonged infusion and are not transitioned to other antihypertensive therapies. Monitor BP for at least 8 hours after the infusion is discontinued. ■ During transition to oral therapy, continue BP monitoring until patient is stabilized. ■ Monitor heart failure patients closely.

Patient Education:

Promptly report signs of a hypertensive emergency (e.g., neurologic symptoms, vision changes, evidence of CHF). ■ Continued follow-up and treatment of pre-existing hypertension required.

Maternal/Child:

Category C: use during pregnancy only if potential benefit justifies potential risk to the fetus. ■ Safety in labor and delivery not established. Other calcium channel blockers suppress uterine contractions in humans. ■ Safety for use in breast-feeding not established; effects unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Response similar to that seen in younger adults; however, greater sensitivity in the elderly cannot be ruled out. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Formal studies have not been conducted. ■ Does not have the potential for inducing or inhibiting the cytochrome P_{450} system. ■ Use of **beta-blockers** as treatment for clevidipine-induced reflex tachycardia is not recommended. Experience is limited. ■ If used concomitantly with **beta-blockers** and beta-blockers are to be discontinued, withdraw beta-blocker therapy gradually. Clevidipine will not protect against the effects of abrupt beta-blocker withdrawal.

SIDE EFFECTS

Acute renal failure, atrial fibrillation, cardiac arrest, dyspnea, flushing, headache, hypotension, myocardial infarction, nausea, peripheral edema, rebound hypertension, reflex tachycardia, syncope, and vomiting.

Post-Marketing:

Decreased oxygen saturation (possible pulmonary shunting), hypersensitivity reactions, increased blood triglycerides, ileus.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Reduce dose for systemic hypotension or reflex tachycardia. Discontinue for suspected overdose. Reduction in antihypertensive effects should be seen within 5 to 15 minutes. Monitor BP and support if needed. Resuscitate as necessary.

CLINDAMYCIN PHOSPHATE BBW

(klin-dah-**MY**-cin **FOS**-fayt)
Cleocin Phosphate
Antibacterial
Antiprotozoal (lincosamide)
pH 5.5 to 7

USUAL DOSE

Doses based on susceptibility of specific organisms; see literature.

Serious infections:

600 to 1,200 mg/24 hr in 2, 3, or 4 equally divided doses (300 to 600 mg every 12 hours, 200 to 400 mg every 8 hours, or 150 to 300 mg every 6 hours).

More severe infections:

1,200 to 2,700 mg/24 hr in 2, 3, or 4 equally divided doses (600 to 1,350 mg every 12 hours, 400 to 900 mg every 8 hours, or 300 to 675 mg every 6 hours).

Life-threatening infections:

Up to 4,800 mg/24 hr has been given.

Acute pelvic inflammatory disease (unlabeled):

900 mg every 8 hours. Used in combination with gentamicin. Continue both drugs for at least 24 hours after patient improves. Complete 14-day treatment program with oral doxycycline or clindamycin.

CNS toxoplasmosis in AIDS (unlabeled):

600 mg every 6 hours. Used in combination with pyrimethamine (Daraprim) and leucovorin.

Pneumocystis jiroveci pneumonia (unlabeled):

600 mg every 6 hours or 900 mg every 8 hours. Used in combination with primaquine.

Babesiosis (unlabeled):

1,200 to 2,400 mg/24 hr in 4 equally divided doses (300 to 600 mg every 6 hours). Continue for 7 to 10 days. Used in combination with quinine.

Prophylaxis of bacterial endocarditis:

600 mg IV or PO 30 minutes before procedure.

PEDIATRIC DOSE

Pediatric patients over 1 month to 16 years of age:

20 to 40 mg/kg of body weight/24 hr in 3 or 4 equally divided doses based on the seriousness of the infection (5 to 10 mg/kg every 6 hours or 6.66 to 13.3 mg/kg every 8 hours). Alternately 350 mg/M^2/24 hr may be used (87.5 mg/M^2 every 6 hours or 116.6 mg/M^2 every 8 hours). 450 mg/M^2/24 hr may be used for more serious infections if necessary (112.5 mg/M^2 every 6 hours or 150 mg/M^2 every 8 hours).

Prophylaxis of bacterial endocarditis:

20 mg/kg IV or PO 30 minutes before procedure. Do not exceed adult dose.

NEONATAL DOSE

See Maternal/Child.

Under 1 month of age, full term:

15 to 20 mg/kg/day in 3 to 4 equally divided doses (3.75 to 5 mg/kg every 6 hours or 5 to 6.7 mg/kg every 8 hours).

DOSE ADJUSTMENTS

Dose adjustments are not required in the presence of mild to moderate renal or hepatic disease and should not be required in severe disease; see Monitor.

DILUTION

Available prediluted in 300-, 600-, and 900-mg doses, in ADD-Vantage vials for use with ADD-Vantage infusion containers, as a 150 mg/mL solution in flip-top vials, in ready-to-use Galaxy bags, and in pharmacy bulk packages (for use only by the pharmacy). Dilute ADD-Vantage vials with 50 to 100 mL of D5W or NS. Doses prepared using the 150 mg/mL solutions are most commonly diluted in 50 to 100 mL of D5W, NS, or other **compatible** infusion solution. Concentration of clindamycin in diluent should not exceed 18 mg/mL. See chart on inside back cover or product insert for additional diluents. May be further diluted in larger amounts of **compatible** infusion solutions and given as a continuous infusion after the initial dose.

Storage:

Store vials at CRT before use. Administration as soon as possible after dilution is recommended. Stable at CRT for at least 24 hours in **compatible** infusion solutions. See manufacturer's literature for additional stability data if diluted solutions are kept at RT, refrigerated, or frozen. Frozen solutions should be thawed at room temperature and not refrozen.

COMPATIBILITY

Manufacturer lists as **compatible** for 24 hours at RT with IV solutions containing sodium chloride, glucose, calcium, or potassium and with solutions containing vitamin B complex in concentrations usually used clinically. Manufacturer states, "No **incompatibility** has been demonstrated with the antibiotics carbenicillin, cephalothin, gentamicin, kanamycin, or penicillin."

Manufacturer lists as **incompatible** with aminophylline, ampicillin, barbiturates, calcium gluconate, magnesium sulfate, phenytoin.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Should not be administered intravenously undiluted as a bolus. Severe hypotension and cardiac arrest can occur with too-rapid injection.

Intermittent infusion:

30 mg or fraction thereof over at least 1 minute (each 300 mg over a minimum of 10 minutes/1,200 mg over a minimum of 40 to 60 minutes). Do not give more than 1,200 mg in single 1-hour infusion.

Continuous infusion:

Administer initial dose at 10 (15 or 20) mg/min over 30 minutes (rapid infusion rate). Will result in serum levels above 4 (5 or 6) mcg/mL. To maintain these serum levels, continue infusion at 0.75 (1 or 1.25) mg/min.

ACTIONS

A semi-synthetic antibiotic that quickly converts to active clindamycin. Bacteriostatic with activity against gram-positive aerobes and anaerobes, as well as some gram-negative anaerobes. It inhibits bacterial protein synthesis by binding to the 50S subunit of the ribosome. Widely distributed in most body fluids and tissues. There is no clinically effective distribution to cerebrospinal fluid. Predominantly metabolized by cytochrome P_{450} CYP3A4. Half-life is approximately 3 hours. Excreted in urine and feces in small amounts. Crosses placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of serious infections caused by susceptible anaerobic bacteria. ■ Treatment of serious infections due to susceptible strains of streptococcal, pneumococcal, and staphylococcal bacteria in penicillin-allergic patients. ■ Conditions for which clindamycin is indicated include septicemia, lower respiratory tract infections (including pneumonia, empyema, and lung abscess), and skin and skin structure, gynecologic (including endometritis, nongonococcal tubo-ovarian abscess, pelvic cellulitis, and postsurgical vaginal cuff infection), intra-abdominal (including peritonitis and intra-abdominal abscess), and bone and joint infections (including acute hematogenous osteomyelitis).

Unlabeled uses:

Alternative to sulfonamides with pyrimethamine to treat CNS toxoplasmosis in AIDS patients. ■ Treat *Pneumocystis jiroveci* pneumonia in combination with primaquine. ■ Treatment of babesiosis. ■ Prophylaxis of bacterial endocarditis. ■ Treatment of acute pelvic inflammatory disease.

CONTRAINDICATIONS

Known hypersensitivity to clindamycin or lincomycin.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, clindamycin should be used to treat or prevent only those infections proven or strongly suspected to be caused by bacteria. ■ Sensitivity studies are indicated to determine susceptibility of the causative organism to clindamycin. ■ Cross-resistance is sometimes observed among lincosamides, macrolides, and streptogramin B. Macrolide-inducible resistance to clindamycin occurs in some isolates of macrolide-resistant bacteria. Macrolide-resistant isolates of staphylococci and beta-hemolytic streptococci should be screened for induction of clindamycin resistance. ■ Avoid prolonged use; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ Because its use has been associated with severe colitis, it should be reserved for serious infections in which less toxic antimicrobial agents are inappropriate. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with clindamycin. ■ Use caution with a history of GI, severe renal, or liver disease, and in patients with a history of asthma or significant allergies. ■ Severe hypersensitivity reactions, including severe skin reactions such as toxic epidermal necrolysis, drug reaction with eosinophilia and systemic symptoms (DRESS), and Stevens-Johnson syndrome (SJS), some with fatal outcomes, have been reported. ■ Serious anaphylactic reactions have been reported. ■ Certain infections may require incision and drainage or other indicated surgical procedures in addition to antibiotic therapy. ■ Not appropriate to treat meningitis.

Monitor:

Capable of causing severe, even fatal, colitis; observe for symptoms of diarrhea. ■ Periodic blood cell counts and liver and kidney studies are indicated in prolonged therapy. ■ Monitor liver enzymes periodically in patients with severe liver disease. ■ Monitor for S/S of hypersensitivity reactions, including severe skin and anaphylactic reactions.

Patient Education:

Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Do not treat diarrhea without notifying physician.

Maternal/Child:

In clinical trials with pregnant women, the systemic administration of clindamycin during the second or third trimesters has not been associated with an increased frequency of congenital abnormalities. Should be used during the first trimester only if clearly needed. ■ Has the potential to cause adverse effects on the GI flora of a breast-fed infant. Consider risk versus benefit and the possibility of alternate therapy. Monitor the infant for S/S of adverse reactions (diarrhea, candidiasis or, rarely, CDAD) if administered to a breast-feeding mother. ■ Some dosage forms contain benzyl alcohol, which has been associated with a fatal "gasping syndrome" in neonates. ■ Benzyl alcohol can cross the placenta. ■ Monitor organ system functions if used in pediatric patients. ■ In cases of beta-hemolytic streptococcal infections, treatment should be continued for at least 10 days.

Elderly:

CDAD may occur more frequently in elderly patients (over 60 years of age) and may be more severe. Monitor carefully for changes in bowel frequency; may not tolerate diarrhea well.

DRUG/LAB INTERACTIONS

May potentiate **neuromuscular blocking agents**. ■ May decrease **cyclosporine** levels. Monitor and adjust dose if necessary. ■ Clindamycin is predominantly metabolized by CYP3A4 and to a lesser extent by CYP3A5. **Inhibitors of CYP3A4 and CYP3A5** (e.g., protease inhibitors, azole antifungals) may increase clindamycin concentrations. Monitor for possible adverse reactions. **Inducers of CYP3A4 and CYP3A5** (e.g., rifampin) may reduce clindamycin concentrations, decreasing effectiveness.

SIDE EFFECTS

Abdominal pain, abnormal liver function tests, agranulocytosis, anaphylaxis, angioedema, azotemia, cardiac arrest, CDAD, diarrhea, drug reaction with eosinophilia and systemic symptoms (DRESS), eosinophilia (transient), exfoliative dermatitis, hypersensitivity reactions, hypotension, injection site reactions, jaundice, leukopenia, metallic taste, nausea, neutropenia (transient), oliguria, polyarthritis (rare), proteinuria, pruritus, pseudomembranous colitis, severe skin reactions (e.g., toxic epidermal necrolysis, acute generalized exanthematous pustulosis [AGEP], erythema multiforme), skin rashes, thrombophlebitis, urticaria, vaginitis, vomiting.

ANTIDOTE

Notify the physician of any side effects. Discontinue the drug if indicated (e.g., CDAD, diarrhea, hypersensitivity reactions, severe skin reaction), treat hypersensitivity reactions as indicated, and resuscitate as necessary. Mild cases of CDAD may respond to discontinuation of drug. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Hemodialysis or CAPD will not decrease blood levels in toxicity.

CLOFARABINE

(kloh-**FARE**-ah-bean)
Clolar
Antineoplastic (metabolic inhibitor)
pH 4.5 to 7.5

PEDIATRIC DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Premedication:

Consider prophylactic antiemetic medications. Consider use of prophylactic steroids (e.g., hydrocortisone 100 mg/M² on Days 1 through 3) to mitigate or prevent the development of systemic inflammatory response syndrome (SIRS) or capillary leak syndrome (e.g., hypotension, pulmonary edema, tachycardia, tachypnea). See Drug/Lab Interactions.

Clofarabine:

52 mg/M² as an infusion each day for 5 consecutive days. Dose is based on body surface area (BSA), which is calculated using the actual height and weight before the start of each cycle. Repeat every 2 to 6 weeks; see Dose Adjustments. Frequency is based on recovery or return to baseline organ function. Median time between cycles during clinical studies was 28 days (range 12 to 55 days).

DOSE ADJUSTMENTS

Administer subsequent cycles no sooner than 14 days from the starting day of the previous cycle provided the patient’s ANC is greater than or equal to 0.75×10^9/L. ■ Reduce dose by 50% in patients with a CrCl between 30 and 60 mL/min. Information is insufficient to make a dose recommendation in patients with a CrCl less than 30 mL/min or in patients on dialysis. ■ Reduce the dose of the next cycle by 25% in patients experiencing a Grade 4 neutropenia (ANC less than 0.5×10^9/L) that lasts 4 or more weeks. ■ Withhold clofarabine if a clinically significant infection develops. When the infection is clinically controlled, restart therapy at full dose. ■ Discontinue if hypotension develops at any time during the 5 days of administration. ■ Discontinue drug immediately if Grade 3 or higher increases in SCr, liver enzymes, or bilirubin occur; see Monitor and Antidote. May be restarted (generally with a 25% dose reduction) when the patient is stable and organ function has returned to baseline. ■ Discontinue drug immediately if S/S of SIRS or capillary leak syndrome occur; see

Monitor and Antidote. May be restarted (generally with a 25% dose reduction) when the patient is stable. ■ Withhold clofarabine if a Grade 3 noninfectious nonhematologic toxicity occurs (excluding transient elevations in serum transaminases and/or serum bilirubin and/or nausea and vomiting that is controlled by antiemetics). With resolution or a return to baseline, restart clofarabine at a 25% dose reduction. ■ Discontinue therapy if a Grade 4 noninfectious nonhematologic toxicity occurs.

DILUTION

Specific techniques required; see Precautions.

Available in single-use 20-mL vials containing 20 mg (1 mg/mL). Contains no preservatives; aseptic technique is imperative.
Calculate the exact number of vials needed to achieve the total dosing volume required.

$$\text{Total number of vials required} = \text{Total dose (mg)} \div 20 \text{ mg}$$

$$\text{Dosing volume (mL)} = \text{Total dose (mg)}$$

For example, a child with a body surface area (BSA) of 0.75 M^2 would need a dose of 39 mg of clofarabine (39 ÷ 20 mg = 1.95 vials, so 2 vials of clofarabine would be needed; 39 mg equals a dosing volume of 39 mL).

Withdraw the calculated dose from the vial(s). Using a 0.2-micron syringe filter, add the calculated dose to a sufficient volume of D5W or NS to provide a final concentration between 0.15 mg/mL and 0.4 mg/mL (e.g., 39 mg [39 mL in the example above] added to 100 mL of D5W or NS will provide a final concentration of approximately 0.28 mg/mL).

Filters:

Use of a 0.2-micron syringe filter is recommended for use during dilution in D5W or NS.

Storage:

Store unopened vials at CRT. Diluted solutions may be stored at CRT but must be used within 24 hours.

COMPATIBILITY

Manufacturer states, “To prevent drug **incompatibilities,** no other medications should be administered through the same IV line.”

RATE OF ADMINISTRATION

A single dose properly diluted and evenly distributed as an infusion over 2 hours.

ACTIONS

A purine nucleoside metabolic inhibitor. Acts by inhibiting DNA synthesis. Also disrupts the mitochondrial membrane, causing the release of mitochondrial proteins, cytochrome C, and apoptosis-inducing factor, which leads to cell death. Is cytotoxic to rapidly proliferating and quiescent cancer cell types in vitro. Results in a rapid reduction of peripheral leukemia cells. Metabolism in the liver is very limited. Pathways of nonhepatic elimination not known. Estimated half-life is 5.2 hours. Excreted primarily in the urine.

INDICATIONS AND USES

Treatment of pediatric patients 1 to 21 years of age with relapsed or refractory acute lymphoblastic leukemia (ALL) after treatment with at least two prior regimens. This indication is based on response rate. There are no trials verifying an improvement in disease-related symptoms or increased survival with clofarabine.

Unlabeled uses:

Treatment of other relapsed or refractory leukemias, including acute myelocytic leukemia (AML), myelodysplastic syndrome (MDS), and chronic myeloid leukemia in blast phase.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ At the initiation of treatment, most patients have hematologic impairment as a manifestation of the leukemia. Clofarabine causes myelosuppression, which may be severe and prolonged. Treatment may result in prolonged and severe neutropenia, including febrile neutropenia. Patients may be at an increased risk for infection, including severe and fatal sepsis and opportunistic infections. ■ Use with great caution in patients with impaired hepatic or renal function. ■ May develop tumor lysis syndrome, cytokine release syndrome, systemic inflammatory response syndrome, capillary leak syndrome, and organ dysfunction; deaths have been reported; see Monitor. ■ Serious and fatal hemorrhage, including cerebral, GI, and pulmonary hemorrhage, has occurred. Most cases were associated with thrombocytopenia; see Monitor. ■ Patients who have previously received a hematopoietic stem cell transplant (HSCT) are at higher risk for hepatotoxicity suggestive of veno-occlusive disease (VOD) following treatment with clofarabine (40 mg/M^2) used in combination with etoposide (VePesid 100 mg/M^2) and cyclophosphamide (Cytoxan 440 mg/M^2); has also been reported with monotherapy. ■ Severe and fatal hepatotoxic events, including hepatitis and hepatic failure, have been reported; see Monitor. ■ Renal toxicity, including Grade 3 or 4 elevated creatinine, acute renal failure, and hematuria, have been reported; see Monitor and Dose Adjustments. ■ Fatal and serious cases of enterocolitis (neutropenic colitis, cecitis, and *C. difficile* colitis) have been reported. Occurs more frequently within 30 days of treatment and in the setting of combination chemotherapy. May lead to necrosis, perforation, hemorrhage, or sepsis complications. ■ Serious and fatal skin reactions (Stevens-Johnson syndrome [SJS] and toxic epidermal necrolysis [TEN]) have been reported. ■ Safety and effectiveness in adults not established. In a Phase 1 study of adults with refractory and/or relapsed hematologic malignancies, the pediatric dose of 52 mg/M^2 was not tolerated.

Monitor:

Obtain baseline CBC with differential and platelets and serum electrolytes. Bone marrow suppression is expected. Appears to be dose-dependent and is usually reversible (with interruption of clofarabine treatment) but can be severe; monitor regularly and more frequently in patients who develop cytopenias. Monitoring of CBC and platelets is recommended daily during the 5 days of clofarabine administration, then 1 to 2 times weekly or as clinically indicated. ■ Obtain baseline renal and hepatic function studies (e.g., SCr, bilirubin, ALT, AST), and uric acid levels. Monitor renal and hepatic function closely during the 5 days of clofarabine administration. Monitor for S/S of hepatitis and hepatic failure. Discontinue drug immediately if Grade 3 or higher increases in SCr, liver enzymes, or bilirubin occur; see Antidote. ■ Monitor HR, BP, and respiratory status closely during infusion. Hypotension should be reported immediately; see Antidote. ■ Monitor for S/S of tumor lysis syndrome (e.g., hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia, metabolic acidosis, urate crystalluria, and renal failure). Adequate hydration and antihyperuricemics (e.g., allopurinol) are indicated to prevent and/or treat hyperuricemia due to tumor lysis syndrome. ■ Monitor for S/S of cytokine release syndrome (e.g., hypotension, pulmonary edema, tachycardia, tachypnea); may develop into systemic inflammatory response syndrome (SIRS)/capillary leak syndrome (rapid onset of respiratory distress, hypotension, pleural and pericardial effusion, and multiorgan failure). Close monitoring and early intervention may reduce risk; see Pediatric Dose and Antidote. To reduce the effects of tumor lysis and other adverse events (e.g., SIRS), the continuous administration of IV fluids throughout the 5 days of clofarabine treatment is recommended. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending the result of C/S in a febrile neutropenic patient. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor patients for S/S of enterocolitis and treat promptly. ■ Monitor for development of skin reactions.

Patient Education:

Avoid pregnancy; effective birth control recommended for men and women. Report a suspected pregnancy immediately. ■ Drink plenty of fluids and avoid dehydration that may be caused by diarrhea and vomiting; report promptly if significant. ■ Laboratory monitoring required. ■ Promptly report bleeding, decreased urine output, dizziness, fainting spells, infection, jaundice, light-headedness, rapid respiratory rate, or a rapid heart rate. ■ Review medications with pharmacist or physician. Avoid medications that may be hepatotoxic or nephrotoxic, including OTC or herbal medications. ■ Skin rash may occur; report promptly if significant. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: avoid pregnancy; may cause fetal harm. Also has dose-related effects on male reproductive organs in animals. ■ Discontinue breast-feeding.

Elderly:

Not indicated in this patient population.

DRUG/LAB INTERACTIONS

Clinical drug-drug interactions have not been studied; however, the following cautions should be considered. ■ Primarily excreted by the kidneys; minimize exposure to drugs with known renal toxicity during the 5 days of clofarabine administration (e.g., **aminoglycosides, amphotericin B, NSAIDs** [e.g., ibuprofen, naproxen], **rifampin**). Risk of renal toxicity may be increased. ■ The liver is a known target organ for toxicity; consider avoiding drugs known to induce hepatic toxicity (e.g., **amiodarone, NSAIDs** [e.g., ibuprofen, naproxen], **phenothiazines** [e.g., prochlorperazine], **zidovudine**). ■ Close monitoring is required with concomitant administration of medications affecting blood pressure or cardiac function (e.g., **diuretics** [furosemide], **calcium channel blockers** [diltiazem], **and other antihypertensives**). ■ Cytochrome P_{450} inhibitors (e.g., cimetidine, erythromycins, antifungal agents [e.g., itraconazole], ritonavir, verapamil) and cytochrome P_{450} inducers (e.g., carbamazepine, phenobarbital, phenytoin, rifampin) are unlikely to affect the metabolism of clofarabine. The effect on cytochrome P_{450} substrates has not been studied.

SIDE EFFECTS

Bone marrow suppression (e.g., anemia, leukopenia, neutropenia, thrombocytopenia) is anticipated, appears to be dose dependent, and is usually reversible. Anxiety, diarrhea, fatigue, febrile neutropenia, fever, flushing, headache, mucosal inflammation, nausea and vomiting, palmar-plantar erythrodysesthesia syndrome, pruritus, and rash occur most frequently. SIRS/capillary leak syndrome (e.g., rapid onset of respiratory distress, hypotension, pleural and pericardial effusion, and multiorgan failure) has occurred and can be fatal. Hepatotoxicity (elevated AST, ALT, bilirubin), renal toxicity (elevated SCr, acute renal failure), and veno-occlusive disease of the liver have occurred. Serious and fatal hemorrhage (cerebral, GI, and pulmonary), enterocolitis (neutropenic colitis, cecitis, and *C. difficile* colitis), and skin reactions (SJS and TEN) have been reported. Numerous additional side effects may occur and include abdominal pain, anorexia, arthralgia, back pain, cardiac toxicity (e.g., pericardial effusion, tachycardia), confusion, constipation, cough, depression, dermatitis, dizziness, dyspnea, edema, elevated creatinine, epistaxis, erythema, gingival bleeding, hematuria, hepatobiliary toxicity (e.g., elevated AST, ALT, bilirubin), hepatomegaly, hypertension, hypotension, infections (e.g., bacteremia, cellulitis, herpes simplex, oral candidiasis, pneumonia, sepsis, staphylococcal), injection site pain, irritability, jaundice, lethargy, myalgia, pain, petechiae, pleural effusion, renal toxicity, respiratory distress, rigors, somnolence, sore throat, transfusion reaction, tremor, weight loss.

Post-Marketing:

Bone marrow failure, GI hemorrhage (including fatalities), hepatic failure, hepatitis, hyponatremia, Stevens-Johnson syndrome, toxic epidermal necrolysis, and veno-occlusive disease.

ANTIDOTE

Keep physician informed of all side effects; most will be treated symptomatically as indicated. Discontinue if hypotension develops at any time during the 5 days of administration. Discontinue clofarabine immediately if early S/S of SIRS or capillary leak (e.g., hypotension) appear. Use of albumin, diuretics, and steroids may be indicated. May consider restarting (usually at a lower dose) after the patient is stabilized and organ function has returned to baseline. Discontinue clofarabine immediately if substantial increases in SCr, liver enzymes, or bilirubin occur. May be restarted (possibly at a lower dose) when the patient is stable and organ function has returned to baseline. Discontinue clofarabine for exfoliative or bullous rash or if SJS or TEN is suspected. Bone marrow suppression must be resolved before additional doses can be given. Administration of whole blood products (e.g., packed RBCs, platelets, or leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Use specific antibiotics to combat infection. No specific antidote for overdose. Supportive therapy as indicated will help sustain the patient in toxicity. Should a hypersensitivity reaction occur, treat with antihistamines, corticosteroids, epinephrine, and oxygen as indicated. Resuscitate if indicated.

COAGULATION FACTOR VIIa (RECOMBINANT) RTS

BBW

(ko-ag-yew-**LA**-shun **FAK**-ter 7a [re-**KOM**-be-nant])
NovoSeven RT
Antihemorrhagic
pH 5.5

USUAL DOSE

Hemophilia A or B Patients with Inhibitors

Bleeding episodes:

90 mcg/kg every 2 hours until hemostasis is achieved or until the treatment has been judged to be ineffective. Doses between 35 and 120 mcg/kg have been used successfully. Minimum effective dose has not been established. The dose and dosing interval may be adjusted based on the severity of the bleeding and the degree of homeostasis achieved. In clinical studies, a decision on outcome was reached for a majority of patients with joint or muscle bleeds within 8 doses, although more doses were required for severe bleeds. For severe bleeds, dosing should continue at 3- to 6-hour intervals after hemostasis is achieved to maintain the hemostatic plug. The appropriate duration of posthemostatic dosing has not been studied and should be minimized; see Precautions.

If a new bleeding episode or rebleeding occurs, return to 2-hour dosing intervals.

Surgical intervention:

90 mcg/kg immediately before the intervention. Repeat every 2 hours during intervention. ***For minor surgery,*** postsurgical dosing should be administered every 2 hours for 48 hours and then every 2 to 6 hours until healing has occurred. ***For major surgery,*** postsurgical dosing should be administered every 2 hours for 5 days and then every 4 hours until healing has occurred. Additional doses may be given if required.

Congenital Factor VII Deficiency Patients

Bleeding episodes and surgical intervention:

15 to 30 mcg/kg every 4 to 6 hours until hemostasis is achieved. Doses as low as 10 mcg/kg have been effective. Dose and dosing interval should be adjusted to each individual based on the severity of bleeding and the degree of hemostasis achieved. Minimal effective dose has not been determined.

Acquired Hemophilia

70 to 90 mcg/kg every 2 to 3 hours until hemostasis is achieved. Minimum effective dose has not been determined.

PEDIATRIC DOSE

See Usual Dose. Clinical studies were conducted with dosing determined according to body weight and not according to age. See Maternal/Child.

DOSE ADJUSTMENTS

Dose and administration interval may be adjusted based on the severity of the bleeding and the degree of hemostasis achieved. If patient develops intravascular coagulation or thrombosis, dosage should be reduced or treatment stopped; see Monitor.

DILUTION

NovoSeven RT is room temperature stable (RTS); aseptic technique is imperative. Available in packages that contain 1-, 2-, or 5-mg vials with a specified volume of histidine diluent. Select the appropriate vial package based on the calculated dose. Bring vial and diluent to RT. Do not exceed 37° C (98.6° F). Reconstitute powder with provided diluent, aiming the needle (20- to 26-gauge needle recommended) and the stream of diluent against the side of the vial. Do not inject the diluent directly on the powder. Do not use SWFI or other diluents. Gently swirl vial until powder is completely dissolved. Final concentration of reconstituted solution is 1 mg/mL (1,000 mcg/mL).

Storage:

Before reconstitution, refrigerate or store between 2° and 25° C (36° and 77° F). Avoid exposure to direct sunlight. Do not freeze. After reconstitution, store at RT or refrigerate. Should be used within 3 hours. Do not freeze reconstituted product or store in syringe. Discard unused product.

COMPATIBILITY

Manufacturer states, “Intended for IV injection only and should not be mixed with infusion solutions. Do not store reconstituted solution in syringes.” If line needs to be flushed before or after NovoSeven RT administration, use NS.

RATE OF ADMINISTRATION

A single dose as a slow IV injection over 2 to 5 minutes, depending on dose administered.

ACTIONS

A vitamin K–dependent glycoprotein structurally similar to human plasma–derived factor VIIa. Produced by recombinant DNA technology. Promotes hemostasis by activating the extrinsic pathway of the coagulation cascade. When complexed with tissue factor, can activate coagulation factor X to factor Xa, and coagulation factor IX to factor IXa. Factor Xa, in complex with other factors, then converts prothrombin to thrombin. This leads to the formation of a hemostatic plug by converting fibrinogen to fibrin. Half-life is 2.3 hours. Duration of action is 3 hours.

INDICATIONS AND USES

Treatment of bleeding episodes or prevention of bleeding in surgical interventions or invasive procedures in hemophilia A or B patients with inhibitors to factor VIII or factor IX and in patients with acquired hemophilia. ■ Treatment of bleeding episodes or prevention of bleeding in surgical interventions or invasive procedures in patients with congenital FVII deficiency.

CONTRAINDICATIONS

Manufacturer states, “None.” Use with caution in patients with known hypersensitivity to coagulation factor VIIa (recombinant), any of its components, and in patients with known hypersensitivity to mouse, hamster, or bovine proteins.

PRECAUTIONS

For intravenous bolus administration only. ■ Should be administered to patients only under the direct supervision of a physician experienced in the treatment of bleeding disorders. ■ Thrombotic events have been reported in clinical trials as well as through post-marketing surveillance following coagulation factor VIIa (recombinant) RTS use for each of the approved indications. Patients with disseminated intravascular coagulation (DIC), advanced atherosclerotic disease, crush injury, septicemia, or concomitant treatment with aPCCs/PCCs (activated or nonactivated prothrombin complex concentrates) may have an increased risk of developing thrombotic events due to circulating tissue factor or predisposing coagulopathy. Use caution in patients with an increased risk of thromboembolic complications. These include, but are not limited to, patients with a history of coronary artery disease (CAD), liver disease, DIC, or postoperative immobilization; elderly patients; and neonates. ■ Coagulation factor VIIa has been studied in placebo-controlled trials outside the approved indications to control bleeding in intracranial hemorrhage, advanced liver disease, trauma, cardiac surgery, spinal surgery, and other therapeutic areas. Safety and effectiveness have not been established in these settings, and the use is not approved by the FDA. Arterial and venous thrombotic and thromboembolic events have been reported during post-marketing surveillance. Studies have shown an increased risk of arterial thromboembolic adverse events (e.g., MI, myocardial ischemia, cerebral infarction, and cerebral ischemia) with coagulation factor VIIa when administered outside the current approved guidelines. ■ Biologic and clinical effects of prolonged elevated levels of factor VIIa have not been studied; therefore, the duration of posthemostatic dosing should be minimized, and patients should be appropriately monitored by a physician experienced in the treatment of hemophilia during this time period.

Monitor:

Evaluation of hemostasis should be used to determine the effectiveness of therapy and to provide a basis for modification of the treatment schedule; coagulation parameters do not necessarily correlate with or predict the effectiveness of therapy. Coagulation parameters (e.g., PT, aPTT, plasma FVII clotting activity [FVII:C]) may be used as an adjunct to the clinical evaluation of hemostasis in monitoring the effectiveness and treatment schedule, although these parameters have shown no direct correlation to achieving hemostasis. ■ Patients with factor VII deficiency should be monitored for PT and factor VII coagulant activity before and after treatment. If the factor VIIa activity fails to reach the expected level, if PT is not corrected, or if bleeding is not controlled after treatment with the recommended doses, antibody formation should be suspected and analysis for antibodies should be performed. ■ The normal factor VII plasma concentration is 0.5 mcg/mL. Factor VIIa levels of 15% to 25% (0.075 to 0.125 mcg/mL) are generally sufficient to achieve normal hemostasis. ■ Monitor patients for the development of signs or symptoms of activation of the coagulation system or thrombosis. When there is laboratory confirmation of intravascular coagulation or presence of clinical thrombosis, dosage should be reduced or the treatment stopped, depending on the patient’s symptoms; see Dose Adjustments.

Patient Education:

Discuss benefits versus risk of therapy and signs of hypersensitivity reactions including hives, urticaria, chest tightness, wheezing, hypotension, and anaphylaxis. ■ Signs of bleeding may be similar to signs of thrombosis and can include new-onset swelling and pain in the limbs or abdomen, new-onset chest pain, shortness of breath, loss of sensation or motor power, or altered consciousness or speech.

Maternal/Child:

Category C: safety for use during pregnancy not established. Use only if clearly indicated and benefit justifies potential risk to the fetus. ■ Discontinue breast-feeding. ■ Thrombotic events have been reported in women without a prior diagnosis of bleeding disorders who have received coagulation factor VIIa for uncontrolled postpartum hemorrhage. ■ A decision should be made whether to discontinue nursing or to discontinue the drug. ■ The safety and effectiveness have not been studied to determine if there are differences among various age-groups from infants to adolescents

(0 to 16 years of age); see Pediatric Dose.

Elderly:

Numbers in clinical studies insufficient to determine if the elderly respond differently than younger subjects.

DRUG/LAB INTERACTIONS

The risk of potential interaction between factor VIIa and coagulation factor concentrates has not been adequately evaluated. Simultaneous use of **activated prothrombin complex concentrates** (e.g., anti-inhibitor coagulant complex [Feiba]) **or prothrombin complex concentrates** (e.g., factor IX [AlphaNine SD, Benefix]) should be avoided.

SIDE EFFECTS

Generally well tolerated. The majority of patients reporting side effects received more than 12 doses. The most common side effects are arthralgia, edema, fever, headache, hemorrhage, hypertension, hypotension, injection site reaction, nausea, pain, rash, and vomiting. Most serious adverse reactions are thrombotic events; however, the risk in patients with hemophilia and inhibitors is considered to be low. Fatal and nonfatal thrombotic events have been reported when used for both labeled and off-label indications. Other side effects include arthrosis, bradycardia, coagulation disorder, decreased fibrinogen plasma, decreased prothrombin, decreased therapeutic response, DIC, hemarthrosis, hypersensitivity reactions, increased fibrinolysis, pneumonia, pruritus, purpura, renal function abnormalities, shock, subdural hematoma, thrombosis, urticaria.

Post-Marketing:

High D-dimer levels and consumptive coagulopathy; thromboembolic events, including myocardial ischemia and/or infarction, cerebral ischemia and/or infarction, thrombophlebitis, arterial thrombosis, deep vein thrombosis, and related pulmonary embolism; and isolated cases of hypersensitivity reactions (including anaphylaxis) have occurred following use in both labeled and unlabeled indications.

ANTIDOTE

Discontinue drug and notify physician of any major side effects. Treat hypersensitivity reactions as indicated. For thrombosis or DIC, anticoagulation with heparin may be indicated.

COAGULATION FACTOR X (HUMAN)

(ko-ag-yew-**LA**-shun **FAK**-ter X)
Coagadex
Antihemorrhagic

USUAL DOSE (International Units [IU])

Dose, frequency, and duration must be individualized based on the severity of the factor X deficiency, location and extent of bleeding, patient's clinical condition, and individual clinical response. Each vial is labeled with the actual factor X potency/content in International units (IU). The dose to achieve a desired in vivo peak increase in factor X level can be calculated with the following formula.

Dose (IU) = Body weight (kg) × Desired factor X rise (IU/dL) × 0.5

The desired factor X rise is the difference between the patient's plasma factor X level and the desired level. The dosing formula is based on the observed recovery of 2 IU/dL per IU/kg (i.e., for each 1 IU/kg of factor X administered, the circulating factor X level increases by approximately 2 IU/dL).

On-demand treatment and control of bleeding episodes:

25 IU/kg at the first sign of bleeding. Repeat every 24 hours until the bleed stops. Do not administer more than 60 IU/kg daily.

Perioperative management of bleeding:

Do not administer more than 60 IU/kg daily.

Presurgery:

Calculate the dose of coagulation factor X required to raise plasma factor X levels to 70 to 90 IU/dL using the following formula.

Required dose (IU) = Body weight (kg) × Desired factor X rise (IU/dL) × 0.5

Postsurgery:

Repeat dose as necessary to maintain plasma factor X levels at a minimum of 50 IU/dL until there is no longer a risk of bleeding due to surgery.

DOSE ADJUSTMENTS

Adjust dose and duration based on factor X levels, location and extent of bleeding, patient's clinical condition, and clinical response to therapy.

DILUTION (International Units [IU])

Supplied in single-use glass vials containing approximately 250 or 500 IU (approximately 100 IU/mL after reconstitution) of factor X activity, packaged with 2.5 or 5 mL of SWFI, respectively, and a Mix2Vial transfer device. The total number of IUs available is clearly marked on each vial. Record the batch number of each vial. Consult instructions for reconstitution and administration in the package insert. If stored in the refrigerator, warm to room temperature (25° C [77° F]) before reconstitution. If more than 1 vial is required, use a new Mix2Vial transfer set for each vial of drug. Solution from multiple vials can be pooled into a single syringe. Do not shake. Do not use if the reconstituted solution is cloudy or contains any particles. The reconstituted solution should be clear or a slightly pearl-like solution.

Filters:

Incorporated into the Mix2Vial.

Storage:

Store in refrigerator or at RT (2° to 30° C [36° to 86° F]) in original carton to protect from light until ready to use. Do not freeze. Do not use beyond the expiration date on the product vial. Should be used immediately but must be used within 1 hour of reconstitution.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose may be administered as an infusion at a rate of 10 mL/min up to a maximum rate of 20 mL/min; consider patient comfort. Reduce rate of administration or interrupt the infusion if a marked increase in pulse occurs.

ACTIONS

Coagulation factor X is a plasma-derived, purified concentrate of human coagulation factor X. It temporarily replaces the missing factor X needed for effective hemostasis. After conversion to its active form (factor Xa), it associates with factor Va to form the prothrombinase complex, which activates prothrombin to thrombin. Thrombin then acts on soluble fibrinogen and factor XIII to generate a cross-linked fibrin clot. Mean half-life is approximately 30.3 hours.

INDICATIONS AND USES

Treatment of adults and pediatric patients (12 years of age and above) with hereditary factor X deficiency for on-demand treatment and control of bleeding episodes and perioperative management of bleeding in patients with mild hereditary factor X deficiency.

Limitation of use:

Perioperative management of bleeding in major surgery in patients with moderate and severe hereditary factor X deficiency has not been studied.

CONTRAINDICATIONS

Life-threatening hypersensitivity reactions to coagulation factor X or any of the product components.

PRECAUTIONS

For IV use only. ■ Administered under the direction of a physician knowledgeable in the treatment of coagulation disorders in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Hypersensitivity reactions, including anaphylaxis, have occurred; see Monitor. ■

Manufactured from human plasma. Risk of transmitting infectious agents (e.g., HIV, hepatitis and, theoretically, Creutzfeldt-Jakob disease) has been greatly reduced by screening, testing, and manufacturing techniques. However, risk of transmission cannot be totally eliminated. Health care professionals should use caution during administration; may have risk of exposure to viral infection. ■ Contains trace human proteins other than factor X. ■ Neutralizing antibodies (inhibitors) to factor X may occur; see Monitor.

Monitor:

Monitor BP and pulse during infusion. If a marked increase in pulse occurs, either reduce rate of infusion or interrupt the infusion. ■ Throughout the infusion, monitor for S/S of a hypersensitivity reaction (e.g., angioedema, chest tightness, chills, fever, headache, hypotension, lethargy, nausea, pruritus, rash, restlessness, tachycardia, urticaria, wheezing). ■ Monitor plasma factor X activity by performing a validated test (e.g., one-stage clotting assay) to confirm that adequate factor X levels have been achieved and maintained. ■ In surgery patients, monitor postinfusion plasma factor X levels before and after surgery to ensure that hemostatic levels are obtained and maintained. ■ Monitor for the development of factor X inhibitors. Perform a Nijmegen-Bethesda inhibitor assay if expected factor X plasma levels are not attained or if bleeding is not controlled with the expected dose of coagulation factor X.

Patient Education:

Review manufacturer's medication guide. ■ Promptly report S/S of a hypersensitivity reaction (e.g., dizziness, hives, itching, rash, tightness of the chest, wheezing). ■ Report a lack of clinical response to therapy; may be a manifestation of an inhibitor. ■ Report symptoms of possibly transmitted viral infections immediately. Symptoms may include anorexia, arthralgias, fatigue, jaundice, low-grade fever, nausea, or vomiting. ■ If traveling, bring an adequate supply of medication based on current treatment regimen.

Maternal/Child:

Use during pregnancy or labor and delivery only if clearly needed. ■ Safety for use during breast-feeding not known; consider benefit versus risk. ■ Safety and effectiveness for use in pediatric patients under 12 years of age not established.

Elderly:

Numbers insufficient to determine differences in response between older and younger patients.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been performed. ■ Use with caution in patients who are receiving other plasma products that may contain factor X (e.g., fresh frozen plasma, prothrombin complex concentrates [e.g., Kcentra]). ■ Based on its mechanism of action, coagulation factor X is likely to be counteracted by direct and indirect factor Xa inhibitors (e.g., apixaban, edoxaban, rivaroxaban).

SIDE EFFECTS

The most common side effects observed are back pain, fatigue, infusion site erythema, and infusion site pain. Hypersensitivity reactions have occurred.

ANTIDOTE

Keep the physician informed of side effects. Slow or interrupt infusion for a marked increase in pulse rate or a mild hypersensitivity reaction. Discontinue the infusion immediately if a severe hypersensitivity reaction occurs. Treat hypersensitivity as necessary (e.g., antihistamines, epinephrine, corticosteroids). Resuscitate as necessary.

COAGULATION FACTOR Xa (RECOMBINANT), INACTIVATED-zhzo BBW

(ko-ag-yew-**LA**-shun **FAK**-ter Xa)
Andexxa
Antidote
pH 7.8

USUAL DOSE

There are two dosing regimens.

Coagulation Factor Xa (recombinant) Dosing Regimens		
Dose[a]	**Initial IV Bolus**	**Follow-on IV Infusion**
Low dose	400 mg at a target rate of 30 mg/min	4 mg/min for up to 120 minutes
High dose	800 mg at a target rate of 30 mg/min	8 mg/min for up to 120 minutes

[a]The safety and effectiveness of more than one dose have not been evaluated.

The recommended dosing regimen is based on the specific FXa inhibitor, dose of FXa inhibitor, and time since the patient's last dose of the FXa inhibitor as outlined in the following chart.

Coagulation Factor Xa (Recombinant) Dose Based on Rivaroxaban or Apixaban Dose			
FXa Inhibitor	**FXa Inhibitor Last Dose**	**Timing of FXa Inhibitor Last Dose Before Coagulation Factor Xa (Recombinant) Initiation**	
		<8 Hours or Unknown	**≥8 Hours**
Rivaroxaban	≤10 mg	Low dose	Low dose
Rivaroxaban	>10 mg/Unknown	High dose	
Apixaban	≤5 mg	Low dose	
Apixaban	>5 mg/Unknown	High dose	

DILUTION

Available as a lyophilized powder in single-use vials of 100 mg of coagulation factor Xa (recombinant), inactivated-zhzo. To reduce the total reconstitution time needed during preparation, reconstitute all required vials in succession. The low-dose regimen will require 4 vials for the bolus and 5 vials for the infusion. The high-dose regimen will require 8 vials for the bolus and 10 vials for the infusion.

IV bolus preparation:

Reconstitute each 100-mg vial with 10 mL of SWFI using a 10-mL syringe and a 20-gauge (or higher) needle. Direct the solution onto the inside wall of the vial to minimize foam (final concentration 10 mg/mL). Gently swirl each vial until completely dissolved. **Do not shake.** Typical dissolution time for each vial is approximately 3 minutes. If dissolution is incomplete, discard the vial and do not use the product. Using a 60-mL or larger syringe with a 20-gauge (or higher) needle, withdraw the reconstituted solution from each of the vials until the required dosing volume is achieved. Transfer the solution into an empty polyolefin or polyvinyl chloride IV bag with a volume of 250 mL or less.

Continuous IV infusion preparation:

Follow the same procedure outlined for the IV bolus preparation. Reconstitute the number of vials needed based on the dose regimen. More than one 40- to 60-mL syringe, or an equivalent 100-mL syringe, may be used for transfer of the reconstituted solution to the IV bag.

Filters:

Must be administered through an IV line containing a sterile 0.2- or 0.22-micron in-line polyethersulfone or equivalent low–protein-binding filter.

Storage:

Store unopened vials at 2° to 8° C (36° to 46° F). Do not freeze. Reconstituted solution in vials is stable at RT for up to 8 hours or may be stored for up to 24 hours at 2° to 8° C (36° to 46° F). Reconstituted solution in IV bags is stable at RT for up to 8 hours or may be stored for up to 16 hours at 2° to 8° C (36° to 46° F). Discard partially used vials.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administered through an IV line containing a sterile 0.2- or 0.22-micron in-line polyethersulfone or equivalent low–protein-binding filter.

IV bolus:

Administer at a target rate of 30 mg/min.

IV continuous infusion:

Within 2 minutes after the bolus dose, administer the continuous IV infusion as outlined in Usual Dose for up to 120 minutes.

ACTIONS

The active ingredient in coagulation factor Xa (recombinant), inactivated-zhzo is a genetically modified variant of human factor Xa. It exerts its procoagulant effect by binding and sequestering the FXa inhibitors rivaroxaban and apixaban. A second procoagulant effect is its ability to bind and inhibit the activity of tissue factor pathway inhibitor (TFPI). Inhibition of TFPI activity can increase tissue factor-initiated thrombin generation. In dose-ranging studies, dosing as a bolus followed by a 2-hour continuous infusion resulted in a rapid decrease in anti-FXa activity (within 2 minutes after the completion of the bolus administration) followed by reduced anti-FXa activity that was maintained throughout the duration of the continuous infusion. The anti-Xa activity returned to placebo levels approximately 2 hours after completion of a bolus or continuous infusion. TFPI activity in plasma was sustained for at least 22 hours following coagulation factor Xa (recombinant) administration. Half-life ranges from 5 to 7 hours.

INDICATIONS AND USES

Indicated for patients treated with rivaroxaban and apixaban when reversal of anticoagulation is needed due to life-threatening or uncontrolled bleeding.

This indication is approved under accelerated approval based on the change from baseline in anti-FXa activity in healthy volunteers. An improvement in hemostasis has not been established. Continued approval for this indication may be contingent on the results of studies to demonstrate an improvement in hemostasis in patients.

Limitation of use:

Coagulation factor Xa (recombinant) has not been shown to be effective for, and is not indicated for, the treatment of bleeding related to any FXa inhibitors other than apixaban and rivaroxaban.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV use only. ■ Treatment with coagulation factor Xa (recombinant) has been associated with serious and life-threatening adverse events, including arterial and venous thromboembolic events, ischemic events (including myocardial infarction and ischemic stroke), cardiac arrest, and sudden deaths. Thromboembolic events have been observed within 30 days after administration of coagulation factor Xa (recombinant). The median time to the first event was 6 days. ■ Patients being treated with FXa inhibitor therapy have underlying disease states that predispose them to thromboembolic events. Reversing FXa inhibitor therapy exposes patients to the thrombotic risk of their underlying disease. To reduce the risk of thrombosis, resume anticoagulant therapy as soon as medically appropriate following treatment with coagulation factor Xa (recombinant). ■ The safety of coagulation factor Xa (recombinant) has not been evaluated in patients who experienced thromboembolic events or disseminated intravascular coagulation within 2 weeks before the life-threatening bleeding event requiring treatment with coagulation factor Xa (recombinant). ■ Safety of coagulation factor Xa (recombinant) also has not been evaluated in patients who received prothrombin complex concentrates, recombinant factor VIIa, or whole blood products within 7 days before the bleeding event. ■ Re-elevation or incomplete reversal of anticoagulant activity can occur. In studies, there was a rapid and substantial decrease in anti-FXa activity corresponding to the coagulation factor Xa (recombinant) bolus that was sustained through the end of the continuous infusion. After the infusion, there was an increase in anti-FXa activity that peaked 4 hours after infusion. ■ As with all therapeutic proteins, there is a potential for immunogenicity.

Monitor:

Monitor for thromboembolic events and initiate anticoagulation when medically appropriate. ■ Monitor for symptoms and signs that precede cardiac arrest and provide treatment as needed. ■ Monitor for S/S of ischemic events. ■ Standard clinical assessments (e.g., VS, hemoglobin measurements, CT assessments relevant to the type of bleeding [e.g., GI, cerebral]) may be used to evaluate effective hemostasis. ■ An anti-Xa activity assay that is calibrated to each specific factor Xa inhibitor may be available at some facilities and can be used to rule out clinically significant serum concentrations and quantify the anticoagulant effect of the given anti-Xa inhibitor.

Patient Education:

Reversing FXa inhibitor therapy increases the risk of thromboembolic events. Arterial and venous thromboembolic events, ischemic events, cardiac events, and sudden death were observed within 30 days after administration of coagulation factor Xa (recombinant). Report S/S of thrombosis (e.g., limb or abdominal swelling and/or pain, chest pain or pressure, shortness of breath, loss of sensation or motor power, altered consciousness, vision, or speech).

Maternal/Child:

Safety for use during pregnancy, labor and delivery, and during breast-feeding not established; use with caution and only if clearly indicated. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or efficacy were observed between the elderly and younger patients, but greater sensitivity of some older individuals cannot be ruled out.

DRUG/LAB INTERACTIONS

There are no known significant interactions.

SIDE EFFECTS

The most common side effects observed were infusion-related reactions, pneumonia, and urinary tract infections. Infusion-related reactions included cough, dysgeusia, dyspnea, feeling hot, and flushing. Thromboembolic events reported after administration of coagulation factor Xa (recombinant) included acute myocardial infarction, acute respiratory failure, cardiac arrest, cardiac thrombus, cardiogenic shock, congestive heart failure, deep venous thrombosis, embolic stroke, iliac artery thrombosis, ischemic stroke, nonsustained ventricular tachycardia, pulmonary embolism, and sudden death. No thromboembolic events were observed in healthy volunteers who received FXa inhibitors and were treated with coagulation factor Xa (recombinant).

ANTIDOTE

Notify physician of any side effect and treat as appropriate.

COLISTIMETHATE SODIUM

(koh-lis-tih-**METH**-ayt **SO**-dee-um)
Coly-Mycin M
Antibacterial
pH 7 to 8

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor and Precautions.

Adult and pediatric dose:

Based on severity of the infection. Dosage expressed in terms of colistin base. Range is 2.5 to 5 mg/kg/24 hr of colistin base equally divided into 1-2 doses. Can be given via nebulization as 150 mg every 8 hours over 60 minutes. Do not exceed the maximum dose of 5 mg/kg/24 hr.

PEDIATRIC DOSE

See Usual Dose.

DOSE ADJUSTMENTS

In obese patients, base dose on ideal body weight. ■ Caution and lower-end dosing suggested in the elderly. Consider age-related impaired organ function and concomitant disease or drug therapy. ■ Dose reduction may alleviate neurologic adverse reactions. ■ Reduce dose or increase time interval in patients with impaired renal function based on the following chart.

Suggested Modification of Dosage Schedules of Colistimethate Sodium for Adults With Impaired Renal Function

	Normal	Mild	Moderate	Severe
CrCl (mL/min)	**≥80**	**50-79**	**30-49**	**10-29**
Dosage Schedule	2.5-5 mg/kg divided into 2 to 4 doses per day	2.5-3.8 mg/kg divided into 2 doses per day	2.5 mg/kg once daily or divided into 2 doses per day	1.5 mg/kg every 36 hours

Note: The suggested total daily dose is calculated from colistin base activity.

DILUTION

Reconstitute a 150-mg vial with 2 mL SWFI. Swirl gently to avoid frothing. Concentration equals 75 mg/mL colistin base. May be further diluted in a desired amount (e.g., 100 to 1,000 mL) of D5W, D5NS, D5/½NS, NS, D5/¼NS, or LR for infusion.

Filters:

No significant loss of drug potency noted with filtration through a 0.22-micron cellulose ester membrane filter.

Storage:

Store at CRT before use. Reconstituted solutions are stable for up to 7 days at RT or refrigerated. Freshly prepare fully diluted solutions and complete administration within 24 hours.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV over 30-60 minutes.

ACTIONS

A polypeptide antibiotic. A surface-active agent that penetrates into and disrupts the bacterial cell membrane. Has bactericidal activity against selected aerobic gram-negative organisms. Serum half-life is 2 to 3 hours. Excreted in urine. Crosses placental barrier.

INDICATIONS AND USES

Treatment of acute or chronic infections due to sensitive strains of gram-negative bacilli (e.g., *Enterobacter aerogenes*, *Escherichia coli*, *Klebsiella pneumoniae*, and *Pseudomonas aeruginosa*).

CONTRAINDICATIONS

Hypersensitivity to colistimethate or its components. ■ Not indicated for infections due to *Proteus* or *Neisseria*.

PRECAUTIONS

To reduce the development of drug-resistant bacteria and maintain its effectiveness, colistimethate sodium should be used only to treat those infections that are proven or strongly suspected to be caused by susceptible bacteria. ■ May cause nephrotoxicity, which is thought to be a dose-dependent effect; use caution in patients with impaired renal function, including the elderly; see Dose Adjustments. ■ Usual doses in patients with impaired renal function will lead to high serum levels, which may lead to acute renal insufficiency, renal shutdown, and neurotoxicity, including muscle weakness and apnea. ■ Avoid prolonged use of drug; superinfection caused by overgrowth of nonsusceptible organisms may result. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. ■ Has caused transient neurologic disturbances (e.g., circumoral paresthesia or numbness, tingling or formication [feeling of something crawling on the skin] of extremities, generalized pruritus, dizziness, vertigo, and slurring of speech).

Monitor:

Obtain baseline BUN and serum creatinine. ■ Monitor for diminishing urine output, rising BUN and SCr, and decreased CrCl as indicated during therapy; dose reduction may be required. Nephrotoxicity may be reversible with discontinuation of colistimethate. ■ Monitor for S/S of neuromuscular disturbances. ■ Motor coordination may be impaired; supervise ambulation. ■ See Drug/Lab Interactions.

Patient Education:

May cause dizziness and vertigo. Request assistance with ambulation and do not drive vehicles or use hazardous machinery while on therapy. ■ Promptly report sensations of numbness or tingling, generalized itching, severe dizziness or vertigo, and slurring of speech. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Category C: use during pregnancy only if the potential benefit justifies the potential risk to the fetus. ■ Use caution during breast-feeding; similar drugs (e.g., colistin sulfate) are secreted in breast milk. ■ Use caution and monitor pediatric patients closely. Side effects are similar to adults; however, neonates, infants, and children either cannot or may not report them.

Elderly:

Dose selection should be cautious; see Dose Adjustments and Precautions. ■ Differences in response compared to younger adults not identified. ■ Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Risk of respiratory paralysis and renal dysfunction is increased with **certain other antibiotics** (e.g., aminoglycosides). Concurrent use is not recommended; if necessary, use extreme caution. ***Apnea can occur.***

SIDE EFFECTS

Apnea; CDAD; decreased CrCl; decreased urine output; dizziness; fever; generalized itching, urticaria, and rash; GI upset; hypersensitivity reactions, including anaphylaxis; increased BUN and SCr; nephrotoxicity; paresthesia; respiratory distress; seizures; slurred speech; tingling of extremities and tongue; vertigo.

Overdose:

Neuromuscular blockade (e.g., ataxia, confusion, disorders of speech, dizziness, lethargy, nystagmus, paresthesia). Respiratory muscle paralysis may lead to apnea, respiratory arrest, and death. May also cause acute renal failure (e.g., decreased urine output and increases in BUN and SCr and decreased CrCl).

ANTIDOTE

Notify the physician of all side effects. Reduction in dose may alleviate symptoms. If symptoms of impaired renal function or overdose occur, discontinue the drug immediately and notify the physician. Nephrotoxicity may be reversible. Maintain an adequate airway and artificial ventilation as indicated. After drug plasma levels have fallen, colistimethate may be restarted in reduced doses if indicated. Treat allergic reactions symptomatically with antihistamines, pressor amines, and corticosteroids. Mild cases of CDAD may respond to discontinuation of colistimethate. Information not available on ability of hemodialysis or peritoneal dialysis to remove colistimethate in overdose. Resuscitate as indicated.

CONIVAPTAN HYDROCHLORIDE

(kon-ih-**VAP**-tan hy-droh-**KLOR**-eyed)
Vaprisol
Arginine vasopressin antagonist
pH 3.4 to 3.8

USUAL DOSE

Loading dose:

20 mg as an IV infusion over 30 minutes. Follow with 20 mg administered as a **continuous infusion** evenly distributed over 24 hours. May be administered for an additional 1 to 3 days as a continuous infusion of 20 mg/day. The total duration of infusion (after the loading dose) should not exceed 4 days.

DOSE ADJUSTMENTS

If the serum sodium does not rise at the desired rate, the dose may be titrated up to

40 mg as a continuous infusion over 24 hours. 40 mg is the maximum daily dose. ■ A reduced dose may be required if the patient experiences an undesirably rapid rate of rise of serum sodium; see Precautions. ■ If hyponatremia persists or recurs (after initial interruption of therapy) and the patient has no evidence of neurologic sequelae, conivaptan may be resumed at a reduced dose; see Monitor. ■ A reduced dose may also be required in patients who develop hypotension or hypovolemia; see Monitor. ■ No dose adjustment indicated in patients with mild hepatic impairment. ■ Reduced dose required in patients with moderate (Child-Pugh Class B) and severe (Child-Pugh Class C) hepatic impairment. Initiate with a loading dose of 10 mg. Follow with a continuous infusion of 10 mg over 24 hours for 2 days to a maximum of 4 days. If sodium is not rising at the desired rate, the conivaptan dose may be titrated up to 20 mg/day. ■ Use in patients with severe renal impairment (CrCl less than 30 mL/min) is not recommended; see Contraindications.

DILUTION

Available in a single-use, ready-to-use (RTU) plastic container containing 20 mg conivaptan in 100 mL D5W. If the RTU container is being administered as a 40-mg dose, administer two consecutive 20 mg/100 mL containers over 24 hours.

Storage:

Store at 25° C (77° F); however, brief exposure up to 40° C (104° F) does not adversely affect the product. Avoid excessive heat. Protect from light and freezing. Do not remove container from overwrap until ready to use. Overwrap is a moisture and light barrier.

COMPATIBILITY

Manufacturer states, “Should not be mixed or administered with lactated Ringer’s or furosemide. Should not be combined with any other product in the same intravenous line or bag. **Compatible** at the Y-site with NS at a flow rate for conivaptan of 4.2 mL/hr and NS at either 2.1 mL/hr or 6.3 mL/hr.”

RATE OF ADMINISTRATION

Loading dose:

A single dose equally distributed over 30 minutes as an infusion.

Continuous infusion:

A single dose equally distributed over 24 hours.

ACTIONS

A nonpeptide, dual arginine vasopressin (AVP) antagonist of V_{1A} and V_2 receptors. The level of AVP in the blood is critical for the regulation of water and electrolyte balance and is usually elevated in both euvolemic and hypervolemic hyponatremia (in euvolemic hyponatremia there is an increase in total body water, but the sodium content remains the same; in hypervolemic hyponatremia both sodium and water content in the body increase, but the water gain is greater). AVP excess is associated with hyponatremia without edema. The AVP effect is mediated through V_2 receptors that help maintain plasma osmolality within the normal range. Conivaptan blocks V_2 receptors in the renal collecting ducts, resulting in aquaresis (excretion of free water). This is generally accompanied by increased net fluid loss, increased urine output, and decreased urine osmolality within the normal range. Conivaptan is highly protein bound. It is metabolized in the liver by the cytochrome P_{450} isoenzyme, CYP3A. Its half-life is 5.3 to 8.1 hours, depending on dose. Primarily excreted in the feces and, to a lesser extent, in urine. Crosses the placenta in animals.

INDICATIONS AND USES

To raise serum sodium in the hospitalized patient with euvolemic and hypervolemic hyponatremia. Euvolemic hyponatremia may occur in the syndrome of inappropriate antidiuretic hormone secretion (SIADH, an inability of the body to excrete dilute urine) or in the setting of certain conditions, including hypothyroidism, adrenal insufficiency, and pulmonary disorders.

Limitations of use:

Conivaptan has not been shown to be effective for treatment of the S/S of heart failure. ■ It has not been established that raising serum sodium with conivaptan provides a symptomatic benefit.

CONTRAINDICATIONS

Patients with hypovolemic hyponatremia. ■ Coadministration with potent CYP3A inhibitors, such as clarithromycin, indinavir, itraconazole, ketoconazole, and ritonavir; see Drug Interactions. ■ Anuria (no benefit expected).

PRECAUTIONS

For IV use only. ■ Use only in hospitalized patients. ■ Safety for use in hypervolemic hyponatremic patients with underlying CHF has not been established. Should be used to raise sodium in these patients only after other treatment options have been considered. Incidence of adverse cardiac events may be increased. ■ An overly rapid increase in serum sodium concentration (more than 12 mEq/L/24 hr) may result in serious sequelae. Although not observed in clinical trials, osmotic demyelination syndrome has been reported following rapid correction of low serum sodium concentration. Osmotic demyelination results in dysarthria, mutism, dysphagia, lethargy, affective changes, spastic quadriparesis, seizures, coma, or death. Patients with severe malnutrition, alcoholism, or advanced liver disease may be at increased risk; use slower rates of correction; see Monitor. ■ Reduced doses required in patients with moderate or severe hepatic impairment; see Dose Adjustments. ■ May cause significant infusion site reaction; see Monitor.

Monitor:

Administer via a large vein. Monitor infusion site and rotate every 24 hours. ■ Monitor serum sodium concentration and neurologic status closely during therapy. If an overly rapid increase in serum sodium concentration occurs (greater than 12 mEq/L/24 hr), administration should be discontinued. If the sodium continues to rise, administration should not be resumed. If hyponatremia persists or recurs (after initial interruption of therapy) and the patient has no evidence of neurologic sequelae, conivaptan may be resumed at a reduced dose. ■ Monitor vital signs, urine output and osmolality, and volume status of patient. Discontinue therapy in patients who develop hypotension or hypovolemia. Once the patient is again euvolemic and is no longer hypotensive, therapy may be resumed at a reduced dose; see Dose Adjustments.

Patient Education:

Promptly report any burning at the infusion site or other side effects. ■ Request assistance for ambulation. ■ Review list of allergies and medications with physician or pharmacist.

Maternal/Child:

Use during pregnancy only if benefits justify risk to the fetus. Has been shown to cause fetal harm in animals. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients have not been studied.

Elderly:

Response similar to that seen in the general study population.

DRUG/LAB INTERACTIONS

A substrate of CYP3A. Concomitant use with **potent CYP3A4** inhibitors such as clarithromycin, indinavir, itraconazole, ketoconazole, and ritonavir increases conivaptan exposure and is contraindicated. ■ A potent inhibitor of CYP3A. Coadministration with **CYP3A4 substrates** (e.g., amlodipine, midazolam, and simvastatin) results in increased exposure of the other drug. Avoid concomitant use with drugs eliminated primarily by CYP3A-mediated metabolism. Subsequent treatment with CYP3A substrates may be initiated no sooner than 1 week after the infusion of conivaptan is complete. ■ May decrease clearance and increase serum concentration of **digoxin.** Monitor digoxin levels.

SIDE EFFECTS

The most common adverse reactions are infusion site reactions (e.g., erythema, pain, phlebitis), fever, headache, hypokalemia, and orthostatic hypotension. Other reactions that occurred in more than 2% of patients include anemia, atrial fibrillation, confusion, constipation, diarrhea, hypertension, hypomagnesemia, hyponatremia, hypotension, insomnia, nausea, peripheral edema, pharyngolaryngeal pain, pneumonia, pruritus, pyrexia, ST segment depression on ECG, thirst, urinary tract infection, and vomiting.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Discontinue therapy if there is an overly rapid increase in serum sodium concentration or if the patient experiences hypotension or hypovolemia. Discontinue therapy permanently if neurologic sequelae are present; see Precautions, Monitor, and Dose Adjustments.

Resuscitate as necessary.

CONJUGATED ESTROGENS BBW

(**KON**-jyou-**gay**-ted **ES**-troh-jens)
Premarin Intravenous
Hormone (estrogen)
Antihemorrhagic
pH 7.2 to 7.4

USUAL DOSE

Pretreatment:

See Patient Education and Maternal/Child.

Conjugated estrogens:

25 mg IV. May be repeated in 6 to 12 hours if indicated.

DILUTION

Reconstitute with 5 mL SWFI, directing the flow of diluent gently against the side of the vial. Agitate gently. Do not shake violently. Do not use if discolored or if precipitate is present. Dilution in an IV infusion is not recommended.

Storage:

Before reconstitution, store in refrigerator at 2° to 8° C (36° to 46° F). Use immediately after reconstitution.

COMPATIBILITY

Manufacturer lists as **incompatible** with ascorbic acid, protein hydrolysate, or any solution with an acid pH.

According to the manufacturer, infusion with other agents is not generally recommended. May be given at Y-tube if **compatible** solutions are infusing (NS, dextrose, and invert sugar solutions). According to one source, it is **compatible** at the **Y-site** with heparin, hydrocortisone sodium succinate, and potassium chloride (KCl).

RATE OF ADMINISTRATION

Administer slowly. Too-rapid injection may cause flushing. Must be given direct IV or through IV tubing close to needle site. Infusion solution must be **compatible.**

ACTIONS

A mixture of conjugated estrogens obtained exclusively from natural sources. Administration provides a rapid and temporary increase in estrogen levels. Acts at several points on the clotting cascade, enhancing coagulability of the blood, especially in the capillary beds. Promptly corrects bleeding due to estrogen deficiency. Widely distributed in the body. Metabolized primarily in the liver and excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Treatment of abnormal uterine bleeding due to hormonal imbalance in the absence of organic pathology. Indicated for short-term use only to provide a rapid and temporary increase in estrogen levels.

Unlabeled uses:

Uremic bleeding.

CONTRAINDICATIONS

Known, suspected, or history of breast cancer, active deep venous thrombosis, or pulmonary embolism. ■ A history of or active arterial thromboembolic disease (e.g., stroke, MI). ■ Known or suspected estrogen-dependent neoplasia, pregnancy, undiagnosed abnormal genital bleeding, liver dysfunction or disease. ■ Hypersensitivity to this product or its ingredients (e.g., known anaphylactic reaction and angioedema). ■ Known protein C, protein S, or antithrombin deficiency, or other known thrombophilic disorders. ■ Other specific contraindications for estrogens must be considered.

PRECAUTIONS

IV therapy with conjugated estrogens is indicated for short-term use. However, warnings and precautions associated with oral therapy should be considered (e.g., changes in vaginal bleeding, headache, hypersensitivity reactions, skin reactions, and many more); see Precautions and prescribing information. ■ Estrogen administration should be guided by clinical response rather than laboratory monitoring. Prescribe with or without progestins at the lowest effective doses and for the shortest duration consistent with treatment goals and risks for the individual woman. ■ Estrogens with or without progestins should not be used for the prevention of cardiovascular disease or dementia. ■ Even though bleeding is controlled, the etiology of the bleeding must be determined and definitive therapy instituted. ■ Hypersensitivity reactions, including anaphylaxis and angioedema, have been reported. Do not rechallenge patients who have had an anaphylactic reaction with or without angioedema. ■ May cause fluid retention. Use with caution in patients with cardiac or renal dysfunction. ■ Use with caution in asthma, diabetes, endometriosis, epilepsy, hepatic hemangiomas, hepatic or gallbladder disease, hypercalcemia or hypocalcemia, hypercholesterolemia, hypertension, hypoparathyroidism, migraines, obesity, porphyria, systemic lupus erythematosus, tobacco use, or venous thromboembolism (VTE); may exacerbate condition. ■ May lead to severe hypercalcemia in patients with breast cancer and bone metastases. ■ In women with pre-existing hypertriglyceridemia, estrogen therapy may be associated with further elevations of triglycerides, leading to pancreatitis. Consider discontinuation of treatment if pancreatitis occurs. ■ Consider the addition of progestin in women known to have residual endometriosis posthysterectomy. ■ May induce or exacerbate symptoms of angioedema, particularly in women with hereditary angioedema. ■

Retinal vascular thrombosis has been reported in patients receiving estrogen therapy. Discontinue therapy and obtain ophthalmologic exam if visual disturbances occur. ■ Patients dependent on thyroid hormone replacement therapy (e.g., levothyroxine [Synthroid]) who are also receiving estrogen may require dose adjustment of thyroid replacement medication. ■ Estrogen-alone therapy may increase the risk of deep venous thrombosis, stroke, endometrial cancer, and dementia in postmenopausal women. ■ Estrogen plus progestin therapy may increase the risk of deep venous thrombosis, MI, pulmonary embolism, stroke, invasive breast cancer, and dementia in postmenopausal women. ■ Follow immediately with oral estrogens as recommended for dysfunctional uterine bleeding.

Monitor:

Monitor VS; may cause a temporary BP elevation. ■ Due to the risk of endometrial cancer, adequate diagnostic measures, including directed or random endometrial sampling when indicated, should be undertaken to rule out malignancy in postmenopausal women with undiagnosed persistent or recurring abnormal genital bleeding. ■ Monitor thyroid function in order to maintain free thyroid hormone levels in an acceptable range. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, rash, urticaria).

Patient Education:

Review Patient Information leaflet. Review health history and disease states with physician before beginning treatment with conjugated estrogens. ■ Review possible side effects with physician and report any side effects promptly. ■ Use effective contraception if indicated.

Maternal/Child:

Avoid pregnancy. ■ Use caution during breast-feeding. Detectable amounts have been found in breast milk and may decrease quantity and quality of milk. ■ Safety for use in pediatric patients not established. Extended use may accelerate epiphyseal closure, which could result in short adult stature.

Elderly:

Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

May decrease effects of **oral antidiabetics.** ■ **Barbiturates** (e.g., phenobarbital), **carbamazepine, phenytoin, rifampin, and St. John's wort** increase metabolism and decrease serum levels and effects. ■ Plasma concentrations may be increased with coadministration of **clarithromycin, erythromycin, itraconazole, ketoconazole, ritonavir, and grapefruit juice**. ■ May decrease metabolism and increase serum levels of **cyclosporine.** May increase risk of cyclosporine toxicity. ■ Increased risk of hepatotoxicity with **other hepatotoxic agents** (e.g., dantrolene). ■ May increase **blood glucose** levels and **serum lipids.** ■ May reduce response to **metyrapone test.** ■ May alter numerous **coagulation tests, glucose tolerance, and thyroid and other protein-binding tests.**

SIDE EFFECTS

Rare when used as directed; flushing, nausea, vomiting. IV therapy with conjugated estrogens is indicated for short-term use. However, the numerous adverse reactions associated with oral therapy should be considered (e.g., changes in vaginal bleeding, headache, hypersensitivity reactions, skin reactions, and many more); see Precautions and prescribing information.

Post-Marketing:

Anaphylaxis within minutes to hours of infusion; angioedema involving the face, tongue, larynx, hands, and feet.

ANTIDOTE

No toxicity has been reported throughout years of clinical use. Discontinue if jaundice occurs. Discontinue immediately if DVT, MI, PE, stroke, or VTE occurs or is suspected. Discontinue if hypercalcemia occurs, and institute appropriate measures to reduce the serum calcium level. Permanently discontinue if examination reveals papilledema or retinal vascular lesions.

COPANLISIB

(koe-pan-**LIS**-ib)
Aliqopa
Kinase inhibitor
Antineoplastic

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies required; see Monitor.

Copanlisib:

60 mg administered as a 1-hour infusion on Days 1, 8, and 15 of a 28-day treatment cycle on an intermittent schedule (3 weeks on and one week off). Continue until disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Reduce dose to 45 mg in patients with moderate hepatic impairment (Child-Pugh B). No dose adjustment is needed in patients with mild hepatic impairment (total bilirubin equal to or less than 1 times the ULN and AST greater than ULN, or total bilirubin greater than 1 to 1.5 times the ULN and any AST).

Manage toxicities with dose reduction, treatment delay, or discontinuation of copanlisib as outlined in the following chart.

Copanlisib Dose Modification and Toxicity Management[a]		
Toxicities	**Adverse Reaction Grade**[b]	**Recommended Management**
Infections	Grade 3 or higher	Withhold copanlisib until resolution.
	Suspected *Pneumocystis jiroveci* pneumonia (PJP) infection of any grade	Withhold copanlisib. If confirmed, treat infection until resolution, then resume copanlisib at previous dose with concomitant PJP prophylaxis.
Hyperglycemia	Predose fasting blood glucose 160 mg/dL or more or random/nonfasting blood glucose 200 mg/dL or more	Withhold copanlisib until fasting glucose is 160 mg/dL or less or a random/nonfasting blood glucose is 200 mg/dL or less.
	Predose or postdose blood glucose 500 mg/dL or more	*First occurrence:* Withhold copanlisib until fasting blood glucose is 160 mg/dL or less or a random/nonfasting blood glucose is 200 mg/dL or less. Then reduce copanlisib dose from 60 mg to 45 mg and maintain.
		Subsequent occurrences: Withhold copanlisib as above, then reduce dose from 45 mg to 30 mg and maintain. If hyperglycemia is persistent at 30 mg, discontinue copanlisib.
Hypertension	Predose blood pressure (BP) 150/90 mm Hg or greater	Withhold copanlisib until BP is less than 150/90 mm Hg based on two consecutive BP measurements at least 15 minutes apart.
	Postdose BP 150/90 mm Hg or greater[c] (non–life threatening)	If antihypertensive treatment is not required, continue copanlisib at previous dose. If antihypertensive treatment is required, consider a dose reduction from 60 mg to 45 mg or from 45 mg to 30 mg. Discontinue copanlisib if BP remains uncontrolled (greater than 150/90 mm Hg) despite antihypertensive treatment.
	Postdose-elevated BP with life-threatening consequences	Discontinue copanlisib.
Noninfectious pneumonitis (NIP)	Grade 2	Withhold copanlisib and treat NIP. If NIP recovers to Grade 0 or 1, resume copanlisib at 45 mg. If Grade 2 NIP recurs, discontinue copanlisib.
	Grade 3 or higher	Discontinue copanlisib.
Neutropenia	Absolute neutrophil count (ANC) 500 to 1000 cells/mm^3	Maintain copanlisib dose. Monitor ANC at least weekly.
	ANC less than 500 cells/mm^3	Withhold copanlisib. Monitor ANC at least weekly until ANC is 500 cells/mm^3 or greater, then resume at previous dose. If ANC of 500 cells/mm^3 or less recurs, reduce dose to 45 mg.
Severe cutaneous reactions	Grade 3	Withhold copanlisib until toxicity is resolved, and reduce dose from 60 mg to 45 mg or from 45 mg to 30 mg.
	Life threatening	Discontinue copanlisib.

Thrombocytopenia	Platelet level less than 25,000 cells/mm^3	Withhold copanlisib and resume when platelet levels return to 75,000 cells/mm^3 or greater. If recovery occurs within 21 days, reduce dose from 60 mg to 45 mg or from 45 mg to 30 mg. If recovery does not occur within 21 days, discontinue copanlisib.
Other severe and non–life-threatening toxicities	Grade 3	Withhold copanlisib until toxicity is resolved, and reduce dose from 60 mg to 45 mg or from 45 mg to 30 mg.
Use with strong CYP3A inhibitors	See Drug/Lab Interactions	Reduce dose of copanlisib to 45 mg.

[a] Ensure a minimum of 7 days between any two consecutive infusions.

[b] National Cancer Institute Common Terminology Criteria for Adverse Events (CTCAE) v4.03.

[c] Both a systolic BP of less than 150 mm Hg and diastolic BP of less than 90 mm Hg are required.

DILUTION

Available as a lyophilized solid in a single-dose vial containing 60 mg of copanlisib. Reconstitute with 4.4 mL of NS. Gently shake vial for 30 seconds to dissolve the lyophilized solid. Allow to stand for 1 minute to let bubbles rise to the surface. Repeat the gentle shaking and settling process if any undissolved substance is still seen. Solution should be colorless to slightly yellow (concentration 15 mg/mL). Withdraw the desired dose (4 mL for 60 mg, 3 mL for 45 mg, or 2 mL for 30 mg) and further dilute in 100 mL of NS. Mix by inverting.

Filters:

Specific information not available.

Storage:

Refrigerate single-dose vial at 2° to 8° C (36° to 46° F). Use reconstituted and diluted solution immediately, or it may be refrigerated and used within 24 hours. After refrigeration, bring to room temperature before use. Avoid exposure of the diluted solution to direct sunlight. Discard any unused reconstituted or diluted solution.

COMPATIBILITY

Compatible only with NS. Manufacturer states, “Do not mix or inject with other drugs or other diluents.”

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 1 hour.

ACTIONS

An inhibitor of phosphatidylinositol-3-kinase (PI3K) with inhibitory activity predominantly against PI3K-α and PI3K-δ isoforms expressed in malignant B-cells. Copanlisib has been shown to induce tumor cell death by apoptosis and inhibition of proliferation of primary malignant B-cell lines and inhibition of several key cell-signaling pathways. Highly protein bound, primarily to albumin. Elimination half-life is 39.1 hours (range is 14.6 to 82.4 hours). Metabolism is 90% mediated by CYP3A and 10% mediated by CYP1A1. Excreted as unchanged compound and metabolites in feces and urine.

INDICATIONS AND USES

Treatment of adults with relapsed follicular lymphoma (FL) who have received at least two prior systemic therapies. Accelerated approval granted based on overall response rate. Continued approval may be contingent on verification and description of clinical benefit in a confirmatory trial.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV infusion only. ■ Serious, including fatal, infections have been reported. The most common serious infection is pneumonia. ■ Serious pneumocystis jiroveci pneumonia (PJP) has occurred. Consider PJP prophylaxis before initiating treatment with copanlisib in populations at risk. ■ Infusion-related hyperglycemia occurs. ■ Infusion-related hypertension has occurred. Serious infusion-related hypertensive events have been reported. ■ Noninfectious pneumonitis, neutropenia, and severe cutaneous reactions have been reported. ■ See Dose Adjustments for comprehensive information about serious reactions. ■ Pharmacokinetics of copanlisib in patients with severe hepatic impairment is unknown.

Monitor:

Monitor for S/S of infection. ■ Monitor blood glucose. Achieve optimal blood glucose control before starting each copanlisib infusion. Blood glucose levels typically peak 5 to 8 hours postinfusion and then decline to baseline levels in most patients. ■ Optimal BP control should be achieved before starting each copanlisib infusion. Monitor BP pre-infusion and postinfusion. BP has remained elevated for 6 to 8 hours after the start of the infusion, but the mean BP may start decreasing approximately 2 hours postinfusion. ■ A diagnostic examination is indicated in a patient with pulmonary symptoms (e.g., cough, dyspnea, hypoxia, or interstitial infiltrates on radiologic examination). May be treated with systemic corticosteroids. ■ Monitor blood counts at least weekly during treatment with copanlisib. ■ Monitor for cutaneous reactions (e.g., exfoliative dermatitis, exfoliative rash, maculopapular rash, pruritus). ■ See Dose Adjustments.

Patient Education:

See manufacturer’s patient information. ■ Review all medical conditions and medications (prescription and over-the-counter) with your health care provider. ■ Use of effective birth control is required during treatment with copanlisib and for at least 1 month after the last dose for females who are able to become pregnant and for males with female partners who are able to become pregnant. ■ Report a suspected pregnancy immediately. ■ Promptly report cough, difficulty breathing, fever, or shortness of breath. ■ Promptly report appearance of rash, redness, swelling, itching, or peeling of the skin. ■ Promptly report S/S of severe hypertension (e.g., dizziness, headache, fainting, and/or a pounding heart). ■ Report S/S of hyperglycemia (e.g., excessive hunger or thirst, frequent urination, headache). ■ Periodic laboratory monitoring is required.

Maternal/Child:

Based on findings in animals and on its mechanism of action, copanlisib can cause fetal harm. Conduct pregnancy testing before initiation of therapy. ■ Do not breast-feed during and for 1 month after treatment with copanlisib. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No clinically relevant differences in efficacy observed between elderly patients and younger patients. Patients 65 years of age and older may have a greater incidence of serious reactions.

DRUG/LAB INTERACTIONS

Concomitant use of copanlisib with **strong CYP3A inhibitors** increases copanlisib exposure (area under the curve [AUC]) and may increase the risk for toxicity. Examples of strong CYP3A inhibitors include boceprevir (Victrelis), clarithromycin (Biaxin), cobicistat (Tybost), conivaptan (Vaprisol), danoprevir/ritonavir, diltiazem (Cardizem), elvitegravir/ritonavir, grapefruit juice, idelalisib (Zydelig), indinavir/ritonavir, itraconazole (Sporanox), ketoconazole (Nizoral), lopinavir/ritonavir, nefazodone (Serzone), nelfinavir (Viracept), paritaprevir and ritonavir and (ombitasvir and/or dasabuvir), posaconazole (Noxafil), ritonavir (Norvir), saquinavir/ritonavir, tipranavir/ritonavir, troleandomycin (TAO), and voriconazole (Vfend). If concomitant use cannot be avoided, reduce copanlisib dose to 45 mg. ■ Avoid concomitant use of copanlisib with **strong CYP3A inducers;** may decrease AUC and C_{max}, decreasing effectiveness of copanlisib. Examples include carbamazepine (Tegretol), enzalutamide (Xtandi), mitotane (Lysodren), phenytoin (Dilantin), rifampin (Rifadin), and St. John's wort.

SIDE EFFECTS

Decreased general strength and energy, diarrhea, hyperglycemia, hypertension, leukopenia, lower respiratory tract infections, nausea, neutropenia, and thrombocytopenia are most common. Hyperglycemia, hypertension, infections, neutropenia, noninfectious pneumonitis, and severe cutaneous reactions are serious adverse reactions. Laboratory abnormalities include decreased hemoglobin, lymphocytes, neutrophils, platelets, and white blood cells; hyperglycemia; hypertriglyceridemia; hyperuricemia; hypophosphatemia; and increased serum lipase.

Oral pain, oropharyngeal erosion and ulcer, pneumonia (bacterial, fungal, pneumococcal, pneumocystis jiroveci, and viral), rash, stomatitis, and vomiting have also been reported.

ANTIDOTE

Keep physician informed of all side effects. May constitute a medical emergency or will be treated symptomatically as indicated. Dose will be withheld, reduced, or discontinued as indicated in Dose Adjustments. Discontinue copanlisib for postdose-elevated BP with life-threatening consequences, Grade 3 or higher noninfectious pneumonitis, and life-threatening severe cutaneous reactions. Administer appropriate treatment if an infusion reaction and/or a hypersensitivity reaction occur. Resuscitate if indicated.

CORTICORELIN OVINE TRIFLUTATE

(**KOR**-tih-koh-ren-len **OH**-vine **TRI**-ful-tayt)
Acthrel
Diagnostic agent
Hormone
(Adrenocorticotropic)

USUAL DOSE

Pretreatment:

See Precautions and Monitor.

1 mcg/kg as a single test dose. Produces maximal cortisol responses and significant ACTH responses. Doses above 1 mcg/kg are not recommended.

PEDIATRIC DOSE

Same as adult dose. Experience limited. No differences in response to the test have been reported.

DILUTION

Immediately before use, reconstitute each 100-mcg vial with 2 mL NS. Roll the vial gently to dissolve; avoid bubbles; do not shake. Contains 50 mcg/mL.

Storage:

Store unopened vials in refrigerator (2° to 8° C [36° to 46° F]) protected from light. The reconstituted solution is stable up to 8 hours when refrigerated. Discard unused solution.

COMPATIBILITY

Compatibility information not available from manufacturer. Consider specific use; consult pharmacist.

RATE OF ADMINISTRATION

To reduce incidence of side effects, a single dose over 30 to 60 seconds is preferred to a bolus injection.

ACTIONS

A synthetic peptide that is an analog of the naturally occurring human corticotropin releasing hormone. A potent stimulator of adrenocorticotropic hormone (ACTH) release from the anterior pituitary. ACTH stimulates cortisol production from the adrenal cortex. IV injection results in a rapid and sustained increase of plasma ACTH levels and a near-parallel increase of plasma cortisol. With usual dosage (1 mcg/kg) ACTH levels increase within minutes and peak in 15 to 60 minutes, and cortisol levels increase within approximately 10 minutes and peak in 30 to 120 minutes. Levels remain elevated for up to 2 hours.

INDICATIONS AND USES

To differentiate pituitary and ectopic production of ACTH in patients with ACTH-dependent Cushing's syndrome.

CONTRAINDICATIONS

Hypersensitivity to ovine corticorelin or any of its excipients.

PRECAUTIONS

Before testing, a diagnosis of hypercortisolism consistent with Cushing's disease not caused by autonomous adrenal hyperfunction should be established. Testing with corticorelin establishes the source of excessive ACTH secretions. ■ Administered by or under the direction of the physician specialist. Interpretation of test results requires knowledge of the clinical status of the patient, understanding of hypothalamic-pituitary-adrenal physiology, and familiarity with the normal hormonal ranges and standards used by the laboratory that performs the ACTH and cortisol assays. ■ Adverse effects, including transient tachycardia, hypotension, loss of consciousness, and asystole, have been associated with doses above 1 mcg/kg and bolus injections. ■ Hypersensitivity reactions have been reported. ■ Corticorelin does not affect insulin, plasma renin activity, prolactin, or growth hormone release. ■ AM and PM ACTH and cortisol levels differ and are usually higher in the morning; any subsequent tests required should be done at the same time of day as the original test. ■ False-negative response may occur in 5% to 10% of patients with Cushing's disease.

Monitor:

Obtain baseline vital signs. ■ Obtain instructions from the lab for handling blood samples; determination of ACTH and cortisol content can be directly impacted. ■ The corticorelin test requires a minimum of five blood samples to evaluate the status of the pituitary-adrenal axis in the differentiation of a pituitary source from an ectopic source of excessive ACTH secretion. ACTH and cortisol testing will be done from each sample. ■ Draw venous blood samples 15 minutes before and just before administration of corticorelin (these are averaged to obtain ACTH baseline). Administer corticorelin and draw venous blood samples 15, 30, and 60 minutes after administration. ■ Monitor the patient closely until all side effects have subsided. ■ Monitor for S/S of hypersensitivity reactions (e.g., angioedema; dyspnea; flushing of the face, neck, and upper chest; urticaria; wheezing).

Patient Education:

Report dizziness, feeling faint, or shortness of breath immediately.

Maternal/Child:

Category C: use only if clearly needed. ■ Safety not established; use caution if necessary during lactation (breast-feeding could be temporarily discontinued). ■ Limited experience in pediatric patients; no difference in response has been reported.

Elderly:

Specific information not available.

DRUG/LAB INTERACTIONS

Pretreatment with **dexamethasone** will inhibit or blunt the plasma ACTH response. ■ Use of **heparin** to maintain IV cannula patency during blood draws is not recommended. A possible interaction between corticorelin and heparin may have been responsible for a major hypotensive reaction that occurred in study patients after corticorelin administration.

SIDE EFFECTS

Hypersensitivity reactions have been reported and may include flushing of the face, neck, and upper chest; dyspnea; wheezing; urticaria; and angioedema involving the tongue, lip, and facial swelling. May cause an urge to take a deep breath.

Overdose:

Doses over 1 mcg/kg may cause dyspnea, hypotension, prolonged flushing, tachycardia, and a feeling of compression or tightness in the chest. Asystole and loss of consciousness have occurred.

ANTIDOTE

Notify the physician of any symptoms of overdose. Treat symptomatically. Emergency drugs (e.g., oxygen, epinephrine, diphenhydramine, atropine, and vasopressors [e.g., dopamine]) should be available. Resuscitate as necessary.

COSYNTROPIN

(koh-**SIN**-troh-pin)
Cortrosyn
Diagnostic agent (adrenocorticotropic)
pH 5.5 to 7.5

USUAL DOSE

Pretreatment:

See Drug/Lab Interactions. Baseline blood draw indicated.

Cosyntropin:

250 mcg (0.25 mg). The liquid formulation of cosyntropin is for IV use only. Cortrosyn may be used IV or IM.

PEDIATRIC DOSE

Pediatric patients over 2 years of age:

See Usual Dose.

Pediatric patients 2 years of age or less:

125 mcg (0.125 mg).

DILUTION

Available as a lyophilized powder or as a solution. Reconstitute powder with 1 mL NS. For IV use, both formulations should be diluted with 2 to 5 mL of NS. May be given directly IV after this initial dilution or further diluted in D5W or NS and given as an infusion (250 mcg in 250 mL equals 1 mcg/mL).

Storage:

Lyophilized powder: Store at CRT. ***Liquid formulation:*** Store at 2° to 8° C (36° to 46° F); protect from light and freezing. Discard any unused drug.

COMPATIBILITY

Manufacturer states, “Should not be added to blood or plasma; may be inactivated by enzymes.” Consider specific use.

RATE OF ADMINISTRATION

IV injection:

A single dose over 2 minutes.

Infusion:

A single dose at a rate of approximately 40 mcg/hr over 6 hours. Used to provide a greater stimulus to the adrenal gland. Infusions over 4 to 8 hours have been used.

ACTIONS

A synthetic subunit of adrenocorticotropic hormone (ACTH). Stimulates the adrenal cortex to secrete adrenocortical steroids (17-OH corticosteroids, 17-ketosteroids, and/or 17-ketogenic steroids). Does not increase cortisol secretion in patients with primary adrenocortical insufficiency. Peak plasma cortisol levels occur in 1 to 2 hours depending on formulation used.

INDICATIONS AND USES

Diagnostic aid for screening patients presumed to have adrenocortical insufficiency.

CONTRAINDICATIONS

Hypersensitivity to cosyntropin, synthetic ACTH, or any of the excipients.

PRECAUTIONS

Hypersensitivity reactions, including anaphylaxis, have been reported. Administer in a facility equipped to monitor the patient and respond to any medical emergency. ■ Cosyntropin is preferable to ACTH because it is less likely to cause hypersensitivity reactions. May be used in patients who have had a hypersensitivity reaction to natural ACTH. ■ Accuracy of diagnosis can be complicated by concomitant medications; see Drug/Lab Interactions. ■ Any condition that elevates or lowers cortisol binding globulin levels can increase or decrease plasma total cortisol levels, respectively. For example, cortisol binding globulin levels can be low in cirrhosis or nephrotic syndrome.

Monitor:

Collect a baseline blood sample of 6 to 7 mL before administration of cosyntropin. Collect a second blood sample 30 minutes and/or 60 minutes after administration; see prescribing information for sampling and blood storage requirements. Stimulated plasma cortisol levels of less than 18 to 20 mcg/dL at 30 or 60 minutes after cosyntropin administration are suggestive of adrenocortical insufficiency. ■ Measurement of cortisol binding globulin levels may be recommended to ensure accuracy of interpretation of plasma total cortisol levels. ■ Monitor for S/S of hypersensitivity reactions. ■ Check BP frequently; may cause elevated BP and salt and water retention. ■ See Drug/Lab Interactions and Precautions.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face).

Maternal/Child:

Category C: use during pregnancy only if benefits outweigh risks. ■ Use with caution during breast-feeding.

DRUG/LAB INTERACTIONS

Cortisone or hydrocortisone use may falsely elevate or, in a paradoxical response, lower plasma cortisol levels. **Spironolactone** use may also result in a falsely elevated cortisol level. Patients receiving cortisone, hydrocortisone, or spironolactone should omit their pretest doses on the day of testing. ■ Use of **synthetic glucocorticoid preparations** (oral, inhaled, or injectable) might suppress plasma cortisol levels. ■ Use of **estrogen-containing products** increases cortisol binding globulin levels, which can elevate plasma total cortisol levels. Discontinue estrogen-containing products 4 to 6 weeks before testing. Alternatively, concomitant measurement of cortisol binding globulin at the time of testing can be done; if cortisol binding globulin levels are elevated, plasma total cortisol levels are considered inaccurate. ■ May accentuate electrolyte loss associated with **diuretic therapy.**

SIDE EFFECTS

Bradycardia, hypertension, peripheral edema, rash, and tachycardia have been reported. Hypersensitivity reactions, including anaphylaxis (rare), have occurred.

ANTIDOTE

Notify the physician of any side effect. Keep epinephrine and diphenhydramine available to treat anaphylaxis. Resuscitate as necessary.

CRIZANLIZUMAB-tmca INJECTION

(**KRIZ**-an-**LIZ**-ue-mab in-**JEK**-shun)
Adakveo
Monoclonal antibody
Anti-P-selectin
pH 6

USUAL DOSE

5 mg/kg as an IV infusion over 30 minutes at Week 0, Week 2, and every 4 weeks thereafter. May be given with or without hydroxyurea.

PEDIATRIC DOSE

Pediatric patients 16 years of age and older:

See Usual Dose.

DOSE ADJUSTMENTS

If a dose is missed, administer crizanlizumab-tmca as soon as possible. If administered within 2 weeks after the missed dose, continue dosing according to the patient’s original schedule. If administered more than 2 weeks after the missed dose, continue dosing every 4 weeks thereafter.

DILUTION

Available in a single-dose vial as a clear to opalescent, colorless to slightly brownish-yellow solution containing 100 mg/10 mL (10 mg/mL). Calculate the dose (mg) and volume (mL) of solution required and the number of vials needed based on the patient's actual body weight. For example, in a 70-kg patient:

5 mg/kg × 70 kg = 350 mg

350 mg ÷ 10 mg/mL = 35 mL

35 mL ÷ 10 mL/vial = 3.5 vials; so 4 vials would be needed.

Bring the required number of vials to RT for a maximum of 4 hours before the start of preparation (piercing of the first vial). These vials are to be diluted to a final volume of 100 mL with NS or D5W. Infusion bags/containers must be made of either polyvinyl chloride (PVC), polyethylene (PE), or polypropylene (PP). Using a 100-mL infusion bag of NS or D5W, remove the volume of NS or D5W that is equal to the required volume of crizanlizumab-tmca (35 mL in the previous example). Then withdraw the required volume of crizanlizumab-tmca from the vial(s) and dilute by adding it to the infusion bag containing NS or D5W. The volume of crizanlizumab-tmca added to the infusion bag should not exceed 96 mL. Gently invert the infusion bag to mix the diluted solution. ***Do not shake.*** Do not use if particles are present in the solution.

Filters:

Use of a sterile, nonpyrogenic, 0.2-micron in-line filter is required.

Storage:

Immediate use of the diluted solution is preferred. If required, may be kept at RT up to 25° C (77° F) for no more than 4.5 hours from the piercing of the first vial to completion of the infusion, or may be refrigerated at 2° to 8° C (36° to 46° F) for no more than 24 hours from the piercing of the first vial to completion of the infusion. This includes storage of the diluted solution and the time to warm up to RT. Protect the diluted solution from light during storage under refrigeration. Discard partially used vials.

COMPATIBILITY

Manufacturer states, "Infusion bags/containers must be made of either polyvinyl chloride (PVC), polyethylene (PE), or polypropylene (PP). No **incompatibilities** have been observed with infusion sets composed of PVC, polyethylene (PE-lined PVC), polyurethane (PU), and in-line membranes composed of polyethersulfone (PES neutral and positively charged), positively charged polyamide (PA), and polysulphone (PSU)." Manufacturer also states, "Do not mix or coadminister with other drugs through the same IV line."

RATE OF ADMINISTRATION

A single dose distributed over 30 minutes through an IV line containing a sterile, nonpyrogenic, 0.2-micron in-line filter. Flush the IV line with at least 25 mL of NS or D5W after administration.

ACTIONS

Crizanlizumab-tmca is a selectin-blocker humanized IgG2 kappa monoclonal antibody that binds to P-selectin and blocks interactions with its ligands, including P-selectin glycoprotein ligand 1. Binding P-selectin on the surface of the activated endothelium and platelets blocks interactions between endothelial cells, platelets, red blood cells, and leukocytes. Expected to be metabolized into small peptides by catabolic pathways. Mean half-life about 7.6 days.

INDICATIONS AND USES

Reduce the frequency of vaso-occlusive crises (VOCs) in adults and pediatric patients 16 years of age and older with sickle cell disease.

CONTRAINDICATIONS

Manufacturer states, “ None.”

PRECAUTIONS

Administered by a health care professional in a facility with adequate diagnostic and treatment equipment to monitor the patient and respond to any medical emergency. ■ Infusion-related reactions have been reported (defined as occurring within 24 hours of infusion). ■ As with all therapeutic proteins, there is a potential for immunogenicity. ■ Interference with automated platelet counts (platelet clumping) has been observed; see Drug/Lab Interactions. ■ Effects on renal or hepatic impairment is unknown.

Monitor:

Monitor for S/S of an infusion-related reaction (e.g., chills, dizziness, fatigue, fever, nausea, pruritus, shortness of breath, sweating, vomiting, urticaria, or wheezing).

Patient Education:

Read the FDA-approved patient information. ■ Promptly report S/S of an infusion-related reaction (e.g., chills, dizziness, fatigue, nausea, pruritus, shortness of breath, sweating, urticaria, or wheezing). ■ Inform your health care provider of crizanlizumab-tmca use before any blood tests due to the potential interference with laboratory tests used to measure platelet counts. ■ Has the potential to cause fetal harm.

Maternal/Child:

Based on animal data, crizanlizumab-tmca has the potential to cause fetal harm when administered to a pregnant woman. Should be used during pregnancy only if the expected benefit to the patient justifies the potential risk to the fetus. ■ Women with sickle cell disease have an increased risk of adverse pregnancy outcomes for the mother and the fetus. Pregnant women are at greater risk for VOCs, pre-eclampsia, eclampsia, and maternal mortality. For the fetus, there is an increased risk for intrauterine growth restriction, preterm delivery, low birth weight, and perinatal mortality. ■ No data on the presence of crizanlizumab-tmca in human milk or on milk production. Maternal IgG is known to be present in human milk. The effects of local GI exposure and limited systemic exposure on the breast-fed child from crizanlizumab-tmca are unknown.

Consider risk versus benefit of breast-feeding. ■ Safety and effectiveness for use in sickle cell disease in pediatric patients 16 years of age and older has been established. ■ Safety and effectiveness for pediatric patients under 16 years of age has NOT been established.

Elderly:

Clinical studies did not include sufficient numbers of patients 65 years of age and older to determine whether they respond differently from younger patients.

DRUG/LAB INTERACTIONS

Interference with **automated platelet counts (platelet clumping)** has been observed, particularly when blood samples were collected in tubes containing ethylenediaminetetraacetic acid (EDTA), which may lead to unevaluable or falsely decreased platelet counts. Run blood samples within 4 hours of blood collection, or collect blood samples in tubes containing citrate. When needed, estimate platelet count via peripheral blood smear. ■ Hydroxyurea had no clinically meaningful effect on crizanlizumab-tmca pharmacokinetics.

SIDE EFFECTS

Most common adverse reactions are arthralgia, back pain, fever, and nausea. Infusion-related reactions have occurred. Other reported adverse reactions include abdominal pain, diarrhea, infusion site reactions, musculoskeletal chest pain, myalgia, oropharyngeal pain, pruritus, and vomiting.

ANTIDOTE

Notify physician of all side effects. Minor side effects may be treated symptomatically. Treat infusion reactions as appropriate based on severity.

CROTALIDAE IMMUNE F(ab’)$_2$ (EQUINE)

(kro-**TAL**-ih-day im **MYOUN** fab)
Anavip
Antivenin
pH not available

USUAL DOSE

Contact a regional poison control center for individual treatment advice.

Pretreatment:

Baseline studies required; see Monitor.

Adult and pediatric patients:

Administer as soon as possible after a rattlesnake bite in patients who develop any signs of envenomation (e.g., local injury, coagulation abnormality, or systemic signs of envenomation). The amount of antivenin required to treat a snakebite is highly variable and depends on venom burden, potency of the venom, and the time to health care presentation. Blood work required before administration; see Monitor.

Initial dose:

10 vials is the initial recommended dose. Monitor the patient for at least 60 minutes after completion of the infusion for any hypersensitivity reaction and to determine that local signs of envenomation are not progressing, systemic symptoms have resolved, and coagulation parameters have normalized or are trending toward normal; see Monitor.

Repeat doses:

Administer an additional 10 vials if needed to arrest the progressive symptoms. Observe patient following each infusion as previously outlined and in Monitor. May repeat every hour if needed. There is no known maximum dose.

Observation and late dosing:

Monitor patients in a health care setting for at least 18 hours following the initial control of signs and symptoms. Re-emerging symptoms, including coagulopathies, may be suppressed with an additional 4 vials as needed.

DOSE ADJUSTMENTS

Antivenin dose following a snakebite is expected to be the same in pediatric patients and adults; no dose adjustment for age is required.

DILUTION

Initial dose (10 vials), repeat doses (10 vials), observation and late dosing (4 vials):

Available as a sterile lyophilized preparation in a single-use vial. Reconstitute each vial with 10 mL of NS. Gently swirl to dissolve; should take less than 1 minute. Solution should be clear to yellow/green and opalescent. Do not use if discolored or turbid. Promptly combine the contents of the reconstituted vials (all 10 vials or all 4 vials) and further dilute with NS to a total volume of 250 mL. Fluid volumes may need to be adjusted for very small children or infants; consult a regional poison control center.

Filters:

Specific information not available.

Storage:

Store unopened vials at RT (up to 25° C [77° F]). Brief excursions are permitted up to 40° C (104° F). Do not freeze. Discard unused reconstituted and/or diluted product.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. Administration through a dedicated line is appropriate because of specific use and the potential for anaphylaxis.

RATE OF ADMINISTRATION

Administer as an infusion over 60 minutes. Infuse at 25 to 50 mL/hr for the first 10 minutes, carefully monitoring for any hypersensitivity reaction, including anaphylaxis. If no reactions occur, the infusion rate may be increased to deliver the full 250 mL/hr rate until completion. If there is any hypersensitivity reaction at any time, stop the infusion, treat accordingly, and reassess risk to benefit before continuing the infusion; see Antidote.

ACTIONS

A sterile, lyophilized, polyvalent preparation of equine immunoglobulin F(ab')$_2$ fragments manufactured from the plasma of horses immunized with the venom of *Bothrops asper* and *Crotalus durissus*. Manufacturing procedures contribute to the reduced risk of viral transmission. Contains venom-specific F(ab')$_2$ fragments of immunoglobulin G (IgG) that bind and neutralize venom toxins, facilitating redistribution away from target tissues and elimination from the body. Mean elimination half-life is approximately 133 hours.

INDICATIONS AND USES

An equine-derived antivenin for the management of adult and pediatric patients with North American rattlesnake envenomation.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

For IV use only. ■ Usually administered in the hospital by or under the direction of a physician knowledgeable in its use and in a facility equipped to monitor the patient and respond to any medical emergency. ■ May cause hypersensitivity reactions, including anaphylaxis. Patients with known allergies to horse protein are at particular risk for an anaphylactic reaction. ■ May cause delayed hypersensitivity reactions or serum sickness; see Monitor. ■ Made from equine (horse) plasma and may carry a risk of transmitting infectious agents (e.g., viruses). ■ Contains trace amounts of cresol. Localized reactions and generalized myalgias have been reported with the use of cresol as an injectable excipient.

Monitor:

Before initiating treatment, obtain a CBC, platelet count, PT, PTT, serum fibrinogen level, and routine serum chemistries. Repeat as indicated to gauge response to therapy and anticipate additional dosing. ■ Use supportive measures to treat other manifestations of rattlesnake envenomation, such as pain, swelling, hypotension, and wound infection. ■ Monitor for S/S of a hypersensitivity reaction (e.g., dyspnea, hypotension, rash, tightness of the chest, urticaria, wheezing) during the infusion and for at least 1 hour after completion of the infusion. ■ After completion of the infusion, monitor for at least 1 hour to determine that local signs of envenomation are not progressing (leading edge of local injury not progressing), systemic symptoms have resolved, and coagulation parameters have normalized or are trending toward normal. ■ Monitor for S/S of a delayed hypersensitivity reaction or serum sickness (e.g., arthralgia, fever, myalgia, pruritus, rash, urticarial rash) and treat appropriately if indicated.

Patient Education:

Immediately report any S/S of delayed hypersensitivity reactions or serum sickness (e.g., arthralgia, fever, myalgia, pruritus, rash, shortness of breath, or urticaria occurring after discharge). ■ Promptly report unusual bruising or bleeding (e.g., nosebleeds, excessive bleeding after toothbrushing or superficial injuries, blood in stools or urine, excessive menstrual bleeding, petechiae).

Maternal/Child:

Category C: use during pregnancy only if clearly needed. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients similar to adults.

Elderly:

Effectiveness in elderly adult similar to that in younger patients.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

The most common adverse reactions include arthralgia, erythema, headache, myalgia, nausea, pain in extremity, peripheral edema, pruritus, rash, and vomiting. In pediatric patients, fever, itching, nausea, and vomiting were most common. Hypersensitivity reactions, including anaphylaxis, have been reported. Anxiety, blisters, chills, dehydration, dyspnea, fever, insomnia, and thrombocytopenia have also occurred.

ANTIDOTE

Keep the physician informed of all side effects and the extent or progression of envenomation. Reduce the rate of administration if infusion-related reactions occur (e.g., low back pain, fever, nausea, wheezing). Monitor closely and discontinue the infusion if symptoms worsen or a hypersensitivity reaction occurs. Treat hypersensitivity reactions and/or anaphylaxis immediately with oxygen, epinephrine, antihistamines (e.g., IV diphenhydramine), corticosteroids, albuterol, vasopressors (e.g., dopamine), and ventilation equipment as indicated. Reassess risk to benefit before continuing the infusion. Recurrent coagulopathy may require rehospitalization and additional antivenin administration. Resuscitate as necessary.

CYCLOPHOSPHAMIDE

(sye-kloh-**FOS**-fah-myd)
Lyophilized Cytoxan, 🍁 Procytox
Antineoplastic (alkylating agent/ nitrogen mustard)
pH 3 to 7.5

USUAL DOSE

Pretreatment:

Verify pregnancy status.

Although effective alone in susceptible malignancies, cyclophosphamide is more frequently used concurrently or sequentially with other antineoplastic agents. **Doses may be expressed in mg/kg or mg/M^2.** During or immediately after administration, adequate amounts of fluid should be ingested or infused to force diuresis and thus reduce the risk of urinary toxicity. Cyclophosphamide should be administered in the morning; see Monitor.

Malignant diseases (adult and pediatric patients):

As a single agent: The initial dose may be 40 to 50 mg/kg of body weight, usually given in divided doses over 2 to 5 days. Alternate dosing schedules are 3 to 5 mg/kg twice weekly or 10 to 15 mg/kg every 7 to 10 days. Higher doses have been used with some protocols based on the condition being treated. Adequate hydration is indicated, and the use of mesna can be considered to attenuate or reduce the incidence of hemorrhagic cystitis. ***Combination protocols:*** Numerous combination therapies are in use. Has been used with bleomycin, bortezomib, carboplatin, cisplatin, dacarbazine, dexamethasone, docetaxel, doxorubicin, epirubicin, etoposide, fludarabine, fluorouracil, methotrexate, prednisone, procarbazine, rituximab, topotecan, vinblastine, and vincristine. See literature for various regimens.

Adjuvant treatment of operable node-positive breast cancer:

Treatment protocol includes cyclophosphamide, doxorubicin, and docetaxel. Administer cyclophosphamide 500 mg/M^2 and doxorubicin 50 mg/M^2. One hour later, give docetaxel 75 mg/M^2. Repeat every 3 weeks for 6 cycles. See docetaxel (Taxotere) and doxorubicin (Adriamycin) monographs.

PEDIATRIC DOSE

Malignant diseases:

See Usual Dose.

DOSE ADJUSTMENTS

Dosages must be adjusted based on antitumor activity and/or leukopenia. Total leukocyte count is a good, objective guide for regulating dosage. Withhold therapy in patients with neutrophils less than or equal to 1,500/mm^3 and platelets less than 50,000/mm^3. ■ When used as a component of a multidrug regimen, it may be necessary to reduce the dose of cyclophosphamide as well as the doses of the other drugs. ■ Dosing should be cautious in the elderly. Lower-end initial doses may be indicated. Consider decrease in cardiac, hepatic, and renal function; concomitant disease; or other drug therapy; see Elderly.

DILUTION

Specific techniques required; see Precautions.

Contains no preservatives; aseptic technique imperative. Each 100 mg must be diluted with 5 mL of NS or SWFI; yields 20 mg/mL (a 2% solution). Shake solution gently and allow to stand until clear. A 2% solution reconstituted with NS may be injected directly or further diluted to a minimum concentration of 0.2% (2 mg/mL) for infusion. A 2% solution reconstituted with SWFI is hypotonic and should not be injected directly. It ***must*** be further diluted to a minimum concentration of 0.2% (2 mg/mL). D5W, ½NS, and D5NS are **compatible** diluents. Do not use heat to facilitate dilution. See Monitor.

Filters:

May be filtered through available micron sizes of cellulose ester membrane filters.

Storage:

Store unopened vials at or below 25° C (77° F). Cyclophosphamide that is reconstituted in SWFI must be used immediately. Do not store. If reconstituted in NS or further diluted, it must be used within 24 hours when stored at RT. Solutions reconstituted in NS or further diluted in ½NS are stable up to 6 days if refrigerated. Solutions further diluted in D5W or D5NS are stable for 36 hours if refrigerated. Do not use cyclophosphamide vials if there are signs of melting (clear or yellowish viscous liquid or droplets).

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Rate may vary depending on protocol. May be given by IV push or as an intermittent or continuous infusion. Inject or infuse very slowly to reduce the likelihood of adverse reactions that may be administration rate–dependent (e.g., facial swelling, headache, nasal congestion, scalp burning). Duration of infusion should be appropriate for the volume to be infused.

ACTIONS

An alkylating agent of the nitrogen mustard group with antitumor activity; cell cycle phase nonspecific, but most effective in S phase. Cyclophosphamide is a prodrug that is activated by hepatic microsomal enzymes. It is thought to prevent cell division by cross-linking DNA strands and preventing DNA synthesis. Elimination half-life is 3 to 12 hours. Metabolized in the liver, it or its metabolites are excreted in the urine. Secreted in breast milk.

INDICATIONS AND USES

Although effective alone in susceptible malignancies, cyclophosphamide is more frequently used concurrently or sequentially with other antineoplastic agents. Cyclophosphamide has been used in the treatment of the following malignancies: malignant lymphomas (e.g., Hodgkin disease, lymphocytic lymphoma, mixed-cell–type lymphomas, histiocytic lymphoma, Burkitt's lymphoma), multiple myeloma, leukemias (e.g., chronic lymphocytic leukemia, chronic granulocytic leukemia, acute myelogenous and monocytic leukemia, acute lymphoblastic [stem cell] leukemia in children), mycosis fungoides, neuroblastoma, adenocarcinoma of the ovary, retinoblastoma, and carcinoma of the breast. ■ Adjuvant treatment of operable node-positive breast cancer in combination with doxorubicin and docetaxel. ■ Used orally to treat many other indications, including biopsy-proven nephrotic syndrome, in pediatric patients when disease fails to respond to primary therapy or when primary therapy causes intolerable side effects.

Limitation of use:

Safety and effectiveness for the treatment of nephrotic syndrome in adults or of other renal disease have not been established.

Unlabeled uses:

Ewing's sarcoma, granulomatosis with polyangiitis (GPA, Wegener's granulomatosis), lupus nephritis, non-Hodgkin lymphoma, severe rheumatologic conditions. ■ Transplant conditioning and many others; see literature.

CONTRAINDICATIONS

Hypersensitivity to cyclophosphamide, any of its metabolites, or to other components of the product. ■ Urinary outflow obstruction.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Myelosuppression (leukopenia, neutropenia, thrombocytopenia, and anemia), bone marrow failure, and severe immunosuppression may lead to serious and sometimes fatal infections. Sepsis and septic shock can occur. Latent infections (e.g., tuberculosis, viral hepatitis) can be reactivated. ■ Hemorrhagic cystitis, pyelitis, ureteritis, and hematuria have been reported. Urotoxicity can be fatal. ■ Exclude or correct any urinary tract obstructions before starting treatment; see Contraindications. ■ Use with caution, if at all, in patients with active urinary tract infections. ■ Myocarditis, myopericarditis, pericardial effusions including cardiac tamponade, and congestive heart failure have been reported and may be fatal. Supraventricular and ventricular arrhythmias (including severe QT prolongation) have been reported. Risk of cardiotoxicity may be increased with high doses, in the elderly, in patients with pre-existing cardiac disease, and in patients with previous radiation treatment to the cardiac region and/or previous or concomitant treatment with other cardiotoxic drugs (e.g., bleomycin, doxorubicin). ■ Pneumonitis, pulmonary fibrosis, pulmonary veno-occlusive disease, and other forms of pulmonary toxicity leading to respiratory failure have been reported during and after treatment with cyclophosphamide. Late-onset pneumonitis (greater than 6 months after the start of therapy) appears to be associated with increased mortality. Pneumonitis may develop years after treatment. ■ Development of secondary malignancies has been reported in patients treated with cyclophosphamide used alone or in association with other antineoplastic agents. May develop several years after treatment has been discontinued. ■ Risk of bladder cancer may be reduced by prevention of hemorrhagic cystitis. ■ Veno-occlusive liver disease (VOD) has been reported. Fatalities have occurred. A cytoreductive regimen in preparation for bone marrow transplantation that consists of cyclophosphamide in combination with whole-body irradiation, busulfan, or other agents has been identified as a major risk factor. VOD has also been reported to develop gradually in patients receiving long-term, low-dose, immunosuppressive doses of cyclophosphamide; in patients with pre-existing hepatic impairment; in patients who have received abdominal radiation; and in patients with low performance status. ■ Hyponatremia associated with increased total body water, acute water intoxication, and a syndrome that resembles syndrome of inappropriate antidiuretic hormone secretion (SIADH) has been reported. ■ Use caution in patients with impaired renal function. ■ Use with caution in patients with impaired hepatic function. Reduced conversion to active metabolite may cause decreased efficacy. ■ May interfere with normal wound healing. ■ Do not administer any live virus vaccine to patients receiving antineoplastic drugs. ■ Anaphylaxis resulting in death has been reported.

Monitor:

Monitor CBC and platelets and SCr frequently; see Dose Adjustments. ■ Check urinary sediment regularly for presence of erythrocytes and other signs of urotoxicity and/or nephrotoxicity. ■ Aggressive hydration with forced diuresis and frequent bladder emptying can reduce the frequency and severity of bladder toxicity. Mesna has been used to prevent severe bladder toxicity. ■ Monitor patients with severe renal impairment (CrCl 10 to 24 mL/min) for signs and symptoms of toxicity. ■ Observe continuously for infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. Antimycotics and/or antivirals may also be indicated. ■ Monitor patients with risk factors for cardiotoxicity. ■ Monitor patients for signs and symptoms of pulmonary toxicity. ■ Use antiemetics for patient comfort. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Effective birth control recommended. Female patients should use highly effective contraception during and for up to 1 year after completion of treatment. Male patients with a female partner who is or may become pregnant should use a condom during and for at least 4 months after treatment. ■ Male and female reproductive function and fertility may be impaired. ■ Interferes with oogenesis and spermatogenesis. May cause sterility in both sexes. ■ Increase fluid intake and void frequently. ■ Promptly report any signs or symptoms of infection, any urinary symptoms, new or worsening shortness of breath, cough, swelling of the ankles/legs, palpitations, weight gain, dizziness, loss of consciousness, or other side effects. ■ See Appendix D, p. 1311.

Maternal/Child:

Category D: may produce fetal harm. ■ Discontinue breast-feeding. ■ Safety profile in pediatric patients similar to that of adults. ■ See Patient Education.

Elderly:

Consider age-related organ impairment. Dose selection should be cautious; see Dose Adjustments. Toxicity may be increased. Monitoring of renal function is suggested.

DRUG/LAB INTERACTIONS

Severe myelosuppression may be expected in patients pretreated with and/or receiving concomitant chemotherapy and/or radiation therapy. ■ Concomitant use of **protease inhibitors** (e.g., atazanavir, indinavir, nelfinavir, ritonavir, saquinavir) may increase the concentration of cytotoxic metabolites. Use of protease inhibitor–based regimens was found to be associated with a higher incidence of infections and neutropenia in patients receiving cyclophosphamide, doxorubicin, and etoposide (CDE) than in patients receiving a nonnucleoside reverse transcriptase inhibitor–based regimen (e.g., delavirdine [Rescriptor], nevirapine [Viramune]). ■ Increased hematotoxicity and/or immunosuppression may result from the combined effect of cyclophosphamide and **ACE inhibitors** (e.g., enalapril, lisinopril), **allopurinol, natalizumab, paclitaxel, thiazide diuretics** (e.g., hydrochlorothiazide), and **zidovudine**. ■ Cardiotoxicity may result from a combined effect of cyclophosphamide and **anthracyclines** (e.g., doxorubicin, liposomal doxorubicin, epirubicin), **cytarabine, pentostatin** (Nipent), **radiation therapy** of the cardiac region, and **trastuzumab**. ■ Increased pulmonary toxicity may result from a combined effect of cyclophosphamide and **amiodarone, filgrastim**, and **sargramostim**. ■ Increased nephrotoxicity may result from the combined effect of cyclophosphamide and **amphotericin B and indomethacin.** ■ Risk of hepatotoxicity is increased when administered with **azathioprine**. ■ Increased incidence of hepatic VOD and mucositis when administered with **busulfan**. ■ Increased incidence of mucositis when administered with **protease inhibitors** (e.g., atazanavir, indinavir, nelfinavir, ritonavir, saquinavir). ■ Increased risk of hemorrhagic cystitis may result from a combined effect of cyclophosphamide and past or concomitant **radiation treatment**. ■ Higher incidence of noncutaneous malignant solid tumors in patients with Wegener's granulomatosis when administered with **etanercept**. ■ Acute encephalopathy has been reported in patients receiving **metronidazole** and cyclophosphamide. ■ Concomitant use with **tamoxifen** may increase the risk of thromboembolic complications. ■ May increase or decrease activity of **anticoagulants** (e.g., warfarin); monitor INR and adjust dose as indicated. ■ May reduce serum **digoxin** and **cyclosporine** levels. ■ May prolong neuromuscular blockade and prolonged respiratory depression caused by **succinylcholine.** These effects are dose dependent and may occur up to several days after cyclophosphamide is discontinued. Alert the anesthesiologist. ■ May decrease effectiveness of oral

quinolone antibiotics (e.g., ciprofloxacin, levofloxacin). ■ Capable of many other interactions.

SIDE EFFECTS

The most commonly reported side effects are alopecia (regrowth may be slightly darker), diarrhea, febrile neutropenia, fever, nausea, neutropenia, and vomiting. Other side effects include abdominal pain, amenorrhea, anorexia, gonadal suppression, impaired wound healing, leukopenia (see Precautions), malaise, mucosal ulcerations, darkening of skin and fingernails, susceptibility to infection, including opportunistic infections.

Major:

Anaphylaxis, bone marrow suppression (anemia, leukopenia, thrombocytopenia) or failure, hemorrhagic cystitis or ureteritis (reversible), infection, pneumonitis, pulmonary fibrosis, rash, renal tubular necrosis (reversible), secondary neoplasia, SIADH, urinary tract and renal toxicity (e.g., bladder fibrosis, hemorrhagic cystitis, ureteritis), veno-occlusive disease.

Post-Marketing:

Numerous side effects have been identified from post-marketing surveillance. These include acute respiratory distress syndrome, arthralgia, ascites, asthenia, bronchospasm, cardiotoxicity (e.g., arrhythmias, cardiac arrest, cardiac failure, cardiogenic shock, cardiomyopathy, myocardial infarction, myocarditis, pericarditis), chest pain, chills, cholestasis, colitis, convulsions, disseminated intravascular coagulation, dizziness, dyspnea, edema, encephalopathy, fatigue, fever, fluid retention, headache, hemolytic-uremic syndrome, hepatic encephalopathy, hepatitis, hepatotoxicity with hepatic failure, hyperglycemia, hypertension, hypoglycemia, hyponatremia, hypotension, increased liver function tests, infusion site reactions, interstitial pneumonitis, malaise, muscle spasms, myalgia, pancreatitis, paresthesia, peripheral neuropathy, pruritus, pulmonary edema, radiation recall dermatitis, reversible posterior leukoencephalopathy syndrome, rhabdomyolysis, Stevens-Johnson syndrome, stomatitis, toxic epidermal necrolysis, visual impairment, and many others.

ANTIDOTE

No specific antidote available. Minor side effects will be treated symptomatically if necessary. Discontinue the drug in cases of severe hemorrhagic cystitis. Urotoxicity may require interruption of treatment or cystectomy. Mesna has been used to decrease the incidence of cystitis. Interrupt therapy, reduce dose, or discontinue in patients who have or who develop potentially serious infections. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Leukocyte and thrombocyte nadirs are usually reached in the first or second week of treatment. Peripheral blood cell counts are expected to normalize after approximately 20 days. Supportive therapy as indicated will help sustain the patient in toxicity. Cyclophosphamide and its metabolites are dialyzable.

CYCLOSPORINE BBW

(sye-kloh-**SPOR**-een)
Sandimmune
Immunosuppressant

USUAL DOSE

Pretreatment:

Baseline studies may be indicated; see Monitor.

Cyclosporine:

5 to 6 mg/kg of body weight as a single dose 4 to 12 hours before transplantation. Repeat once each day until oral dosage form can be tolerated. Individualized adjustment is imperative and may be required on a daily basis. Administered at one-third of the oral dose in patients temporarily unable to take oral cyclosporine. Administered in conjunction with adrenal corticosteroids; different regimens used; see prescribing information.

PEDIATRIC DOSE

Same as adult dose; however, higher doses may be required. See Maternal/Child.

DOSE ADJUSTMENTS

Reduced dose may be required in impaired renal function and in patients with severe hepatic impairment. ■ Higher doses may be required in pediatric patients. ■ Lower-end doses may be indicated in the elderly. Consider impaired organ function and concomitant disease or other drug therapy. ■ Cyclosporine (Sandimmune) is not bioequivalent to Neoral (a brand of cyclosporine oral solution). Conversion from Neoral dosing to Sandimmune may result in lower cyclosporine blood concentrations. Blood concentration monitoring is indicated to avoid potential underdosing. ■ See Monitor and Drug/Lab Interactions.

DILUTION

Each 50 mg should be diluted immediately before use with 20 to 100 mL of NS or D5W and given as an infusion. May leach phthalate from polyvinylchloride containers; use diluents in glass infusion bottles. Dilute immediately before use and discard unused portion.

Filters:

Filtered through a 0.45-micron polypropylene filter during manufacturing. Has a high ethanol content, which the filter must accommodate. A large-bore needle filter may be used when withdrawing cyclosporine from an ampule. Adsorption should be negligible, but if there is concern, draw diluent through the same filter. In-line filtering is acceptable. Manufacturer indicates that cyclosporine molecules are small enough to pass through an in-line filter as small as 0.22 microns. Loss of potency is not expected.

Another source used 0.22- and 0.45-micron filters and indicates an initial loss of potency that recovered to full concentration.

Storage:

Before use, store ampules at CRT. Protect from light. Discard diluted solution after 24 hours.

COMPATIBILITY

Leaches out plasticizers, including DEHP from PVC infusion bags and IV tubing; use of non-PVC containers and IV tubing recommended.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose properly diluted as a slow IV infusion equally distributed over 2 to 6 hours.

ACTIONS

A potent immunosuppressive agent. Interferes with IL-2 production and blocks T-cell proliferative signals during early T-cell activation. Prolongs survival of kidney, liver, and heart allogeneic transplants in the human. Measured by specific or nonspecific assays. Extensively metabolized by the cytochrome P_{450} hepatic enzyme system. Half-life is 19 hours (range 10 to 27 hours). Primarily excreted in bile and to a small extent in urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Prophylaxis of organ rejection in kidney, liver, and heart allogeneic transplants in conjunction with adrenocortical steroids. ■ Treatment of chronic rejection in patients previously treated with other immunosuppressive agents. Reserve parenteral formulation for when oral administration not feasible.

Unlabeled uses:

Decrease frequency of pancreatic or corneal allograft rejection. ■ Prevention of acute graft-versus-host disease. ■ Crohn’s disease.

CONTRAINDICATIONS

Hypersensitivity to cyclosporine or to Cremophor EL (polyoxyethylated castor oil).

PRECAUTIONS

Anaphylactic reactions have been reported with the IV formulation. These reactions may be related to the IV vehicle Cremophor EL; patients who experienced these reactions have subsequently been treated with the oral formulation of cyclosporine without incident. Because of the risk of anaphylaxis, IV cyclosporine should be reserved for patients who are unable to take oral therapy. ■ Usually administered in the hospital by or under the direction of a physician experienced in immunosuppressive therapy and management of organ transplant patients. ■ Adequate laboratory and supportive medical resources must be available. ■ All formulations may be given concomitantly with adrenocortical steroids. Manufacturer has a Black Box Warning. ***Do not administer cyclosporine with any other immunosuppressive agent except adrenocortical steroids.*** ■ Can cause hepatotoxicity and nephrotoxicity; see Monitor. In impaired renal function, if rejection is severe, try other immunosuppressive therapy or allow rejection and removal of the kidney rather than increase dose of cyclosporine. ■ May cause lymphomas and other malignancies, particularly those of the skin. Increased risk of developing a malignancy appears to be related to the intensity and duration of immunosuppression. Some malignancies may be fatal. ■ Patients receiving immunosuppressive therapies, including cyclosporine and cyclosporine-containing regimens, are at increased risk for infections (viral, bacterial, fungal, protozoal). Both generalized and localized infections can occur. Opportunistic infections include polyomavirus infections (e.g., JC virus–associated progressive multifocal leukoencephalopathy [PML]; polyoma virus–associated nephropathy [PVAN], especially due to BK virus infection). Pre-existing infections may be aggravated. Latent infections may be reactivated. Fatal outcomes have been reported. ■ Encephalopathy has been reported, including posterior reversible encephalopathy syndrome (PRES). May be manifest as impaired consciousness, convulsions, visual disturbances (including blindness), loss of motor function, movement disorders, and psychiatric disturbances. Predisposing factors may include hypertension, hypomagnesemia, hypocholesterolemia, high-dose corticosteroids, high cyclosporine blood levels, and graft-versus-host disease. Patients receiving liver transplants may be more susceptible to encephalopathy than patients receiving kidney transplants. Reversal of encephalopathy has occurred after discontinuation or dose reduction of cyclosporine. ■ Convulsions have been reported, particularly in patients receiving concomitant therapy with high-dose methylprednisolone. ■ Significant hyperkalemia (sometimes associated with hyperchloremic acidosis) and hyperuricemia have been reported. ■ A syndrome of thrombocytopenia and microangiopathic hemolytic anemia that may result in graft failure has been reported. ■ Optic disc edema, including papilledema, with possible visual impairment secondary to benign intracranial hypertension has been reported. ■ See Drug/Lab Interactions.

Monitor:

Observe for S/S of an anaphylactic reaction (e.g., blood pressure changes; bronchospasm; dyspnea; edema of face, tongue, or throat; itching; rash; tachycardia; wheezing). Monitor continuously for the first 30 minutes of the infusion and frequently thereafter. ■ Can cause hepatotoxicity and nephrotoxicity. Monitor BUN, SCr, serum bilirubin, and liver enzymes frequently. Timing and amount of rise in BUN and creatinine and degree of nephrotoxicity or hepatotoxicity distinguish between need for dose reduction or symptoms of organ rejection. ■ May be difficult to distinguish between nephrotoxicity and rejection. Up to 20% of patients may have simultaneous nephrotoxicity and rejection. See package insert for a chart discussing differential diagnoses for each. ■ Monitor cyclosporine blood levels. Measured by specific or nonspecific assay. 24-hour specific trough values of 100 to 200 ng/mL of whole blood or 24-hour nonspecific trough values of 250 to 800 ng/mL of whole blood minimize side effects and rejection events. Nonspecific assays trough values are higher because they include metabolites. Plasma levels may range from ½ to $_{1}/^{5}$ of whole blood levels. Consistent use of one assay is recommended. Confirm assay method to evaluate appropriately. ■ Observe constantly for signs of infection (fever, sore throat, tiredness) or unusual bleeding or bruising. ■ Prophylactic antibiotics may be indicated pending results of C/S. ■ Monitor for development of PVAN and BK virus–associated nephropathy (e.g., deteriorating renal function and renal graft loss). Dose reduction may be indicated. ■ Monitor for development of PML (e.g., apathy, ataxia, cognitive deficiencies, confusion, hemiparesis). If symptoms appear, consultation with a neurologist may be indicated. ■ Monitor BP. Hypertension is a common side effect. Initiation or modification of antihypertensive therapy may be indicated; do not use potassium-sparing diuretics (e.g., spironolactone [Aldactone]); may increase risk of hyperkalemia. ■ Monitor for S/S of encephalopathy and/or PRES. ■ See Precautions and Drug/Lab Interactions.

Patient Education:

Use effective birth control. Do not use oral contraceptives. See Appendix D, p. 1311. ■ Do not make any changes in formulation (e.g., IV, capsules, oral solution) without physician direction; products are not equivalent. May require dose adjustment. ■ Review side effects with a health care professional and report all side effects promptly. ■ Capable of multiple drug-drug interactions; obtain physician approval before adding or stopping medications. ■ Compliance with frequent laboratory tests is imperative.

Maternal/Child:

Category C: safety for use in pregnancy not established. Should not be used unless benefit to the mother justifies potential risk to the fetus. Use in men and women capable of conception not established. Reported outcomes of pregnancies in women who received cyclosporine are difficult to evaluate. It is not possible to separate the effects of cyclosporine from the effects of other medications, underlying maternal disorders, or other aspects of the transplantation process. Negative outcomes included prematurity, low birth weight, fetal loss, and various malformations. ■ Discontinue breast-feeding. ■ Safety for use in pediatric patients not established but has been used in patients as young as 6 months. Accidental parenteral overdose in premature neonates has caused serious symptoms of intoxication.

Elderly:

Dose selection should be cautious; see Dose Adjustments. ■ Differences in response compared to younger adults not identified.

DRUG/LAB INTERACTIONS

Interactions are numerous and potentially life threatening. Review of drug profile by pharmacist imperative. ■ Risk of nephrotoxicity increased when given with other drugs that may potentiate renal dysfunction. Use extreme caution and monitor renal function closely. If impairment of renal function is significant, either reduce the dose of cyclosporine and/or the coadministered drug, or consider an alternative treatment. Manufacturer lists **antibiotics** (e.g., ciprofloxacin, gentamicin, tobramycin, sulfamethoxazole/trimethoprim, vancomycin), **antifungals** (e.g., amphotericin B, ketoconazole), **anti-inflammatory drugs** (e.g., azapropazone, colchicine, diclofenac, naproxen, sulindac), **H_2 antagonists** (e.g., cimetidine, famotidine), **immunosuppressives** (e.g., tacrolimus), **antineoplastics, and fibric acid derivatives** (e.g., fenofibrate). Other sources list **acyclovir, foscarnet** (Foscavir), **selected quinolones, and numerous other nephrotoxic drugs**. ■ Concurrent administration with **colchicine** may cause cyclosporine toxicity (e.g., GI, hepatic, renal, and neuromuscular toxicity). Cyclosporine may decrease the clearance and increase the toxic effects of colchicine (e.g., myopathy, neuropathy), especially in patients with renal impairment. With concurrent use, close clinical observation is required. Reduce colchicine dose or discontinue as indicated. ■ May increase **diclofenac** (Voltaren) serum levels with concomitant administration; initiate diclofenac dose at the lower end of the therapeutic range. ■ Cyclosporine is extensively metabolized by CYP3A4 and is a substrate of the multidrug efflux transporter P-glycoprotein. **Drugs that inhibit or induce CYP3A4, P-glycoprotein transporter, or organic anion transporter proteins** will result in an alteration of cyclosporine concentrations. Toxicity or allograft rejection may occur. Compounds that decrease cyclosporine absorption, such as **orlistat**, should be avoided. ■ Cyclosporine plasma levels may be increased with concurrent use of **protease inhibitors** (e.g., boceprevir, indinavir, nelfinavir, ritonavir, saquinavir, telaprevir), which are metabolized by cytochrome P_{450} 3A; use caution. ■ Drugs that inhibit the cytochrome P_{450} system may decrease the metabolism of cyclosporine and increase its serum concentrations. Manufacturer lists **allopurinol, amiodarone, antibiotics** (e.g., azithromycin, clarithromycin, erythromycin, quinupristin/dalfopristin), **antifungals** (e.g., fluconazole, voriconazole), **bromocriptine, calcium channel blockers, danazol, glucocorticoids, imatinib, metoclopramide, nefazodone, and oral contraceptives.** Monitor blood levels with concurrent use to avoid cyclosporine toxicity. ■ Drugs that decrease cyclosporine concentrations should be avoided. Manufacturer lists **antibiotics, anticonvulsants, bosentan, octreotide, orlistat, terbinafine, St. John's wort, and sulfinpyrazone**. Other sources list **sulfamethoxazole/trimethoprim;** monitor levels and adjust cyclosporine dose as indicated to avoid transplant rejection. ■ **Rifabutin** (Mycobutin) may increase metabolism of cyclosporine; use care with concomitant use. ■ Cyclosporine inhibits CYP3A4 and the multidrug efflux transporter P-glycoprotein and may increase plasma concentrations of co-medications that are substrates of CYP3A4, P-glycoprotein, or organic anion transporter proteins. Cyclosporine reduces clearance and may increase blood levels of **ambrisentan, bosentan, dabigatran, digoxin, etoposide, methotrexate, NSAIDs, prednisolone, repaglinide, sirolimus, and other drugs**. May decrease the volume distribution of **digoxin** and cause toxicity rather quickly. With concurrent use, monitor digoxin levels, reduce digoxin dose, or discontinue as indicated. ■ Concomitant use with **NSAIDs,** particularly in dehydrated patients, may potentiate renal dysfunction. ■ Avoid concurrent use with **bosentan.** ■ When coadministering **ambrisentan** with cyclosporine, the ambrisentan dose should ***not*** be titrated to the recommended maximum daily dose. ■ Cyclosporine may decrease the clearance of **HMG-CoA reductase inhibitors (statins)**. Cases of myotoxicity (including muscle pain and weakness, myositis, and rhabdomyolysis) have been reported with concomitant use. Dose reduction of statins is indicated. Statins may be temporarily withheld or discontinued in patients with S/S of myopathy or potential for renal injury, including renal failure, secondary to rhabdomyolysis. ■ Coadministration with **aliskiren** (Tekturna) is not recommended. ■ May decrease **mycophenolate** levels. Monitor levels closely when cyclosporine is added or removed from a drug regimen containing mycophenolate. ■ Concurrent use of cyclosporine with **imipenem-cilastatin** may increase CNS toxicity of both agents. ■ Potentiates **nondepolarizing muscle relaxants**; will prolong neuromuscular blockade. ■ Do not use **potassium-sparing diuretics**; may increase risk of hyperkalemia. Use caution when coadministered with **other potassium-sparing drugs**, **potassium-containing drugs,** and/or in patients on a **potassium-rich diet.** Hyperkalemia can occur. ■ May cause convulsions with high doses of **methylprednisolone.** ■ May be given in combination with **steroids** but has additive effects with other **immunosuppressive agents;** may increase risk of lymphoma. ■ Concurrent administration with **sirolimus** increases blood levels of sirolimus. To minimize the effect on blood levels, administer sirolimus 4 hours after cyclosporine dose. ■ Elevations in SCr have been reported with coadministration of **sirolimus** and cyclosporine. Effect is usually reversible with cyclosporine dose reduction. ■ Serum levels may increase with **chloroquine** (Aralen). ■ Avoid use in psoriasis patients receiving **other immunosuppressive agents or radiation therapy, including PUVA and UVB.** Immunosuppression may be excessive. ■ May increase the plasma concentrations of **repaglinide**, which increases the risk for hypoglycemia. Monitor blood glucose levels closely. ■ Concurrent use with **nifedipine** has caused gingival hyperplasia; avoid use in patients who develop gingival hyperplasia. ■ High doses of cyclosporine (e.g., IV doses of 16 mg/kg/day) may increase the exposure to **anthracycline antibiotics** in cancer patients. ■ Monitor serum creatinine when used with **NSAIDs** in rheumatoid arthritis patients. ■ Vaccinations may be less effective. Avoid use of **live virus vaccines** in patients receiving cyclosporine. ■ **Grapefruit juice** may affect certain enzymes of the P_{450} enzyme system and should be avoided.

SIDE EFFECTS

The most common side effects include gum hyperplasia, hirsutism, hypertension, renal dysfunction, and tremor. Other side effects include acne, convulsions, cramps, diarrhea, encephalopathy, glomerular capillary thrombosis, headache, hepatotoxicity, hyperkalemia, hyperuricemia, hypomagnesemia, infection, leukopenia, lymphoma, microangiopathic hemolytic anemia, nausea and vomiting, paresthesia, skin rash, and thrombocytopenia. Hypersensitivity reactions including anaphylaxis have occurred. Stevens-Johnson syndrome and toxic epidermal necrolysis have occurred rarely.

Post-Marketing:

Headache, including migraine; hepatotoxicity and liver injury, including cholestasis, hepatitis, jaundice, and liver failure with serious and/or fatal outcomes; isolated cases of pain in the lower extremities; JC virus–associated PML, sometimes fatal; and PVAN, especially due to BK virus infection, resulting in graft loss.

ANTIDOTE

Notify physician of all side effects. Most can be treated symptomatically. Drug may be decreased or discontinued or other immunosuppressive agents utilized. Consider reducing total immunosuppression in transplant patients who develop PML or PVAN; may place graft at risk. Discontinue infusion at the first sign of a severe hypersensitivity reaction. Treat hypersensitivity as indicated; may require oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors, corticosteroids, albuterol, IV fluids, and/or ventilation equipment. Nephrotoxicity, hepatotoxicity, encephalopathy (including PRES), or hematopoietic depression may require temporary reduction of dosage or permanent withholding of treatment. Dialysis is not effective in overdose.

CYSTEINE HYDROCHLORIDE

(**SIS**-te-een)
Elcys, Nouress
Amino acid
pH 1 to 2.5

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Cysteine:

Dose should be individualized based on the patient's clinical condition (ability to adequately metabolize amino acids), body weight, and nutritional/fluid requirements, as well as additional energy given orally/enterally to the patient. Before initiating parenteral nutrition, review all medications, gastrointestinal function, and laboratory data (e.g., electrolytes [including magnesium, calcium, and phosphorus], glucose, urea/creatinine, liver panel, complete blood count, and triglyceride level [if adding lipid emulsion]).

Recommended daily doses for Elcys and Nouress are based on recommended daily protein (amino acid) requirement and are included in the following charts.

Recommended Daily Dose of Elcys in Pediatric Patients and Adults

Age	Recommended Protein[a] Requirement (Gm AA/kg/day)[b]	Recommended Dosage (mg Elcys/Gm AA)	Recommended Volume (mL Elcys/Gm AA)
Preterm and term infants under 1 month of age	3 to 4 Gm/kg/day	22 mg	0.44 mL
Pediatric patients 1 month to under 1 year of age	2 to 3 Gm/kg/day	22 mg	0.44 mL
Pediatric patients 1 to 11 years of age	1 to 2 Gm/kg/day	22 mg	0.44 mL
Pediatric patients 12 to 17 years of age	0.8 to 1.5 Gm/kg/day	7 mg	0.14 mL
Adults: Stable patients	0.8 to 1 Gm/kg/day	7 mg	0.14 mL
Adults: Critically ill patients[b]	1.5 to 2 Gm/kg/day	7 mg	0.14 mL

[a] Protein is provided as amino acids (AA).

[b] Includes patients requiring more that 2 to 3 days in the ICU with organ failure, sepsis, or postoperative major surgery. Do not use in patients with conditions that are contraindicated.

AA, Amino acid.

Recommended Daily Dose of Nouress in Neonates (Preterm and Term Infants Under 1 Month of Age)

Dosage	Protein[a] Requirement (Gm AA/kg/day)	Dosage (mg Nouress/Gm AA)	Volume (mL Nouress/Gm AA
Neonates	3 to 4 Gm/kg/day	22 mg	0.44 mL

[a] Protein is provided as amino acids (AA).

DILUTION

Available as a clear, colorless solution in 10-mL single-dose vials containing 500 mg/10 mL (50 mg/mL). **Must be diluted and used as an admixture in the parenteral nutrition (PN) solution.** Strict aseptic techniques must be used throughout the mixing process. Review manufacturer's specific instructions in prescribing information. Initially transfer the desired amount of cysteine into the amino acid solution (this will be used later in the mixing process). Amino acid solution containing cysteine may be mixed with dextrose injection. A specific mixing sequence must be followed to minimize pH-related problems.

- ***First,*** transfer dextrose injection into the parental nutrition pooling container;
- ***Second,*** transfer phosphate salt;

- ***Third,*** transfer the cysteine-containing amino acid solution;
- ***Fourth,*** transfer electrolytes; and
- ***Fifth,*** transfer trace elements into the pooling container. Use gentle agitation during admixing to minimize localized concentration effects; shake containers gently after each addition. Evaluate all additions for compatibility and stability; consult a pharmacist. If an automated compounder is to be used, refer to its instructions for use. Inspect the final PN solution to ensure that precipitates have not formed. Discard if any precipitates are observed.

Filters:

Elcys: Use a 0.22-micron in-line filter for administration without lipid emulsion.

Nouress:

Use a 0.22-micron in-line filter for administration.

Storage:

Both formulations:

Store unopened vials at CRT. Avoid excessive heat. Protect from freezing. If accidentally frozen, discard the vial. Promptly use mixed solutions. Any storage of the admixture should be under refrigeration at 2° to 8° C (36° to 46° F) and limited to no longer than 24 hours. After removal from the refrigerator, inspect for precipitates, use promptly, and complete the infusion within 24 hours. Discard if precipitates are observed. Discard any remaining admixture. ***Nouress***: Protect from light. Vial stoppers are not made with natural rubber latex.

COMPATIBILITY

Calcium and phosphate ratios must be considered. Excess addition of calcium and phosphate, especially in the form of mineral salts, may result in the formation of calcium phosphate precipitates. ***Elcys:*** If infused with lipid emulsion, do not use administration sets and lines that contain di-2-ethylhexyl phthalate (DEHP). Administration sets that contain polyvinyl chloride (PVC) components have DEHP as a plasticizer.

RATE OF ADMINISTRATION

Use a dedicated line for PN solutions. Infuse into a central or peripheral line. Choice of venous route depends on osmolarity of the final infusate. Solutions with osmolarity of 900 mOsm/L or greater must be infused through a central catheter. Use a nonvented infusion set to prevent air embolism. Infuse at the prescribed rate. IV lipid emulsions can be infused concurrently into the same vein as the prepared PN solution by a Y-connector located near the infusion site. Flow rates of each solution should be controlled by separate infusion pumps.

ACTIONS

Endogenous cysteine is synthesized from methionine by the enzyme cystathionase via the trans-sulfuration pathway and serves as a precursor substrate for both glutathione and taurine. Provides cysteine to the systemic circulation of patients who require PN and cannot synthesize adequate quantities of cysteine due to insufficient or deficient cystathionase activity

INDICATIONS AND USES

Eycls:

Indicated for use as an additive to amino acid solutions to meet the nutritional requirements of newborn infants requiring total parenteral nutrition (TPN) and of adult and pediatric patients with severe liver disease who may have impaired enzymatic processes and require TPN. It can also be added to amino acid solutions to provide a more complete profile of amino acids for protein synthesis.

Nouress:

Indicated for use as an additive to amino acids solutions to meet nutritional requirements of neonates (preterm and term infants under 1 month of age) requiring TPN.

CONTRAINDICATIONS

Known hypersensitivity to one or more amino acids. ■ Patients with inborn errors of amino acid metabolism due to risk of severe metabolic or neurologic complications. ■ Patients with pulmonary edema or acidosis due to low cardiac output.

PRECAUTIONS

Must be diluted and used as an admixture in PN solutions; ***NOT for direct IV infusion***. ■ Before administration of PN solutions, correct severe fluid, electrolyte, and acid-base disorders. ■ Pulmonary vascular precipitates causing pulmonary vascular emboli and pulmonary distress have been reported in patients receiving PN. In some fatal cases, pulmonary embolism occurred as a result of calcium phosphate precipitates. Precipitation following passage through an in-line filter and suspected in vivo precipitate formation have also been reported. ■ The infusion of hypertonic nutrient injections into a peripheral vein may result in vein irritation, vein damage, and/or thrombosis. Cysteine must be diluted, and solutions with an osmolarity of 900 mOsm/L or greater must be infused through a central catheter. ■ IV infusion of amino acids may induce a rise in blood urea nitrogen (BUN), especially in patients with impaired hepatic or renal function. ■ Administration may result in metabolic acidosis in preterm infants, and serum amino acid imbalances, metabolic alkalosis, prerenal azotemia, hyperammonemia, stupor, and coma in patients with hepatic impairment. ■ Hepatobiliary disorders are known to develop in some patients without pre-existing liver disease who receive PN, including cholecystitis, cholelithiasis, cholestasis, hepatic steatosis, fibrosis, and cirrhosis, possibly leading to hepatic failure. ■ Contains aluminum that may be toxic. Aluminum may reach toxic levels with prolonged parenteral administration in patients with renal impairment. Preterm infants are particularly at risk for aluminum toxicity because their kidneys are immature and because they require large amounts of calcium and phosphate solutions, which also contain aluminum. Amounts greater than 4 to 5 mcg/kg/day of parenteral aluminum can accumulate aluminum to levels associated with CNS and bone toxicity. These toxicities may occur at lower rates of administration.

Monitor:

Obtain baseline CBC, electrolytes (including calcium, magnesium, and phosphorus), glucose, liver panel, urea/creatinine, and triglyceride level (if adding lipid emulsion). ■ Monitor fluid and electrolyte status, serum osmolarity, blood glucose, liver and kidney function, blood count, and coagulation parameters throughout treatment. ■ Monitor patients with hepatic or renal impairment frequently to assess function and fluid balance. ■ Monitor acid-base balance. Significant deviations from normal concentrations may require the use of additional electrolyte supplements. ■ Monitor for S/S of pulmonary distress. ■ Monitor the infusion site and catheter periodically for precipitates and signs of vein irritation. Venous thrombophlebitis is the primary complication of peripheral access. Remove catheter as soon as possible if thrombophlebitis develops. ■ Monitor for hepatobiliary disorders (acid-base balance, liver function parameters, and ammonia levels). A clinician knowledgeable in liver disease should assess patients developing signs of hepatobiliary disorders early to identify possible causative and contributory factors and possible therapeutic and prophylactic interventions. ■ Hyperammonemia in infants can result in neurocognitive delays. Monitor blood ammonia levels frequently in infants. ■ Monitor for aluminum toxicity. Elcys aluminum exposure is not more than 0.21 mcg/kg/day at recommended doses. Nouress exposure is not more than 0.25 mcg/kg/day at recommended doses.

Patient Education:

Frequent laboratory monitoring required. ■ Promptly report any irritation at the infusion site, shortness of breath, or other unexpected side effects.

Maternal/Child:

Neither formulation is expected to cause major birth defects, miscarriage, or adverse maternal or fetal outcomes. Nouress is not approved for use in adults. ■ Data available on the effects of cysteine on infants, either directly or through breast milk, do not suggest a significant risk of adverse reactions from exposure. ■ Safety and efficacy established for use in pediatric patients; see Indications. ■ Hyperammonemia in infants can result in neurocognitive delays. Monitor blood ammonia levels frequently in infants.

Elderly:

Clinical studies with Elcys have not been performed to determine whether patients 65 years of age and over respond differently from younger patients.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Most common adverse reactions are fever, generalized flushing, local reactions (erythema, phlebitis, thrombosis at the infusion site, and warm sensation), and nausea. ***Nouress*** adds metabolic acidosis. Serious adverse reactions include acid-base imbalance, aluminum toxicity, hepatobiliary disorders, hyperammonemia, increased BUN, pulmonary embolism due to pulmonary vascular precipitates, and vein damage and thrombosis.

Overdose:

Overhydration or solute overload may occur.

ANTIDOTE

Notify the physician of all side effects. Adverse reactions related to PN may respond to an adjustment in amino acids, dextrose, or other additives and/or an adjustment in rate. Treat symptomatically and resuscitate as necessary. Stop infusion immediately for any signs of pulmonary distress, and initiate a medical evaluation. In the event of overhydration or solute overload from overdosage, re-evaluate the patient and institute appropriate corrective measures.

CYTARABINE BBW

(sye-**TAIR**-ah-bean)
ARA-C, Cytosar 🍁 , Cytosar-U 🍁
Antineoplastic (antimetabolite)
pH 7.4 to 7.7

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Dose is variable depending on specific regimen or protocol. Consult guidelines for current treatment regimens.

Acute nonlymphocytic leukemia in adult and pediatric patients:

Combination chemotherapy:

Manufacturer lists a dose of 100 mg/M^2/24 hr as a continuous infusion or 100 mg/M^2 as an IV injection every 12 hours. Repeat daily on Days 1 through 7.

Acute myelocytic leukemia or erythroleukemia in adult and pediatric patients:

Manufacturer lists a dose of 100 mg/M^2/24 hr as a continuous infusion or 200 mg/M^2/day continuous infusion (as 100 mg/M^2 over 12 hours every 12 hours) for 7 days.

DOSE ADJUSTMENTS

Dose reduction may be indicated in impaired hepatic or renal function. ■ See Precautions/Monitor. ■ Usually used with other antineoplastic drugs in specific doses to achieve tumor remission. ■ Withhold or modify dose based on degree of bone marrow suppression; see Monitor.

DILUTION

Specific techniques required; see Precautions.

Available in multiple concentrations. Read label carefully. May be given by IV injection as is or further diluted in NS or D5W and given as an infusion. Use only clear solutions.

Storage:

Store unused vials at CRT in carton to protect from light. When infusion solutions are prepared in D5W or NS, 94% to 96% of cytarabine remains present after 8 days. Immediate use preferred.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

Each 100 mg or fraction thereof over 15 to 30 minutes. When large IV doses are given too quickly, patients are frequently nauseated and may vomit for several hours postinjection. This problem tends to be less severe when the drug is infused.

IV infusion:

Single daily dose properly diluted over 30 minutes to 24 hours, depending on amount of infusion solution and dosage regimen.

ACTIONS

An antimetabolite that inhibits synthesis of DNA. Cell-cycle specific for S phase. It is a pyrimidine analog that is incorporated into DNA. It inhibits DNA polymerase, resulting in decreased DNA synthesis and repair. Through various chemical processes this deprivation acts more quickly on rapidly growing cells and causes their death. A potent bone marrow suppressant. Crosses the blood-brain barrier. Serum half-life averages 1 to 3 hours. Metabolized in the liver and excreted in the urine.

INDICATIONS AND USES

Used in combination with other approved anticancer drugs for remission induction in acute nonlymphocytic leukemia in adults and pediatric patients. Also used for treatment of acute lymphocytic leukemia (ALL), the blast phase of chronic myelocytic leukemia, and acute myelocytic leukemia (AML). ■ Is used intrathecally in the treatment of meningeal leukemia. A liposomal formulation (DepoCyt) is available for intrathecal use only; lipofoam molecules contained in this product are much too large for IV use.

CONTRAINDICATIONS

Hypersensitivity to cytarabine, pre-existing drug-induced bone marrow suppression.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. Must be able to monitor drug tolerance and protect and maintain a patient compromised by drug toxicity. The main toxic effect of cytarabine is bone marrow suppression with leukopenia, thrombocytopenia, and anemia. Complications of bone marrow suppression include infection resulting from granulocytopenia and hemorrhage secondary to thrombocytopenia. Use with caution in patients with pre-existing drug-induced bone marrow suppression. Less serious toxicity includes nausea, vomiting, diarrhea and abdominal pain, oral ulceration, and hepatic dysfunction. Weigh benefit versus risk of known toxic effects before initiating therapy. ■ Remissions induced by cytarabine are brief unless followed by maintenance therapy. ■ Severe, and sometimes fatal, GI, pulmonary, cardiac, or CNS toxicity has occurred with experimental cytarabine regimens. Toxicities are different (e.g., reversible corneal toxicity, hemorrhagic conjunctivitis, cerebral and cerebellar dysfunction, severe GI ulceration) from those seen with conventional therapy. Deaths have been reported. ■ Cases of cardiomyopathy and a syndrome of sudden respiratory distress rapidly progressing to pulmonary edema and radiographically pronounced cardiomegaly have been reported following experimental high-dose therapy. ■ Do not use product containing benzyl alcohol if experimental high-dose therapy is administered. ■ Use with caution and possibly at reduced doses in patients with renal or hepatic impairment. ■ May induce hyperuricemia (tumor lysis syndrome) secondary to rapid lysis of neoplastic cells. ■ Acute pancreatitis has been reported in patients receiving cytarabine by continuous infusion and in patients being treated with cytarabine who have had prior treatment with L-asparaginase.

Monitor:

Leukocyte and platelet counts should be monitored daily. ■ During induction therapy, WBC depression is biphasic with the first nadir occurring at Days 7 to 9 and a deeper fall at Days 15 to 24. Platelet depression begins around Day 5 and reaches a nadir at Days 12 to 15. ■ Hold or modify therapy for platelet count less than 50,000 or polymorphonuclear granulocytes less than 1,000 cells/mm^3. Counts may continue to fall after the drug is stopped and may reach lowest values after drug-free intervals of 12 to 14 days. Restart therapy when bone marrow recovery is confirmed. Patients whose drug is withheld until “normal” peripheral blood values are attained may escape from control. ■ Monitor hepatic and renal function at regular intervals during therapy. ■ Perform bone marrow examinations frequently after blasts have disappeared from the peripheral blood. ■ Higher total doses tolerated by IV injection compared with IV infusion, but the incidence and intensity of nausea and vomiting are increased. ■ Prophylactic administration of antiemetics recommended. ■ Be alert for signs of bone marrow suppression, bleeding, infection, or neurotoxicity. These side effects are dose- and schedule-dependent. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor uric acid levels and maintain hydration; allopurinol may be indicated. ■ Monitor for S/S of pancreatitis (e.g., elevated amylase, nausea, vomiting, upper abdominal pain).

Patient Education:

Effective birth control recommended. ■ See Appendix D, p. 1311. ■ Promptly report early signs of neurotoxicity (e.g., ataxia, confusion, lethargy) or bone marrow suppression (e.g., infection, bleeding).

Maternal/Child:

Avoid pregnancy. Can cause fetal harm when administered to a pregnant woman, especially during the first trimester. ■ Discontinue breast-feeding. ■ Benzyl alcohol may cause a fatal “gasping syndrome” in premature infants. ■ See Drug/Lab Interactions.

Elderly:

Consider age-related organ impairment; toxicity may be increased.

DRUG/LAB INTERACTIONS

May inhibit **digoxin** absorption. ■ Do not administer any **live virus vaccines** to patients receiving antineoplastic drugs. ■ May cause acute pancreatitis in patients who previously received **L-asparaginase.** ■ May antagonize action of **gentamicin** against *Klebsiella*. ■ May antagonize antifungal actions of **flucytosine**.

SIDE EFFECTS

Abdominal pain, anorexia, bleeding, bone marrow suppression (e.g., anemia, leukopenia, thrombocytopenia), bone pain, cardiomyopathy, chest pain, conjunctivitis, diarrhea, esophagitis, fever, hepatic dysfunction, hypersensitivity reactions, hyperuricemia, malaise, megaloblastosis, mucosal bleeding, myalgia, nausea, oral and anal ulceration, pancreatitis, peripheral motor and sensory neuropathies, rash, stomatitis, thrombophlebitis, vomiting. Higher than usual dose regimens may cause severe coma, GI ulcerations and peritonitis, personality changes, pulmonary toxicity, somnolence, or death.

ANTIDOTE

Notify the physician of all side effects. Most will be treated symptomatically. Some toxicity is necessary to produce remission. Discontinue or withhold the drug for serious bone marrow suppression. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. Drug must be restarted as soon as signs of bone marrow recovery occur, or its effectiveness will be lost. Use corticosteroids for cytarabine syndrome (fever, myalgia, bone pain, occasional chest pain, maculopapular rash, conjunctivitis, malaise). Usually occurs in 6 to 12 hours after administration. Continue cytarabine if patient responds to corticosteroids. There is no specific antidote; supportive therapy as indicated will help to sustain the patient in toxicity.

CYTOMEGALOVIRUS IMMUNE GLOBULIN INTRAVENOUS (HUMAN) BBW *

(**sigh**-toh-**meg**-ah-lo-**VIGH**-rus ih-**MUNE** GLAW-byoo-lin)
CMV-IGIV, CytoGam
Passive immunizing agent
Antibacterial
Antiviral

USUAL DOSE

150 mg/kg is the maximum recommended dose per infusion.

Kidney transplant:

150 mg/kg of body weight as an IV infusion. This initial dose must be given within 72 hours of transplant. Additional infusions of 100 mg/kg are given at 2, 4, 6, and 8 weeks posttransplant, then reduced to 50 mg/kg at 12 and 16 weeks posttransplant.

Heart, liver, lung, and pancreas transplants:

150 mg/kg of body weight as an IV infusion. This initial dose must be given within 72 hours of transplant. Consider use in combination with ganciclovir (Cytovene) 10 mg/kg/day for 14 days. Additional infusions of cytomegalovirus IGIV containing 150 mg/kg are given at 2, 4, 6, and 8 weeks posttransplant, then reduced to 100 mg/kg at 12 and 16 weeks posttransplant.

DILUTION

Absolute sterile technique required; contains no preservatives. Available in 20- and 50-mL vials (50 mg/mL); multiple vials may be required. Use only if clear and colorless. Enter vial only once and initiate infusion within 6 hours. Must be completely infused within 12 hours of dilution. See Rate of Administration.

Filters:

Use of an in-line filter (pore size 15 microns [0.2 microns acceptable]) is required; see Rate of Administration.

Storage:

Store dry powder in refrigerator between 2° and 8° C (35° to 46° F).

COMPATIBILITY

Administration through a separate infusion line recommended. If absolutely necessary, may be piggybacked in a pre-existing line containing NS, ½NS, dextrose 2.5%, 5%, 10%, or 20% in water or saline. Do not dilute CMV-IGIV more than one part to two parts of any of these solutions.

RATE OF ADMINISTRATION

Use of an in-line filter (pore size 15 microns [0.2 microns acceptable]) and a constant infusion pump (e.g., IVAC) is required. Begin with a rate of 15 mg/kg/hr. May be increased to 30 mg/kg/hr in 30 minutes if no discomfort or adverse effects. May be increased in another 30 minutes to 60 mg/kg/hr if no discomfort or adverse effects. Do not exceed the 60 mg/kg/hr rate or allow the volume infused to exceed 75 mL/hr regardless of mg/kg/hr dose. Slow rate of infusion at onset of patient discomfort or any adverse reactions. Infusion must be complete within 12 hours of dilution. Subsequent doses may be increased at 15-minute intervals using the same mg/kg/hr rates and adhering to the volume maximum of 75 mL/hr.

ACTIONS

A sterile solution of immunoglobulin G (IgG). Derived from pooled adult human plasma selected for high titers of antibody for cytomegalovirus (CMV). Purified by a specific process. Can raise the relevant antibody levels sufficiently to attenuate or reduce the incidence of serious CMV disease. Antibody levels will last 2 to 3 weeks. Recent studies of combined prophylaxis with CMV-IGIV and ganciclovir have shown reductions in the incidence of serious CMV-associated disease in CMV-seronegative recipients of CMV-seropositive organs below that expected from one drug alone.

INDICATIONS AND USES

Prophylaxis of CMV disease associated with transplantation of kidney, heart, liver, lung, and pancreas. In transplants of these organs other than kidney from CMV-seropositive donors to seronegative recipients, prophylactic CMV-IGIV should be considered in combination with ganciclovir.

CONTRAINDICATIONS

History of a prior severe reaction associated with any human immunoglobulin preparations. Individuals with selective immunoglobulin A deficiency may develop antibodies to IgA and are at risk for anaphylaxis.

PRECAUTIONS

75% of untreated recipients would be expected to develop CMV disease. Use of CMV-IGIV has effected a 50% reduction in this disease rate. Effective results have been obtained with a variety of immunosuppressive regimens (e.g., combinations of azathioprine, cyclosporine, prednisone). ■ A fatal CMV infection occurred even with ganciclovir treatment in one patient, who inadvertently missed a single injection.

Monitor:

Continuous monitoring of vital signs is preferred. Must be monitored before infusion, at every rate change, at the midpoint, at the conclusion, and several times after completion. ■ All supplies for emergency treatment of acute anaphylactic reaction must be available; see Antidote.

Patient Education:

Adherence to the prescribed regimen is imperative.

Maternal/Child:

Category C: safety for use during pregnancy or breast-feeding not established. Use only if clearly needed.

DRUG/LAB INTERACTIONS

Defer vaccination with any **live virus vaccine** (e.g., measles, mumps, rubella) until 3 months after CMV-IGIV administration.

SIDE EFFECTS

Incidence related to rate of administration; back pain, chills, fever, flushing, hypotension, muscle cramps, nausea, vomiting, wheezing. Hypersensitivity reactions, including anaphylaxis, are possible.

ANTIDOTE

With onset of any minor side effect, reduce rate of infusion immediately or discontinue temporarily. Discontinue CMV-IGIV if symptoms persist, and notify the physician. May be treated symptomatically and infusion resumed at a slower rate if symptos subside. Discontinue CMV-IGIV if hypotension or anaphylaxis occur and treat immediately. Epinephrine, diphenhydramine, oxygen, vasopressors, corticosteroids, and ventilation equipment must always be available. Resuscitate as necessary.

---

*This drug is on the Black Box Warning list; however, a BBW is not provided in the parenteral prescribing information.

(dah-**KAR**-bah-zeen)
DTIC, DTIC-Dome
Antineoplastic (alkylating agent)
pH 3 to 4

USUAL DOSE

Pretreatment:

See Maternal/Child.

Malignant melanoma:

2 to 4.5 mg/kg of body weight/24 hr for 10 days. May be repeated at 4-week intervals. May administer 250 mg/M^2 daily for 5 days. Repeat in 3 weeks. Has proved as effective in lesser doses as in larger doses. Individualized response determines dosage of subsequent treatments.

Hodgkin disease:

150 mg/M^2/24 hr for 5 days. Repeat every 4 weeks. Used in combination with other drugs in a specific regimen. An alternate regimen is 375 mg/M^2 on Days 1 and 15 every 4 weeks or 100 mg/M^2/day for 5 days. Given as part of a specific protocol.

DOSE ADJUSTMENTS

Dose (mg/kg) based on average weight in presence of edema or ascites. ■ Used with other antineoplastic drugs and radiation therapy in reduced doses to achieve tumor remission. ■ Dose reduction may be required in impaired liver and renal function.

DILUTION

Specific techniques required; see *Precautions*.

Each 100-mg vial is diluted with 9.9 mL (200 mg with 19.7 mL) of SWFI (10 mg/mL). Further dilution in 50 to 250 mL of D5W or NS for infusion is p referred. May be given through Y-tube or three-way stopcock of infusion set through a free-flowing IV.

Storage:

Discard in 6 to 8 hours if kept at room temperature. Reconstituted solution stable for 72 hours, diluted solution for 24 hours if refrigerated at 4° C (39° F).

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Total dose over 30 to 60 minutes. More rapid rate may cause severe venous irritation.

ACTIONS

An antineoplastic agent. Exact mechanism of action is not known; may inhibit DNA and RNA synthesis. It is an alkylating agent, cell cycle phase nonspecific. Probably localizes in the liver and is excreted in the urine.

INDICATIONS AND USES

Metastatic malignant melanoma. ■ Hodgkin disease. ■ Soft-tissue sarcomas.

Unlabeled uses:

Treatment of malignant pheochromocytoma with cyclophosphamide and vincristine. ■ Treatment of metastatic malignant melanoma with tamoxifen.

CONTRAINDICATIONS

Known hypersensitivity to dacarbazine.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist. ■ Bone marrow suppression is the most common toxicity. ■ Hepatic necrosis has been reported. ■ Consider potential for therapeutic benefit versus risk for toxicity. ■ Use caution in impaired liver and renal function.

Monitor:

Determine absolute patency of vein; a stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. Discontinue injection; use another vein. ■ Monitor bone marrow function, white and RBC count, and platelet count frequently. ■ Nausea and vomiting may be reduced by restricting oral intake of fluid and foods for 4 to 6 hours before administration. Use prophylactic antiemetics. ■ Be alert for signs of bone marrow suppression, bleeding, or infection. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education:

Protect skin surfaces; may cause photosensitive skin reactions. ■ Effective birth control recommended. ■ Report burning or stinging at IV site promptly. ■ See Appendix D, p. 1311.

Maternal/Child:

Category C: safety for use in pregnancy or breast-feeding and in men and women capable of conception not established. ■ Carcinogenic and teratogenic in animals. ■ Discontinue breast-feeding.

Elderly:

Consider age-related organ impairment; toxicity may be increased.

DRUG/LAB INTERACTIONS

Do not administer any **live virus vaccines** to patients receiving antineoplastic drugs. ■ Inhibited by **phenobarbital and phenytoin**. ■ Potentiates **allopurinol.** ■ Effects of dacarbazine may be increased with **ciprofloxacin, isoniazid, fluvoxamine, ketoconazole, miconazole, and norfloxacin**. Effects may be decreased with **carbamazepine, phenobarbital, and rifampin**.

SIDE EFFECTS

Leukopenia and thrombocytopenia may be serious enough to cause death. Alopecia, anaphylaxis, anorexia, facial flushing, facial paresthesias, fever, hepatotoxicity, malaise, myalgia, nausea, skin necrosis, vomiting.

ANTIDOTE

Notify physician of all side effects. Most will be treated symptomatically. Bone marrow suppression may require temporary or permanent withholding of treatment. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. For extravasation, elevate extremity; consider injection of long-acting dexamethasone throughout extravasated tissue. Use a 27- or 25-gauge needle. Apply moist, warm compresses.

DACTINOMYCIN BBW

(dack-tin-oh-**MY**-sin)
Cosmegen
Antineoplastic (antibiotic)
pH 5.5 to 7

USUAL DOSE

Pretreatment:

See Maternal/Child.

Dose will depend on tolerance of the patient, the size and location of the tumor, and the use of other forms of therapy. Calculate each dose carefully before administration. Calculation of the dose for obese or edematous patients should be based on body surface area. The dose intensity per 2-week cycle for adult and pediatric patients should not exceed 15 mcg/kg/day (0.015 mg/kg/day) or 400 to 600 mcg/M^2/day (0.4 to 0.6 mg/M^2/day) for 5 days.

Wilms' tumor, childhood rhabdomyosarcoma, and Ewing's sarcoma:

15 mcg/kg/day for 5 days, not to exceed 0.5 mg/day (500 mcg/day). May be administered in various combinations and schedules with other chemotherapeutic agents.

Metastatic nonseminomatous testicular cancer:

1,000 mcg/M^2 (1 mg/M^2) on Day 1 as part of a combination regimen with cyclophosphamide, bleomycin, vinblastine, and cisplatin.

Gestational trophoblastic neoplasia:

12 mcg/kg/day for 5 days as a single agent or 500 mcg on Days 1 and 2 as part of a combination regimen with etoposide, methotrexate, folinic acid, vincristine, cyclophosphamide, and cisplatin.

PEDIATRIC DOSE

Same as Usual Dose for adults; see Contraindications.

DOSE ADJUSTMENTS

Calculate dose based on body surface area in presence of edema or ascites. ■ Used with other antineoplastic drugs in reduced doses to achieve tumor remission. ■ Reduce dose of dactinomycin and radiation therapy when used concurrently, if either has been used previously, or if previous chemotherapy has been employed. ■ Dose selection should be cautious in the elderly. Consider potential for decreased cardiac, hepatic, and renal function, and concomitant disease or drug therapy; see Elderly.

DILUTION

Specific techniques required; see Precautions. Highly toxic. Both powder and solution must be handled with care. Dilute each 0.5-mg vial with 1.1 mL of preservative-free SWFI (0.5 mg/mL). Reconstituted product is a clear, gold-colored solution. SWFI with preservative (benzyl alcohol or paraben) will cause precipitation. Very corrosive to soft tissue. Use sterile two-needle technique if given by IV injection; one needle to dilute and withdraw and one needle to inject into the vein (rinse with blood or IV solution before removing). May be given by IV injection, through the Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS, or further diluted in one of the above solutions for infusion to a final concentration of 10 mcg/mL or higher.

Filters:

Manufacturer states, “Use of some in-line cellulose ester membrane filters have resulted in loss of potency.” Another source suggests no loss of drug potency with a 5-micron stainless steel depth filter.

Storage:

Store at 25° C (77° F). Protect from light and humidity. Prepared product must be used within 4 hours of initial reconstitution when stored at ambient RT. Discard any unused portion.

COMPATIBILITY

Forms a precipitate with SWFI that contains preservatives. Cellulose ester membrane filters may reduce dose by partial removal of dactinomycin.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

IV injection:

A single dose over 2 to 3 minutes.

IV infusion:

A single dose over 10 to 15 minutes.

ACTIONS

A highly toxic antibiotic antineoplastic agent, cell cycle phase nonspecific. Cytotoxic, it interferes with cell division by binding DNA to slow production of RNA. Found in high concentrations in the kidney, liver, and spleen. Does not penetrate the blood-brain barrier. Minimally metabolized. Elimination half-life is approximately 36 hours. Excreted as unchanged drug in bile and urine.

INDICATIONS AND USES

As part of a combination chemotherapy and/or multimodality regimen for treatment of Wilms’ tumor, childhood rhabdomyosarcoma, Ewing’s sarcoma, and metastatic nonseminomatous testicular cancer. ■ Alone or in combination with other chemotherapeutic agents for the treatment of gestational trophoblastic neoplasia.

Unlabeled uses:

Treatment of osteosarcoma, malignant melanoma, Paget’s disease of the bone.

CONTRAINDICATIONS

Exposure to chickenpox, herpes zoster, known sensitivity to dactinomycin, infants under 6 to 12 months of age.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. Review guidelines before handling, and follow diligently. See Appendix A. ■ For IV use only. Do not administer IM or SC. ■ Highly toxic; both the powder and solution must be handled and administered with care. Inhalation of dust or vapors and contact with skin or mucous membranes, especially those of the eyes, must be avoided. If eye contact occurs, rinse for at least 15 minutes with water, saline or a balanced salt ophthalmic solution and then seek immediate ophthalmologic consultation. If skin contact occurs, remove contaminated clothing and rinse area for 15 minutes. Medical attention should be sought immediately and clothes should be destroyed. ■ Administered by or under the direction of a physician specialist. ■ In general, dactinomycin should not be administered concomitantly with radiation therapy in the treatment of Wilms' tumor unless the benefit outweighs the risk. Hepatomegaly and elevated AST levels have been reported. ■ Hepatic veno-occlusive disease that may be associated with intravascular clotting disorder and multiorgan failure has been reported. Pediatric patients younger than 48 months of age may be at increased risk. ■ May have increased incidence of second primary tumors following treatment with dactinomycin and radiation. Long-term follow-up of cancer survivors is indicated.

Monitor:

Very corrosive to soft tissue; determine absolute patency of vein. If extravasation occurs, severe damage to soft tissue will result. A stinging or burning sensation indicates extravasation; severe cellulitis and tissue necrosis will result. Discontinue injection; use another vein. Close observation and reconstructive surgery consultation are recommended. ■ Monitor renal, hepatic, and bone marrow function frequently. ■ Except for immediate nausea and vomiting, side effects may not appear for 2 to 4 days and may not peak for 1 to 2 weeks. Always observe closely. Use prophylactic antiemetics. ■ If stomatitis, diarrhea, or severe hematopoietic depression appears, discontinue therapy until the patient has recovered. ■ An increased incidence of GI toxicity, bone marrow suppression, and skin and mucosal reactions has been reported when dactinomycin is administered in combination with radiation therapy. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Increased fluid intake and uric acid–lowering drugs (e.g., allopurinol) may be required to reduce uric acid levels. ■ Observe closely for signs of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient.

Patient Education:

Effective birth control recommended. ■ Report burning or stinging at IV site promptly. ■ See Appendix D.

Maternal/Child:

Category D: avoid pregnancy. May produce teratogenic effects on the fetus; use caution in men and women capable of conception. ■ Discontinue breast-feeding. ■ Greater frequency of toxic effects seen in infants. See Contraindications and Precautions.

Elderly:

Response similar to that in younger adults; however, recent studies suggest elderly may be at increased risk for myelosuppression; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Dactinomycin potentiates the effects of **radiation therapy;** use with caution in patients receiving radiation therapy. Reduced doses are indicated with simultaneous use; risk of GI toxicity and myelosuppression increased. ■ Dactinomycin alone may reactivate erythema from **previous radiation therapy.** ■ Do not administer **live virus vaccines** to patients receiving antineoplastic drugs. ■ Inhibits action of **penicillin.** ■ See Dose Adjustments. ■ May interfere with **bioassay procedures** used in determining antibacterial drug levels.

SIDE EFFECTS

Toxic reactions are frequent, may be severe, and may be dose limiting; however, the severity of toxicity varies markedly and is only partly dependent on the dose administered. Abdominal pain, acne, alopecia, anaphylaxis, anorexia, bone marrow suppression (e.g., anemia, aplastic anemia, agranulocytosis, febrile neutropenia, leukopenia, neutropenia, thrombocytopenia), cheilitis, diarrhea, dysphagia, erythema flare-up, erythema multiforme, esophagitis, fatigue, fever, GI ulceration, hypocalcemia, lethargy, liver toxicity (ascites, hepatitis, hepatic failure with reports of death, hepatic veno-occlusive disease, hepatomegaly, and liver function test abnormalities), malaise, myalgia, nausea, pharyngitis, pneumonitis, proctitis, sepsis (including neutropenic sepsis), skin eruptions, ulcerative stomatitis, vomiting.

Post-Marketing:

Stevens-Johnson syndrome, toxic epidermal necrolysis.

ANTIDOTE

Any side effect can result in death. Notify the physician of all side effects. Most will be treated symptomatically. Bone marrow suppression may require withholding dactinomycin until recovery occurs. No specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa [Aranesp], epoetin alfa [Epogen], filgrastim [Neupogen, Zarxio], pegfilgrastim [Neulasta], sargramostim [Leukine]) may be indicated to treat bone marrow toxicity. For extravasation, discontinue immediately and elevate extremity. Apply ice to site four times daily for 3 days. Close observation and reconstructive surgery consultation recommended.

DALBAVANCIN

(**DAL**-ba-**VAN**-sin)
Dalvance
Antibacterial (lipoglycopeptide)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor.

1,500 mg. May be administered as a single dose or as a two-dose regimen with an initial dose of 1,000 mg followed 1 week later by 500 mg. Administer as an infusion over 30 minutes.

DOSE ADJUSTMENTS

Dosage should be adjusted in patients with renal impairment as outlined in the following chart.

Dosage of Dalbavancin in Patients With Renal Impairment		
Estimated CrCl[a]	**Dalbavancin Single-Dose Regimen[b]**	**Dalbavancin Two-Dose Regimen[b]**
≥30 mL/min or on regular hemodialysis	1,500 mg	1,000 mg followed 1 week later by 500 mg
<30 mL/min and not on regular hemodialysis	1,125 mg	750 mg followed 1 week later by 375 mg

[a] As calculated using the Cockcroft-Gault formula.

[b] Administered IV over 30 minutes.

■ No dose adjustment is recommended for patients receiving regularly scheduled hemodialysis, and dalbavancin can be administered without regard to the timing of hemodialysis. ■ No dose adjustment is recommended for patients with mild hepatic impairment (Child-Pugh Class A). ■ Use caution when prescribed for patients with moderate or severe hepatic impairment (Child-Pugh Class B or C). No data are available to determine appropriate dosing in these patients. ■ No dose adjustment based on age or gender; see Elderly.

DILUTION

Available in single-use vials containing 500 mg of dalbavancin as a lyophilized powder. Reconstitute each 500-mg vial with 25 mL of SWFI or D5W. To avoid foaming, alternate between gentle swirling and inversion of the vial until contents are completely dissolved. ***Do not shake.*** Concentration is 20 mg/mL. Solution should be clear and colorless to yellow. Do not use if particulate matter remains. Transfer the required dose to an IV bag or bottle containing D5W. Diluted solution must have a final concentration of 1 mg/mL to 5 mg/mL.

Filters:

Specific information not available.

Storage:

Vials may be stored at CRT. Reconstituted vials and/or fully diluted solutions may be stored at RT or refrigerated at 2° to 8° C (36° to 46° F). Do not freeze. Total time from reconstitution to dilution to administration should not exceed 48 hours.

COMPATIBILITY

Manufacturer states, "Do not co-infuse dalbavancin with other medications or electrolytes. Saline-based infusion solutions may cause precipitation and should not be used. The **compatibility** of reconstituted dalbavancin with IV medications, additives, or substances other than D5W has not been established."

RATE OF ADMINISTRATION

A single dose as an infusion equally distributed over 30 minutes. If a common IV line is used to administer other drugs in addition to dalbavancin, flush the IV line before and after each dalbavancin infusion with D5W. Too-rapid infusion may cause "red-man syndrome," including back pain, flushing of the upper body, pruritus, rash, and/or urticaria. Temporarily stop or slow the infusion as indicated.

ACTIONS

Dalbavancin is a semi-synthetic lipoglycopeptide antibacterial drug. It interferes with cell wall synthesis by binding to the D-alanyl-D-alanine terminus of the stem pentapeptide in nascent cell wall peptidoglycan, thus preventing cross-linking. In vitro, dalbavancin is bactericidal against *Staphylococcus aureus* and *Streptococcus pyogenes* at concentrations similar to those sustained throughout treatment; see Indications. 93% bound to plasma proteins, primarily to albumin. Mean concentrations achieved in skin blister fluid remain above 30 mg/L up to 7 days after dosing. Effective half-life is approximately 346 hours. Excreted in feces and urine as unchanged drug and as a metabolite.

INDICATIONS AND USES

Treatment of adult patients with acute bacterial skin and skin structure infections (ABSSSI) caused by susceptible isolates of designated gram-positive microorganisms, including *Staphylococcus aureus* (both methicillin-susceptible [MSSA] and methicillin-resistant [MRSA] strains).

CONTRAINDICATIONS

Known hypersensitivity to dalbavancin. No data available on cross-reactivity between dalbavancin and other glycopeptides, including vancomycin.

PRECAUTIONS

Serious hypersensitivity (anaphylactic) and skin reactions have been reported. Check history of previous hypersensitivity reactions to glycopeptides (e.g., oritavancin, telavancin, vancomycin). Exercise caution in patients with a history of glycopeptide allergy; cross-sensitivity is possible. ■ Infusion-related reactions have been reported; see Rate of Administration. ■ Specific sensitivity studies are indicated to determine susceptibility of the causative organism to dalbavancin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, dalbavancin should be used to treat only those infections proven or strongly suspected to be caused by bacteria. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported for nearly all systemic antibacterial agents and may range in severity from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with dalbavancin. ■ ALT elevations greater than 3 times the ULN occurred in some patients with normal baseline transaminase levels before treatment.

Monitor:

Obtain baseline SCr. ■ Monitor for S/S of hypersensitivity (e.g., hypotension, rash, urticaria, tightness of the chest, wheezing). ■ Monitor for S/S of an infusion reaction; see Rate of Administration. ■ See Precautions; baseline liver function studies may be indicated.

Patient Education:

Promptly report S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath, wheezing) or an infusion reaction (e.g., back pain, flushing of the upper body, pruritus, rash, and/or urticaria). ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

Use during pregnancy only if the potential benefit outweighs the possible risk to the fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

Consider age-related renal impairment, monitoring of renal function, and dose with caution; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Clinical drug-drug interaction studies have not been conducted. ■ There is minimal potential for drug-drug interactions between dalbavancin and substrates, inhibitors, and inducers of cytochrome P_{450} enzymes.

SIDE EFFECTS

The most common side effects reported are diarrhea, headache, and nausea. Hypersensitivity and/or infusion reactions may be severe. Increased ALT levels (reversible), pruritus, rash, and vomiting were also reported. Many other side effects occurred in fewer than 2% of patients.

Post-Marketing:

Back pain as an infusion-related reaction.

ANTIDOTE

Notify physician of any side effects. Discontinue the drug if indicated. Treat hypersensitivity reactions as indicated (e.g., diphenhydramine, epinephrine, albuterol) and resuscitate as necessary. Temporarily discontinue or slow infusion for infusion-related reactions. Mild cases of CDAD may respond to discontinuation of dalbavancin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Less than 6% of the recommended dose of dalbavancin is removed by hemodialysis.

DANTROLENE SODIUM

(**DAN**-troh-leen **SO**-dee-um)
Dantrium, Revonto ■ Ryanodex
Skeletal muscle relaxant (direct acting)
pH 9.5 ■ 10.3

USUAL DOSE

In patients known to be susceptible to malignant hyperthermia (MH), oral dantrolene may be used prophylactically preoperatively. Oral or IV therapy should be used postoperatively for 1 to 3 days following IV treatment for MH crisis. Postoperative dosing is indicated after emergency treatment to prevent recurrence of the manifestations of MH.

Prophylactic dose:

Dantrium, Revonto:

2.5 mg/kg as an infusion. Begin administration 1¼ hours before anesthesia, and administer over 1 hour. Oral dantrolene may be used.

Ryanodex:

2.5 mg/kg as an IV injection over at least 1 minute. Begin administration 1¼ hours before surgery. If surgery is prolonged, administer additional individualized doses during anesthesia and surgery as needed.

All Formulations:

Avoid agents that trigger MH (e.g., general anesthetics and depolarizing neuromuscular blocking agents [succinylcholine]).

Therapeutic or emergency dose:

All Formulations:

Discontinue all anesthetic agents at the first sign of a malignant hyperthermia reaction. Administration of 100% oxygen is recommended.

1 mg/kg of body weight as an initial dose as a rapid IV push. Repeat as necessary until symptoms subside or a cumulative dose of 10 mg/kg is reached. Entire regimen may be repeated if symptoms reappear. Dose required depends on degree of susceptibility to

malignant hyperthermia, length of time of exposure to triggering agent, and time lapse between onset of crisis and beginning of treatment.

Post-crisis follow-up:

An oral dose of 4 to 8 mg/kg/day for 1 to 3 days to prevent recurrences. If oral dosing not feasible, begin IV dose at 1 mg/kg and individualize by increasing based on patient response.

PEDIATRIC DOSE

Prophylactic, therapeutic, and post-crisis follow-up doses are the same as for adults; see Maternal/Child.

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly. Reduced doses may be indicated based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Dantrium, Revonto:

Each 20 mg must be diluted with 60 mL SWFI without a bacteriostatic agent. Shake until solution is clear. May be administered through a Y-tube or three-way stopcock of infusion tubing. If large volumes will be used, transfer to plastic infusion bags; do not use glass bottles; see Compatibility.

Ryanodex:

Reconstitute each 250-mg vial with 5 mL of SWFI without a bacteriostatic agent. Shake the vial to ensure an orange-colored uniform suspension. Do not reconstitute with D5W or NS; see Compatibility. May be administered directly into an indwelling catheter or through a Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS.

Storage:

All Formulations:

Store undiluted vials at CRT and protect from light. Store diluted solution at CRT and protect from direct light. Discard after 6 hours.

COMPATIBILITY

Dantrium, Revonto:

Manufacturer states, “D5W, NS, and acidic solutions are **not compatible** and should not be used.” May form a precipitate with glass bottles; use of plastic IV bags recommended.

Ryanodex:

Do not dilute or transfer the reconstituted suspension to another container to infuse the product.

RATE OF ADMINISTRATION

Prophylactic dose:

Dantrium, Revonto:
A single dose as an infusion distributed over 1 hour.

Ryanodex:
A single dose as an IV injection over at least 1 minute. If administering into an indwelling catheter without a free-flowing IV, flush line after administration of Ryanodex to ensure there is no residual drug left in the catheter.

Therapeutic or emergency dose:

All Formulations:
Each single dose should be given by rapid continuous IV push. Follow immediately with subsequent doses as indicated.

ACTIONS

A direct-acting skeletal muscle relaxant. Inhibits excitation-contraction coupling by interfering with the release of the calcium ion from the sarcoplasmic reticulum to reverse the physiologic cause of malignant hyperthermia and produce relaxation. The addition of dantrolene to the “triggered” malignant hyperthermic muscle cell may re-establish a normal level of ionized calcium in the myoplasm. Physiologic, metabolic, and biochemical changes associated with the malignant hyperthermia crisis may be reversed or attenuated. Has no appreciable effect on cardiovascular or respiratory function. Onset of action is prompt. Half-life of **Dantrium** and **Revonto** is 4 to 8 hours. Half-life of **Ryanodex** is 8.5 to 11.4 hours. Metabolized in the liver and excreted in urine. Readily crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Treatment of malignant hyperthermia in conjunction with appropriate supportive measures. ■ Prevention of malignant hyperthermia in patients at high risk.

CONTRAINDICATIONS

None.

PRECAUTIONS

Use caution in patients with impaired pulmonary or cardiac function or history of liver disease. ■ Discontinue all anesthetic agents immediately when onset of malignant hyperthermia is recognized. Administration of 100% oxygen is recommended. ■ Hepatotoxicity has been reported with oral dantrolene. ■ Not indicated for use in patients with neuroleptic malignant syndrome (NMS).

Monitor:

S/S of malignant hyperthermia crises include central venous desaturation, cyanosis and mottling of the skin, hypercarbia, increased utilization of anesthesia circuit carbon dioxide absorber, metabolic acidosis, skeletal muscle rigidity, tachycardia, tachypnea and, in many cases, fever. ■ Monitor ECG, vital signs, electrolytes, and urine output continuously. ■ Oxygen needs are increased. ■ Manage metabolic acidosis. ■ Institute cooling measures. ■ Diuretics may be required to prevent or treat late kidney injury due to myoglobinuria. Consider amount of mannitol present in **Dantrium** or **Revonto** formulations. (**Ryanodex** does not contain a sufficient amount of mannitol to maintain diuresis.) ■ Confirm absolute patency of vein; avoid extravasation. High pH may cause tissue necrosis. ■ Associated with skeletal muscle weakness; see Patient Education. ■ Ensure adequate ventilation; has been associated with dyspnea, respiratory muscle weakness, and decreased inspiratory capacity. ■ Assess patients for difficulty swallowing and choking. ■ Monitor hepatic function, including ALT, AST. ■ Somnolence and dizziness may persist for up to 48 hours postdose. Ambulate with assistance.

Patient Education:

May experience decreased grip strength, weakness in leg muscles, and light-headedness postoperatively. May persist for 48 hours. ■ Request assistance for ambulation. ■ Use caution when eating; choking and difficulty swallowing have been reported on day of administration. ■ Avoid alcohol and other CNS depressants (e.g., diazepam [Valium]). ■ Avoid tasks that require alertness. ■ Promptly report bloody or tarry stools, itching, jaundice (yellow color) of eyes and skin, or skin rash.

Maternal/Child:

Category C: embryocidal in animal studies. Use during pregnancy only if potential benefit justifies potential risk to the fetus. ■ Discontinue breast-feeding. ■ Safety and effectiveness for use in pediatric patients have been established. Dose is the same as for adults.

Elderly:

Differences in responses between the elderly and younger patients have not been identified. Dose selection should be cautious; see Dose Adjustments.

DRUG/LAB INTERACTIONS

All Formulations:

Avoid concurrent use of **calcium channel blockers and dantrolene**. Cardiovascular collapse, arrhythmias, and hyperkalemia have been reported. ■ Ability to bind to plasma proteins inhibited by **warfarin**; increased by **tolbutamide**.

Dantrium and Revonto:

May potentiate **vecuronium**-induced neuromuscular blockade.

Ryanodex:

May potentiate the neuromuscular block when given with **muscle relaxants**. ■ May potentiate the effects of **antipsychotic agents** (e.g., pimozide, clozapine) and **antianxiety agents** (e.g., diazepam) on the central nervous system. ■ Concomitant use of **sedative agents** may increase the risk of somnolence and dizziness.

SIDE EFFECTS

Dizziness, drowsiness, loss of grip strength, and weakness in the legs are most common. Other reported side effects include erythema, hypersensitivity reactions (including anaphylaxis), injection site reactions, nausea, pulmonary edema, thrombophlebitis, tissue necrosis secondary to extravasation, urticaria.

ANTIDOTE

No specific antidote is available or needed when used correctly. Notify physician and initiate supportive measures (ensure adequate airway and ventilation, monitor ECG) in overdosage. Large amounts of IV fluids may be needed to prevent crystalluria. Treat anaphylaxis and resuscitate as necessary. Value of dialysis in overdose is not known.

DAPTOMYCIN

(**dap**-toe-**MY**-sin)
Cubicin, Cubicin RF
Antibacterial (cyclic lipopeptide)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor.

All Formulations

Dosages range between 4-10 mg/kg/day, depending on site of infection. Safety data for use more than 28 days is limited.

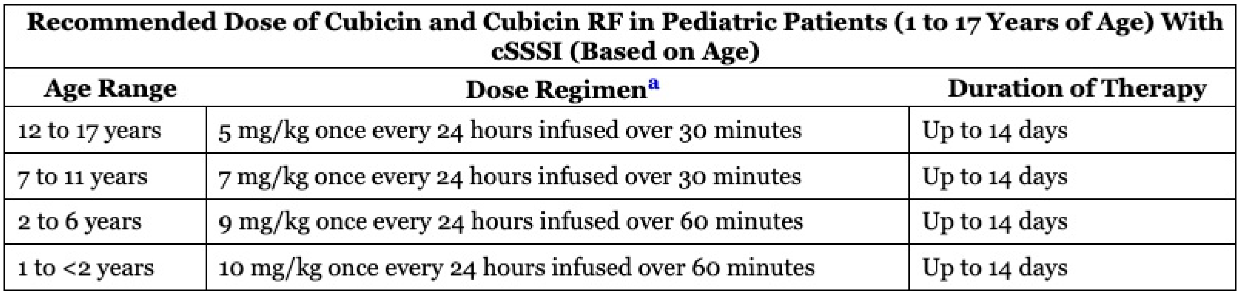
PEDIATRIC DOSE

Cubicin and Cubicin RF:

Merck & Co., Inc. has exclusive marketing rights. Cubicin and Cubicin RF are the only formulations approved for pediatric indications.

Complicated skin and skin structure infections (cSSSI):

Dose is based on age according to the following chart.



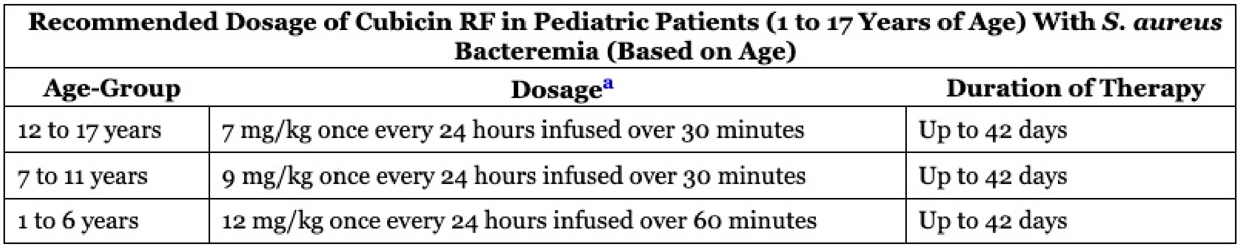
Recommended Dose of Cubicin and Cubicin RF in Pediatric Patients (1 to 17 Years of Age) With cSSSI (Based on Age)

Age Range	Dose Regimen[a]	Duration of Therapy
12 to 17 years	5 mg/kg once every 24 hours infused over 30 minutes	Up to 14 days
7 to 11 years	7 mg/kg once every 24 hours infused over 30 minutes	Up to 14 days
2 to 6 years	9 mg/kg once every 24 hours infused over 60 minutes	Up to 14 days
1 to <2 years	10 mg/kg once every 24 hours infused over 60 minutes	Up to 14 days

[a] Recommended dose regimen is for pediatric patients with normal renal function. Dose adjustment for pediatric patients with renal impairment not established.

Cubicin RF:

Staphylococcus aureus bloodstream infections (bacteremia) in pediatric patients (1 to 17 years of age): Dose is based on age according to the following chart.



Recommended Dosage of Cubicin RF in Pediatric Patients (1 to 17 Years of Age) With *S. aureus* Bacteremia (Based on Age)

Age-Group	Dosage[a]	Duration of Therapy
12 to 17 years	7 mg/kg once every 24 hours infused over 30 minutes	Up to 42 days
7 to 11 years	9 mg/kg once every 24 hours infused over 30 minutes	Up to 42 days
1 to 6 years	12 mg/kg once every 24 hours infused over 60 minutes	Up to 42 days

[a] Recommended dosage is for pediatric patients (1 to 17 years of age) with normal renal function. Dosage adjustment for pediatric patients with renal impairment has not been established.

DOSE ADJUSTMENTS

All Formulations:

No dose adjustment is required in adult patients with creatinine clearance 30 mL/min or higher. ■ In patients with CrCl less than 30 mL/min, including patients undergoing hemodialysis or CAPD, administer a single dose (4 or 6 mg/kg) every 48 hours. If possible, administer dose following completion of hemodialysis on hemodialysis days. ■ Dose adjustment for pediatric patients with renal impairment not established. ■ No specific dose adjustments required based on age, gender, obesity, or mild to moderate hepatic impairment. Has not been studied in patients with severe hepatic impairment.

DILUTION

All Formulations Except Cubicin RF

Available in 350-mg and 500-mg single-dose vials. Reconstitute each 350-mg vial with 7 mL of NS and each 500-mg vial with 10 mL of NS. Slowly direct NS to vial sides

(50 mg/mL). Use of a transfer needle that is 21 gauge or smaller in diameter or a needleless device is recommended. Ensure wetting of entire daptomycin product. Allow vial to stand for 10 minutes, then gently rotate to ensure complete dilution. ***To minimize foaming, avoid vigorous agitation or shaking during or after reconstitution.*** Freshly reconstituted solutions range in color from pale yellow to light brown. Slowly remove the appropriate amount of the 50 mg/mL solution from the vial using a needle that is 21 gauge or smaller in diameter.

Adults:

May be administered as a 50 mg/mL reconstituted solution or may be further diluted with 50 mL of NS before administration and given as an infusion.

Pediatric patients (30-minute infusion):

Further dilute each dose to be administered over 30 minutes in 50 mL NS.

Pediatric patients (60-minute infusion):

Further dilute each dose to be administered over 60 minutes in 25 mL NS.

Cubicin RF

Reconstitute each single-dose 500-mg vial by directing 10 mL of ***SWFI or BWFI*** to vial sides (50 mg/mL). Use of a transfer needle that is 21 gauge or smaller in diameter is recommended. ***DO NOT*** use saline-based diluents for reconstitution, because this will result in a hyperosmotic solution that may result in infusion site reactions if the reconstituted product is administered as an IV injection over a period of 2 minutes. Slowly remove the appropriate amount of 50 mg/mL solution from the vial using a needle that is 21 gauge or smaller in diameter.

Adults:

May be administered as a 50 mg/mL reconstituted solution or may be further diluted with 50 mL of NS before administration and given as an infusion.

Pediatric patients 7 to 17 years of age (30-minute infusion):

Further dilute each dose to be administered over 30 minutes in 50 mL NS.

Pediatric patients 1 to 6 years of age (60-minute infusion):

Further dilute each dose to be administered over 60 minutes in 25 mL NS.

Filters:

No data available from manufacturer.

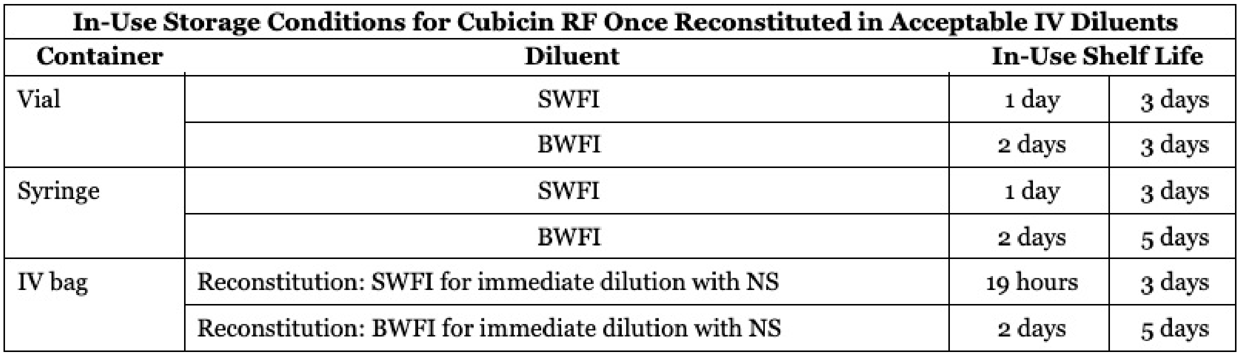
Storage:

Cubicin and generics:

Refrigerate unopened vials at 2° to 8° C (36° to 46° F). Both reconstituted and diluted solutions are stable for 12 hours at RT or up to 48 hours refrigerated. The combined time (vial and infusion bag) at RT should not exceed 12 hours. Combined refrigeration time (vial and infusion bag) should not exceed 48 hours.

Cubicin RF:

In-use storage conditions for Cubicin RF are outlined in the following chart.



In-Use Storage Conditions for Cubicin RF Once Reconstituted in Acceptable IV Diluents			
Container	**Diluent**	**In-Use Shelf Life**	
Vial	SWFI	1 day	3 days
	BWFI	2 days	3 days
Syringe	SWFI	1 day	3 days
	BWFI	2 days	5 days
IV bag	Reconstitution: SWFI for immediate dilution with NS	19 hours	3 days
	Reconstitution: BWFI for immediate dilution with NS	2 days	5 days

All formulations:

Discard unused portion of vial.

COMPATIBILITY

All Formulations:

Additives or other medications should not be added to daptomycin single-use vials or infusion bags, or infused simultaneously through the same intravenous line. If the same intravenous line is used for sequential infusion of several different drugs, the line should be flushed with a **compatible** infusion solution before and after infusion with daptomycin. ■ **Cubicin and generics** in the vial are **compatible** with NS, but **Cubicin RF in the vial** is **incompatible** and should **not** be reconstituted with NS because this will result in a hyperosmotic solution that may result in infusion site reactions if administered as the 2-minute IV injection. **All formulations** are **incompatible** with dextrose-containing diluents. ■ **All formulations:** Do not use in conjunction with ReadyMED® elastomeric infusion pumps; an **incompatibility** occurs because of an impurity leaching from this pump system into the daptomycin solution.

Reconstituted Cubicin:

Compatible with NS and LR.

Reconstituted Cubicin RF:

Compatible with NS, SWFI, and BWFI.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer for **Cubicin and generics**; consult a pharmacist.

RATE OF ADMINISTRATION

All Formulations

See Compatibility. Flushing of the IV line before and after infusion may be indicated.

Injection:

Adults:
A single dose properly reconstituted and administered over 2 minutes.

Infusion:

Adults:
A single dose properly diluted and administered over 30 minutes.

Pediatric patients 7 to 17 years of age:
A single dose properly diluted and administered as an IV infusion over 30 minutes. Maintain infusion rate at 1.67 mL/min.

Pediatric patients 1 to 6 years of age:
A single dose properly diluted and administered as an IV infusion over 60 minutes. Maintain infusion rate at 0.42 mL/min.

Do not administer as an injection in pediatric patients.

ACTIONS

Daptomycin is a cyclic lipopeptide antibacterial agent. Binds to bacterial cell membranes and causes a rapid depolarization of the membrane potential. Loss of the membrane potential leads to inhibition of protein, DNA, and RNA synthesis, which results in bacterial cell death. Exhibits bactericidal activity against aerobic gram-positive bacteria and has been shown to retain potency against antibiotic-resistant, gram-positive bacteria, including isolates resistant to methicillin. Cross-resistance between daptomycin and other antibacterial agents has not been reported. Highly protein bound, primarily to albumin. Site of metabolism has not been identified. Half-life is approximately 7 to 9 hours. Is excreted primarily by the kidney. A small fraction is excreted through the feces. Secreted in breast milk.

INDICATIONS AND USES

All formulations:

Treatment of adult patients with complicated skin and skin structure infections caused by susceptible strains of several aerobic gram-positive microorganisms. ■ Treatment of adults with *Staphylococcus aureus* bloodstream infections (bacteremia), including adult patients with right-sided infective endocarditis caused by methicillin-susceptible and methicillin-resistant isolates.

Cubicin and Cubicin RF:

Treatment of pediatric patients (1 to 17 years of age) with complicated skin and skin structure infections caused by susceptible strains of several aerobic gram-positive microorganisms. ■ Treatment of pediatric patients (1 to 17 years of age) with *Staphylococcus aureus* bloodstream infections (bacteremia).

Limitations of use:

All formulations:

Daptomycin is not indicated for treatment of left-sided infective endocarditis due to *S. aureus* and has not been studied in patients with prosthetic valve endocarditis. ■ **Not** indicated for treatment of pneumonia. ■ Not recommended in pediatric patients under 1 year of age; see Maternal/Child.

CONTRAINDICATIONS

Known hypersensitivity to daptomycin.

PRECAUTIONS

All formulations:

C/S indicated to determine susceptibility of causative organism to daptomycin. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, daptomycin should be used to treat only those infections that are proven or strongly suspected to be caused by susceptible bacteria. ■ Combination therapy may be clinically indicated if the documented or presumed pathogens include gram-negative or anaerobic organisms. ■ Eosinophilic pneumonia has been reported. Onset is usually 2 to 4 weeks after initiation of daptomycin and improves when therapy is discontinued. Patient may present with fever, dyspnea with hypoxic respiratory insufficiency, and diffuse pulmonary infiltrates or organizing pneumonia. ■ Superinfection caused by the overgrowth of nonsusceptible organisms may occur with antibiotic use. Treat as indicated. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with daptomycin. ■ Myopathy (defined as muscle aching or muscle weakness in conjunction with increases in creatine phosphokinase [CPK] values to greater than 10 times the ULN) has been reported. Rhabdomyolysis with or without acute renal failure has been reported. ■ Cases of peripheral neuropathy have been reported. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. ■ In clinical trials, decreased efficacy was observed in patients with moderate baseline renal impairment (CrCl less than 50 mL/min).

Monitor:

All formulations:

Obtain baseline and weekly SCr, BUN, and CPK levels. Patients who received recent prior or concomitant therapy with an HMG-CoA reductase inhibitor, patients with renal insufficiency, and patients who develop unexplained elevations in CPK while receiving daptomycin should be monitored more frequently. See Precautions and Antidote. ■ Monitor for S/S of hypersensitivity reactions (e.g., dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ Monitor for the development of muscle pain or weakness, particularly in the distal extremities. ■ Monitor for S/S of neuropathy and consider discontinuation. ■ Repeat blood cultures indicated in patients with persisting or relapsing *S. aureus* infection or poor clinical response. MIC (minimum inhibitory concentration) susceptibility testing and diagnostic evaluation to rule out sequestered foci of infection may be indicated. Surgical intervention (e.g., débridement, removal of prosthetic device) and/or consideration of a change in antibacterial regimen may be required. ■ Monitor for S/S of eosinophilic pneumonia (e.g., cough, fever, difficulty breathing, shortness of breath, diffuse pulmonary infiltrates or organizing pneumonia). Treatment with systemic steroids is recommended.

Patient Education:

All formulations:

Review side effects with physician. Promptly report muscle pain or weakness, S/S of a hypersensitivity reaction (e.g., hives, rash, shortness of breath or troubled breathing, swelling of eyelids, lips, or face), S/S of neuropathy (e.g., tingling or numbness, especially in the forearm or lower leg), or new or worsening cough, breathlessness, or fever. ■ Review medications (prescription and nonprescription) with health care provider. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment.

Maternal/Child:

All formulations:

Use during pregnancy only if clearly needed. ■ Use caution during breastfeeding. Is present in breast milk. ■ Safety and effectiveness of **Cubicin and Cubicin RF** in pediatric patients from 1 to 17 years of age for treatment of cSSSI and of **Cubicin RF** in pediatric patients from 1 to 17 years of age for treatment of *S. aureus* bloodstream infections (bacteremia) have been established. Avoid use of daptomycin in pediatric patients younger than 1 year of age. Animal studies suggest risk of potential effects on muscular, neuromuscular, and/or nervous systems (either peripheral and/or central). **Cubicin RF** has not been studied in pediatric patients with other bacterial infections.

Elderly:

All formulations:

Lower clinical success rates were seen in patients 65 years of age or older. In addition, adverse events were more common in this age-group. Consider age-related renal impairment. See Dose Adjustment.

DRUG/LAB INTERACTIONS

All formulations:

In vitro synergistic interactions occurred with **aminoglycosides, beta-lactam antibiotics, and rifampin** against some isolates of staphylococci and enterococci, including some methicillin-resistant *Staphylococcus aureus* (MRSA) isolates and some vancomycin-resistant enterococci isolates. ■ Has been administered with **warfarin.** Does not appear to affect the pharmacokinetics of either drug. However, daptomycin can cause a significant concentration-dependent false prolongation of PT and elevation of INR when certain recombinant thromboplastin reagents are used for the assay. This drug-lab interaction can be minimized by drawing specimens for PT/INR near the time of trough plasma concentrations of daptomycin. Evaluation of PT/INR using an alternative method may be required. Evaluate for other causes of abnormally elevated PT/INR results. ■ **HMG-CoA reductase inhibitors** may cause myopathy, which is manifested as muscle pain or weakness associated with elevated levels of CPK and possible rhabdomyolysis. Consider temporarily suspending the use of HMG-CoA reductase inhibitors in patients receiving daptomycin.

SIDE EFFECTS

Adult cSSSI patients:

The most frequently reported side effects were abnormal liver function tests, diarrhea, dizziness, dyspnea, elevated CPK, headache, hypotension, rash, and urinary tract infections.

Pediatric cSSSI patients:

The most frequently reported side effects included abdominal pain, diarrhea, elevated CPK, fever, headache, pruritus, and vomiting.

Adult *S. aureus* bacteremia/endocarditis patients:

The most frequently reported side effects were abdominal pain, bacteremia, chest pain, edema, elevated CPK, hypertension, insomnia, pharyngolaryngeal pain, pruritus, sepsis, and sweating.

Pediatric *S. aureus* bacteremia patients:

Elevated CPK and vomiting were the most frequently reported side effects.

All patients:

Muscle pain or weakness, rhabdomyolysis (with or without renal failure), and peripheral neuropathy have been reported rarely. See Precautions. Hypersensitivity reactions including anaphylaxis, difficulty swallowing, hives, pruritus, shortness of breath, and truncal erythema have been reported. Other reactions have been reported in fewer than 1% of study patients. See manufacturer's literature.

Post-Marketing:

Anaphylaxis; anemia; angioedema; CDAD; cough; difficulty swallowing; drug rash with eosinophilia and systemic symptoms (DRESS); eosinophilic pneumonia; fever; hives; nausea and vomiting; organizing pneumonia; peripheral neuropathy; platelet count decreased; pulmonary eosinophilia; pruritus; serious skin reactions, including Stevens-Johnson syndrome, vesiculobullous rash, and acute generalized exanthematous pustulosis; renal disorders, including acute kidney injury, renal insufficiency, and renal failure; rhabdomyolysis; shortness of breath; thrombocytopenia; truncal erythema; and visual disturbances.

ANTIDOTE

Notify physician of any side effects. Discontinue drug in patients with unexplained S/S of myopathy in conjunction with CPK elevation greater than 1,000 units/L (approximately 5 times the upper limit of normal) or in patients without reported symptoms who have marked elevation in CPK, with levels of greater than 2,000 units/L (equal to or greater than 10 times the ULN). Discontinue daptomycin at the first sign of eosinophilic pneumonia. Treatment with systemic steroids is recommended. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Discontinue daptomycin and treat hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Approximately 15% of daptomycin is removed during a 4-hour hemodialysis run. Approximately 11% is recovered over 48 hours with peritoneal dialysis. Use of a high-flux dialysis membrane may increase the amount of drug removal. Resuscitate as necessary.

DARATUMUMAB

(**DAR**-a-**TOOM**-ue-mab)
Darzalex
Monoclonal antibody
Antineoplastic
pH 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting and baseline studies required; see Monitor and Precautions.

Premedication:

To reduce the risk of infusion reactions, administer premedications 1 to 3 hours before every infusion of daratumumab as outlined below:

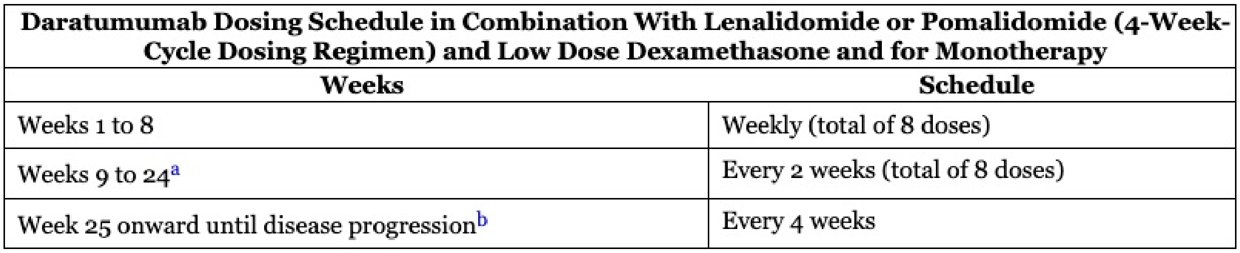
- **Corticosteroid** (intermediate-acting or long-acting)
  - **Monotherapy:** Methylprednisolone 100 mg or equivalent administered IV. After the second infusion, the dose of corticosteroid may be reduced (oral or IV methylprednisolone 60 mg).
  - **Combination therapy:** Administer 20 mg dexamethasone (or equivalent) before every daratumumab infusion. When dexamethasone is the background regimen–specific corticosteroid, the dexamethasone treatment dose will instead serve as premedication on daratumumab infusion days. Dexamethasone is given IV before the first daratumumab infusion. Oral

administration may be considered before subsequent infusions. Additional background regimen-specific corticosteroids (e.g., prednisone) should not be taken on daratumumab infusion days when patients receive dexamethasone (or equivalent) as a premedication.

- **Antipyretic** (oral acetaminophen 650 to 1000 mg)
- **Antihistamine** (oral or IV diphenhydramine 25 to 50 mg or equivalent)

Monotherapy and combination therapy with lenalidomide or pomalidomide and low-dose dexamethasone (4-week-cycle regimen):

The recommended dose of daratumumab is 16 mg/kg actual body weight administered as an infusion according to the dosing schedule outlined in the following chart.



Daratumumab Dosing Schedule in Combination With Lenalidomide or Pomalidomide (4-Week-Cycle Dosing Regimen) and Low Dose Dexamethasone and for Monotherapy

Weeks	Schedule
Weeks 1 to 8	Weekly (total of 8 doses)
Weeks 9 to 24[a]	Every 2 weeks (total of 8 doses)
Week 25 onward until disease progression[b]	Every 4 weeks

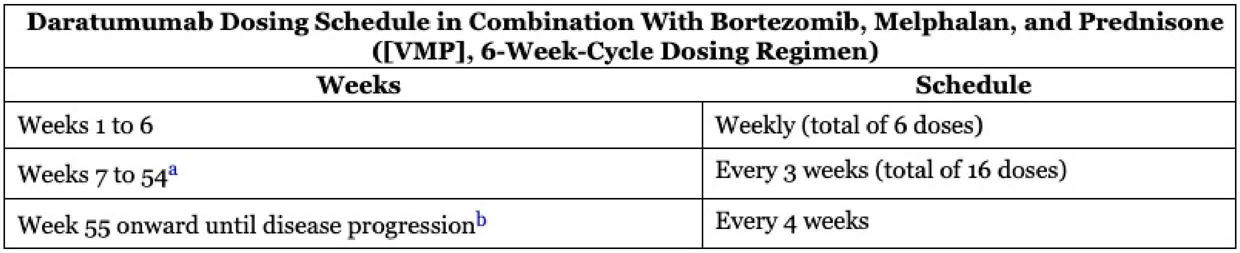
[a] First dose of the every-2-week dosing schedule is given at Week 9.

[b] First dose of the every-4-week dosing schedule is given at Week 25.

For the dosing instructions of combination agents administered with daratumumab, see manufacturer's prescribing information.

Daratumumab in combination with bortezomib, melphalan, and prednisone (6-week-cycle regimen) for patients ineligible for autologous stem cell transplant (ASCT):

The recommended dose is 16 mg/kg actual body weight administered as an infusion according to the dosing schedule outlined in the following chart.



Daratumumab Dosing Schedule in Combination With Bortezomib, Melphalan, and Prednisone ([VMP], 6-Week-Cycle Dosing Regimen)

Weeks	Schedule
Weeks 1 to 6	Weekly (total of 6 doses)
Weeks 7 to 54[a]	Every 3 weeks (total of 16 doses)
Week 55 onward until disease progression[b]	Every 4 weeks

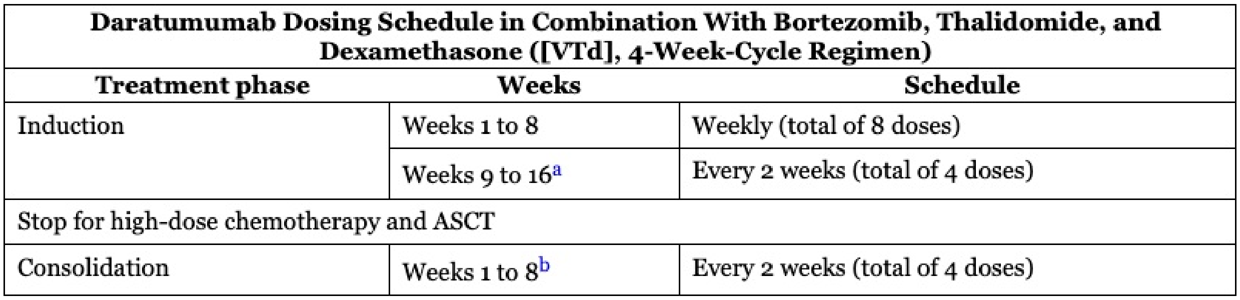
[a] First dose of the every-3-week dosing schedule is given at Week 7.

[b] First dose of the every-4-week dosing schedule is given at Week 55.

For dosing instructions of combination agents administered with daratumumab, see manufacturer's prescribing information.

Daratumumab in combination with bortezomib, thalidomide, and dexamethasone (4-week-cycle regimen) for patients eligible for autologous stem cell transplant:

The recommended dose is 16 mg/kg actual body weight administered as an infusion according to the dosing schedule outlined in the following chart.



Daratumumab Dosing Schedule in Combination With Bortezomib, Thalidomide, and Dexamethasone ([VTd], 4-Week-Cycle Regimen)

Treatment phase	Weeks	Schedule
Induction	Weeks 1 to 8	Weekly (total of 8 doses)
	Weeks 9 to 16[a]	Every 2 weeks (total of 4 doses)
Stop for high-dose chemotherapy and ASCT		
Consolidation	Weeks 1 to 8[b]	Every 2 weeks (total of 4 doses)

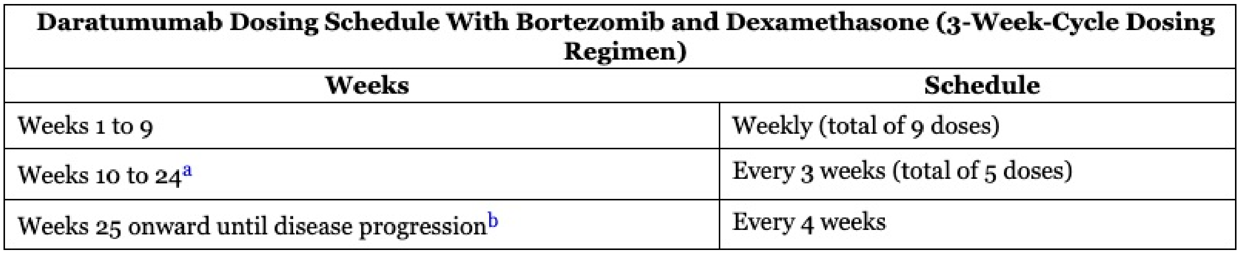
[a] First dose of the every-2-week dosing schedule is given at Week 9.

[b] First dose of the every-2-week dosing schedule is given at Week 1 upon re-initiation of treatment following ASCT.

For dosing instructions of combination agents administered with daratumumab, see manufacturer's prescribing information.

Combination therapy with bortezomib and dexamethasone (3-week-cycle regimen):

The recommended dose of daratumumab is 16 mg/kg actual body weight administered as an infusion according to the dosing schedule outlined in the following chart.



Daratumumab Dosing Schedule With Bortezomib and Dexamethasone (3-Week-Cycle Dosing Regimen)

Weeks	Schedule
Weeks 1 to 9	Weekly (total of 9 doses)
Weeks 10 to 24[a]	Every 3 weeks (total of 5 doses)
Weeks 25 onward until disease progression[b]	Every 4 weeks

[a] First dose of the every-3-week dosing schedule is given at Week 10.

[b] First dose of the every-4-week dosing schedule is given at Week 25.

For the dosing instruction of the combination agents administered with daratumumab, see manufacturer's prescribing information.

Missed daratumumab doses:

If a planned dose is missed, administer as soon as possible and adjust the dosing schedule accordingly, maintaining the treatment interval.

Postinfusion medication:

To reduce the risk of delayed infusion reactions, administer postinfusion medications as outlined below:

- **Monotherapy:** Administer an oral corticosteroid (20 mg methylprednisolone or equivalent of an intermediate-acting or long-acting corticosteroid in accordance with local standards) on each of the 2 days following all daratumumab infusions and beginning the day after the infusion.
- **Combination therapy:** Consider administering low-dose oral methylprednisolone (less than or equal to 20 mg) or equivalent the day after the daratumumab infusion. However, if a background regimen-specific corticosteroid (e.g., dexamethasone, prednisone) is administered the day after the daratumumab infusion, additional postinfusion medications may not be needed.
- For patients with a history of chronic obstructive pulmonary disease, consider prescribing postinfusion short-acting and long-acting bronchodilators and inhaled corticosteroids after the first four infusions. These additional inhaled postinfusion medications may be discontinued if no major infusion reactions occur.

Herpes zoster reactivation prophylaxis:

Initiate within 1 week of starting daratumumab and continue for 3 months following treatment.

DOSE ADJUSTMENTS

No dose reductions of daratumumab are recommended. Dose delays may be required to allow recovery of blood cell counts in the event of hematologic toxicity; see Precautions, Monitor, and Antidote. ■ For information concerning dose adjustments for drugs given in combination with daratumumab, see manufacturer's prescribing information. ■ Interrupt daratumumab infusion for infusion reactions of any severity and manage symptoms. ■ Upon resolution of Grade 1 or 2 (mild to moderate) infusion reactions, resume the infusion at no more than half the rate at which the reaction occurred. If no further reactions occur, infusion rate escalation may resume at increments and intervals as appropriate; see Rate of Administration. ■ Once symptoms of a Grade 3 (severe) reaction resolve, consider restarting the infusion at no more than half the rate at which the reaction occurred. If no further reactions occur, resume rate escalation at increments and intervals as appropriate; see Rate of Administration. ■ If Grade 3 reactions occur for a second time, repeat the protocol as outlined. ■ Permanently discontinue daratumumab if a third Grade 3 or a Grade 4 (life-threatening) reaction occurs. ■ No dose adjustment required for age, gender, renal impairment, or mild or moderate hepatic impairment.

DILUTION

Available as a 100 mg/5 mL or a 400 mg/20 mL single-dose vial (20 mg/mL). Calculate the dose (mg) based on actual body weight, total volume (mL) of daratumumab solution required, and the number of vials required using the following calculations:

Dose (mg) = Weight (kg) × Dose (mg/kg)

# of vials required = Dose (mg) ÷ 100 (400) mg/vial

# of mL required = Dose (mg) ÷ 20 mg/mL

For a 60-kg patient: [(60 kg) × (16 mg/kg)] ÷ 100 (400) mg/vial = 9.6 vials of the 100-mg/vial solution and 2.4 vials of the 400-mg/vial solution. After patient is weighed and appropriate dose is calculated, remove sufficient vials from the refrigerator. Aseptic technique imperative. Solution should be colorless to pale yellow. Do not use if opaque particles, discoloration, or other foreign particles are present. Withdraw the calculated dose (48 mL in both of the previous examples) from the required number of vials. This calculated dose must be further diluted in NS. Withdraw and discard a volume of NS equal to the calculated volume of daratumumab from a bag/container of NS based on the chart in Rate of Administration (1,000 or 500 mL) and slowly add daratumumab solution. Gently invert the bag/bottle to mix the solution. Infusion bags/containers must be made of polyvinylchloride (PVC), polypropylene (PP), polyethylene (PE), or polyolefin blend (PP+PE).

Filters:

Must be administered through an infusion set with a flow regulator and an in-line, sterile, nonpyrogenic, low–protein binding polyethersulfone (PES) filter (pore size 0.22 or 0.2 micrometer). Polyurethane (PU), polybutadiene (PBD), PVC, PP, or PE administration sets must be used.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F) in original carton to protect from light. Do not freeze or shake. The diluted product should be used immediately but may be stored for up to 24 hours if refrigerated and protected from light. Do not freeze. Bring to room temperature before infusion and use immediately. Diluted solution may be kept at RT for a maximum of 15 hours (including infusion time). Diluted solution may develop very small, translucent to white proteinaceous particles because daratumumab is a protein. Do not use if opaque particles, discoloration, or other foreign particles are present. Discard any unused product remaining in vials.

COMPATIBILITY

Manufacturer states, “Do not infuse concomitantly in the same IV line with other agents.” **Compatible** only with IV bags/containers of polyvinylchloride (PVC), polypropylene (PP), polyethylene (PE), or polyolefin blend (PP+PE); filters of polyethersulfone (PES); and administration sets of polyurethane (PU), polybutadiene (PBD), PVC, PP, or PE.

RATE OF ADMINISTRATION

For IV infusion only. Interrupt daratumumab infusion for infusion reactions of any severity and manage symptoms. To facilitate administration, the first 16 mg/kg dose at Week 1 may be split over 2 consecutive days (i.e., 8 mg/kg on Day1 and 8 mg/kg on Day

2, respectively). See the following chart for daratumumab infusion rates.

Infusion Rates for Daratumumab (16mg/kg) Administration				
	Dilution Volume	**Initial Rate (First Hour)**	**Rate Increment**[a]	**Maximum Rate**
Week 1 Infusion				
Option 1 (Single-dose infusion)				
Week 1, Day 1 (16 mg/kg)	1,000 mL	50 mL/hr	50 mL/hr every hour	200 mL/hr
Option 2 (Split-dose infusion)				
Week 1, Day 1 (8 mg/kg)	500 mL	50 mL/hr	50 mL/hr every hour	200 mL/hr
Week 1, Day 2 (8 mg/kg)	500 mL	50 mL/hr	50 mL/hr every hour	200 mL/hr
Week 2 (16 mg/kg) infusion[b]	500 mL	50 mL/hr	50 mL/hr every hour	200 mL/hr
Subsequent (Week 3 onward, 16 mg/kg) infusions[c]	500 mL	100 mL/hr	50 mL/hr every hour	200 mL/hr

[a] Consider incremental escalation of the infusion rate only in the absence of infusion reactions.

[b] Use a dilution volume of 500 mL for the 16 mg/kg dose only if there were no infusion reactions the previous week. Otherwise, continue to use a dilution volume of 1,000 mL.

[c] Use a modified initial rate (100 mL/hr) for subsequent infusions (i.e., Week 3 onward) only if there were no infusion reactions during the previous infusion. Otherwise, continue to use instructions indicated in the chart for the Week 2 infusion rate.

See Dose Adjustments and Antidote.

ACTIONS

A CD38-directed cytolytic antibody. CD38 is a transmembrane glycoprotein expressed on the surface of hematopoietic cells, including multiple myeloma and other cell types and tissues, and has multiple functions. Daratumumab is an IgG1_k human monoclonal antibody that binds to CD38 and inhibits the growth of CD38-expressing tumor cells by inducing apoptosis. When daratumumab is administered as monotherapy, steady state is achieved approximately 5 months into the every-4-week dosing period (by the 21st infusion). Half-life is 9 to 27 days when administered as monotherapy and is similar when administered as combination therapy.

INDICATIONS AND USES

For treatment of adult patients with multiple myeloma:

In combination with lenalidomide and dexamethasone in newly diagnosed patients who are ineligible for autologous stem cell transplant and in patients with relapsed or refractory multiple myeloma who have received at least one prior therapy. ■ In combination with bortezomib, melphalan, and prednisone in newly diagnosed patients who are ineligible for autologous stem cell transplant. ■ In combination with bortezomib, thalidomide, and dexamethasone in newly diagnosed patients who are eligible for autologous stem cell transplant. ■ In combination with bortezomib and dexamethasone, in patients who have received at least one prior therapy. ■ In combination with pomalidomide and dexamethasone in patients who have received at least two prior therapies, including lenalidomide and a proteasome inhibitor. ■ As monotherapy in patients who have received at least 3 prior lines of therapy, including a proteasome inhibitor (PI) and an immunomodulatory agent, or for patients who are double-refractory to a PI and an immunomodulatory agent.

CONTRAINDICATIONS

History of severe hypersensitivity (e.g., anaphylactic reactions) to daratumumab or any of the components of the formulation.

PRECAUTIONS

For IV infusion only. ■ Administered under the direction of a physician knowledgeable in its use in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ Can cause severe infusion reactions, including anaphylactic reactions. Approximately half of all patients experienced a reaction in clinical trials. Most reactions occur during the first infusion and are Grade 1 to 2. Reactions can also occur with subsequent infusions. Most reactions occur during the infusion or within 4 hours of administration. Premedication required; see Usual Dose. ■ To reduce the risk of delayed infusion reactions, administer postinfusion medications; see Usual Dose. ■ Interferes with serologic testing (compatibility testing, including cross-matching and antibody screening) for up to 6 months after the last infusion; see Drug/Lab Interactions. ■ Daratumumab may increase neutropenia and thrombocytopenia induced by background therapy; see Monitor and Antidote. ■ Daratumumab is a human IgG kappa monoclonal antibody that can be detected on assays used for monitoring endogenous M protein. Interference with these assays can affect the determination of complete response and of disease progression in some patients with IgG kappa myeloma protein; see Drug/Lab Interactions. ■ Has not been studied in patients with severe hepatic impairment. ■ A therapeutic protein; has the potential for immunogenicity.

Monitor:

Type and screen patients' blood before starting daratumumab. ■ Obtain baseline CBC with differential and platelet count and monitor as indicated during therapy and/or as recommended by manufacturer's prescribing information for background therapies; see Dose Adjustments. ■ Monitor vital signs. ■ Monitor for S/S of infusion reactions (e.g., bronchospasm, chest discomfort, cough, chills, dyspnea, fever, hypertension, hypotension, hypoxia, laryngeal edema, nasal congestion, nausea, pruritus, pulmonary edema, rhinitis, throat irritation, vomiting, wheezing). Median time to onset of an infusion reaction was 1.5 hours (range: 0 to 72.8 hours). Immediately interrupt the infusion for infusion reactions of any grade/severity; see Dose Adjustments and

Antidote. ■ Monitor patients with neutropenia for S/S of infection.

Patient Education:

Review manufacturer's medication guide. ■ Effective contraception required for women of reproductive potential during treatment with and for 3 months after the last dose of daratumumab. ■ Immediately report any S/S of infusion-related reactions (e.g., chills; cough; difficulty breathing; headache; itchy, runny, blocked nose; nausea; shortness of breath; throat irritation). ■ Report fever or S/S of infection. ■ Report any signs of bruising or bleeding. ■ Some side effects may require corticosteroid treatment and interruption or discontinuation of daratumumab. ■ Daratumumab can affect the results of some tests, including testing for complete response, and additional testing may be indicated to evaluate response to therapy. ■ Inform all health care providers, including blood transfusion centers, of daratumumab use in the event of a planned blood transfusion. ■ Inform health care provider of history of hepatitis B infection; reactivation can occur.

Maternal/Child:

Has the potential to be transmitted from the mother to the developing fetus. Based on its mechanism of action, daratumumab may cause fetal myeloid or lymphoid-cell depletion and decreased bone density. Effective contraception required; see Patient Education. ■ Administration of live vaccines to neonates and infants exposed to daratumumab in utero should be deferred until a hematology evaluation is completed. ■ Safety for use during breast-feeding is unknown. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety or efficacy were reported between elderly patients and younger adults.

DRUG/LAB INTERACTIONS

No drug interaction studies have been performed. ■ Coadministration of lenalidomide, pomalidomide, or bortezomib did not affect the pharmacokinetics of daratumumab. ■ Coadministration of daratumumab with bortezomib or pomalidomide did not affect the pharmacokinetics of bortezomib or pomalidomide. ■ Interferes with serologic testing. Daratumumab binds to CD38 on the RBCs and results in a positive indirect antiglobulin test (Coombs test). This effect may last for up to 6 months after the final daratumumab infusion. Daratumumab bound to RBCs masks detection of antibodies to minor antigens in the patient's serum. A patient's ABO and Rh blood type are not affected. Notify blood transfusion centers of this interference. ■ Daratumumab may be detected on assays used for monitoring disease monoclonal immunoglobulins (M protein). This can lead to a false-positive result for patients with IgG kappa myeloma protein and affect the initial assessment of complete responses. In patients with persistent very good partial responses in which daratumumab interference is suspected, consider using an FDA-approved daratumumab-specific IFE assay to distinguish daratumumab from any remaining endogenous M protein in the patient's serum to facilitate determination of a complete response. ■ Administration of live vaccines to neonates and infants exposed to daratumumab in utero should be deferred until a hematology evaluation is completed.

SIDE EFFECTS

The most frequently reported side effects included arthralgia, asthenia, back pain, bronchitis, chills, constipation, cough, decreased appetite, diarrhea, dizziness, dyspnea, fatigue, fever, infusion reactions, insomnia, muscle spasms, nausea, neutropenia, peripheral edema, peripheral sensory neuropathy, pneumonia, thrombocytopenia, upper respiratory tract infections, and vomiting. Less frequently reported side effects include anxiety, bone pain, extremity pain, headache, herpes zoster reactivation, hypertension, hyperglycemia, hypocalcemia, hypokalemia, musculoskeletal chest pain, nasal congestion, nasopharyngitis, noncardiac chest pain, paresthesia, tremor, and urinary tract infections. The most frequent serious side effects were atrial fibrillation, bronchitis, dehydration, diarrhea, fever, general physical health deterioration, influenza, infusion reactions, pneumonia, pulmonary edema, and upper respiratory tract infections. Treatment-emergent hematology laboratory abnormalities, including anemia, leukopenia, lymphopenia, neutropenia, and thrombocytopenia, were reported. Grade 3 and 4 infections were reported in patients receiving combination therapy. Hepatitis B virus (HBV) reactivation (including fatal cases) has been reported in fewer than 1% of patients.

Post-Marketing:

Anaphylaxis.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Interrupt daratumumab infusion for infusion reactions of any severity. For patients with Grade 1, 2, or 3 reactions, reduce the infusion rate when restarting the infusion; see Dose Adjustments and Rate of Administration. Permanently discontinue daratumumab for recurrence of a third Grade 3 or a Grade 4 (life-threatening) hypersensitivity/infusion reaction occurs. Treat a hypersensitivity/infusion reaction with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors (e.g., dopamine), corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Consider supportive care with growth factors (e.g., filgrastim) in patients who develop neutropenia and with transfusions in patients who develop thrombocytopenia.

DARBEPOETIN ALFA BBW

(**DAR**-beh-**poh**-eh-tin **AL**-fah)
Aranesp
Erythropoiesis-stimulating agent (ESA)
pH 6 to 6.4

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Monitor.

Adult and pediatric patients:

Rate of hemoglobin increase is dose dependent and varies among patients. Availability of iron stores, baseline hemoglobin, and concurrent medical problems affect the rate and extent of response. In controlled clinical trials, patients experienced greater risks for death, serious adverse cardiovascular reactions, and stroke when administered erythropoiesis-stimulating agents (ESAs) to target a hemoglobin level of greater than 11 Gm/dL. Use the lowest dose for each patient that will gradually increase the hemoglobin concentration to avoid the need for RBC transfusion. If a patient fails to respond or maintain a response, other etiologies should be considered and evaluated. See Monitor, Precautions, and Maternal/Child.

Anemia due to chemotherapy in cancer patients:

Start only if Hgb is less than 10 g/dl and anticipated duration of myelosuppressive chemo is at least 2 additional months. 2.25 mcg/kg once weekly or 500 mcg once every 3 weeks until chemo is completed.

Anemia associated with chronic kidney disease (CKD) for patients on dialysis:

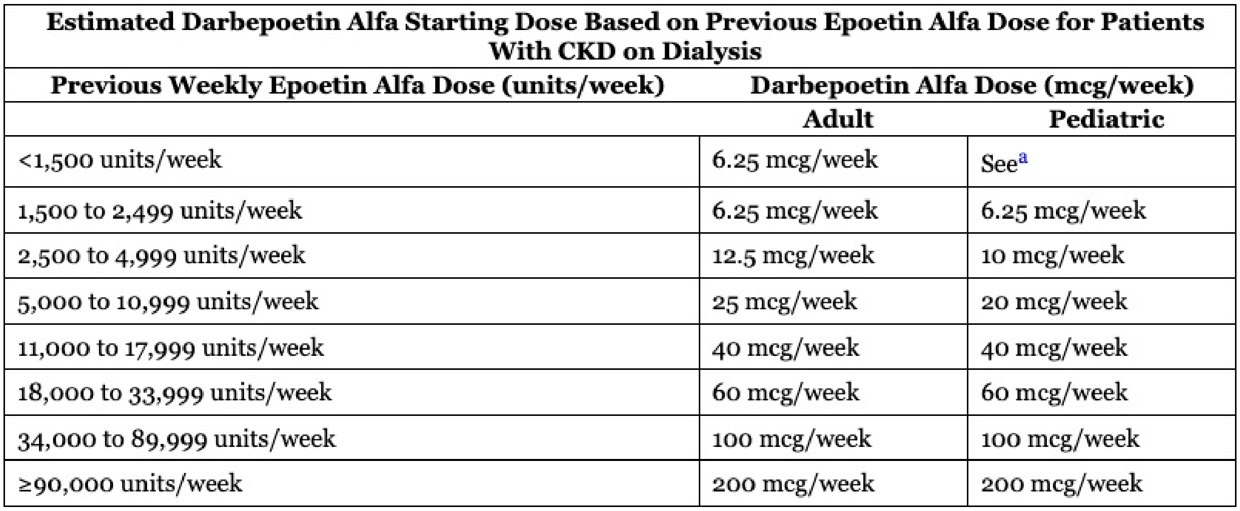
Initiate darbepoetin when the hemoglobin level is less than 10 Gm/dL: ***Starting dose:*** 0.45 mcg/kg of body weight once per week or 0.75 mcg/kg once every 2 weeks as appropriate. May be given by IV or SC injection. The IV route is recommended for patients on hemodialysis; see Precautions. See Dose Adjustments and Maternal/Child.

Anemia associated with chronic kidney disease (CKD) for patients NOT on dialysis:

Consider initiating darbepoetin only when the hemoglobin level is less than 10 Gm/dL and the following two considerations apply: (1) the rate of hemoglobin decline indicates the likelihood of requiring a RBC transfusion, and (2) reducing the risk of alloimmunization and/or other RBC transfusion-related risks is a goal. ***Starting dose:*** 0.45 mcg/kg of body weight IV or SC given once every 4 weeks as appropriate.

Conversion from epoetin alfa to darbepoetin alfa in patients with CKD on dialysis:

Estimate starting weekly dose of darbepoetin for adult and pediatric patients based on the weekly dose of epoetin alfa at the time of substitution as shown in the following chart. Administer darbepoetin once per week in patients who were receiving epoetin alfa 2 to 3 times a week and once every 2 weeks in patients who were receiving epoetin alfa once per week. The route of administration (IV or SC) should remain the same.



Estimated Darbepoetin Alfa Starting Dose Based on Previous Epoetin Alfa Dose for Patients With CKD on Dialysis

Previous Weekly Epoetin Alfa Dose (units/week)	Darbepoetin Alfa Dose (mcg/week)	
	Adult	Pediatric
<1,500 units/week	6.25 mcg/week	See[a]
1,500 to 2,499 units/week	6.25 mcg/week	6.25 mcg/week
2,500 to 4,999 units/week	12.5 mcg/week	10 mcg/week
5,000 to 10,999 units/week	25 mcg/week	20 mcg/week
11,000 to 17,999 units/week	40 mcg/week	40 mcg/week
18,000 to 33,999 units/week	60 mcg/week	60 mcg/week
34,000 to 89,999 units/week	100 mcg/week	100 mcg/week
≥90,000 units/week	200 mcg/week	200 mcg/week

[a] Data insufficient to determine a darbepoetin alfa conversion dose in pediatric patients receiving a weekly epoetin alfa dose of less than 1,500 units/week.

Conversion from epoetin alfa to darbepoetin alfa in patients with CKD NOT on dialysis:

The dose conversion shown in the previous chart (for patients with CKD on dialysis) does not accurately estimate the once-monthly dose of darbepoetin.

Anemia associated with chemotherapy in cancer patients:

ESAs shortened overall survival and/or increased the risk of tumor progression or recurrence in clinical studies of patients with certain types of cancer; see Precautions. Initiate darbepoetin in patients undergoing cancer chemotherapy only if the hemoglobin is less than 10 Gm/dL and there is a minimum of 2 additional months of planned chemotherapy. Use the lowest dose necessary to avoid RBC transfusions. ***Starting dose:*** 2.25 mcg/kg of body weight SC every week until completion of chemotherapy course. An alternative schedule is 500 mcg SC every 3 weeks until completion of chemotherapy course.

PEDIATRIC DOSE

Pediatric patients with CKD (under 18 years of age):

Initiate darbepoetin when the hemoglobin level is less than 10 Gm/dL. ***Starting dose:*** 0.45 mcg/kg of body weight once per week as an IV or SC injection. Patients not receiving dialysis may also be initiated at a dose of 0.75 mcg/kg once every 2 weeks. If the hemoglobin level approaches or exceeds 12 Gm/dL, reduce or interrupt the dose of darbepoetin.

DOSE ADJUSTMENTS

All patients with CKD:

When adjusting therapy, consider hemoglobin rate of rise, hemoglobin rate of decline, ESA responsiveness, and hemoglobin variability. A single hemoglobin excursion may not require a dose adjustment. Dose should be started slowly and adjusted for each patient to achieve and maintain the lowest hemoglobin level sufficient to avoid the need for RBC transfusion. Allow sufficient time before adjusting a dose; increased hemoglobin levels may not be observed for 2 to 6 weeks. ■ Do not increase the dose more frequently than once every 4 weeks. Decreases in dose can occur more frequently. Avoid frequent dose adjustments. ■ If the hemoglobin rises rapidly (e.g., more than 1 Gm/dL in any 2-week period), reduce the dose by 25% or more as needed to reduce rapid responses. ■ For patients who do not respond adequately (e.g., the hemoglobin has not increased by more than 1 Gm/dL) after 4 weeks of therapy, increase the dose by 25%. ■ For patients who do not respond adequately over a 12-week escalation period, increasing the dose further is unlikely to improve response and may increase risks. Discontinue darbepoetin if responsiveness does not improve.

Adult patients with CKD on dialysis:

If the hemoglobin level approaches or exceeds 11 Gm/dL, reduce or interrupt the dose of darbepoetin.

Adult patients with CKD NOT on dialysis:

If the hemoglobin level exceeds 10 Gm/dL, reduce or interrupt the dose of darbepoetin and use the lowest dose sufficient to reduce the need for RBC transfusions.

Pediatric patients with CKD:

See Pediatric Dose.

Anemia associated with chemotherapy in cancer patients:

Dose Adjustment in Patients Undergoing Cancer Chemotherapy		
Dose Adjustment	**Weekly Schedule**	**Every-3-Week Schedule**
If hemoglobin increases more than 1 Gm/dL in any 2-week period **or** If hemoglobin reaches a level needed to avoid RBC transfusion	Reduce dose by 40%	Reduce dose by 40%
If hemoglobin exceeds a level needed to avoid RBC transfusion	Withhold dose until hemoglobin approaches level at which RBC transfusions may be required Reinitiate at a dose 40% below the previous dose	Withhold dose until hemoglobin approaches level at which RBC transfusions may be required Reinitiate at a dose 40% below the previous dose
If hemoglobin increases by less than 1 Gm/dL **and** remains below 10 Gm/dL after 6 weeks of therapy	Increase dose to 4.5 mcg/kg/week	No dose adjustment
If there is no response as measured by hemoglobin levels **or** if RBC transfusions are still required after 8 weeks of therapy Following completion of a chemotherapy course	Discontinue darbepoetin	Discontinue darbepoetin

DILUTION

Available in numerous concentrations. Supplied in vials or prefilled syringes with needle guards (needle cover contains a derivative of latex). Must be given undiluted as an IV injection. Do not administer in conjunction with other drug solutions. ***Do not shake*** and keep covered to protect from room light until administration. Vigorous shaking or exposure to light will render solution biologically inactive. Single-dose vial contains no preservatives. Use only 1 dose per vial, then discard.

Filters:

Not required; however, it was filtered during manufacturing with 0.2-micron filters. No significant loss of potency expected with use of non–protein binding filters of a similar size or larger.

Storage:

Store in carton at 2° to 8° C (36° to 46° F). Do not freeze or shake. Protect from light.

COMPATIBILITY

Manufacturer states, “Do not administer in conjunction with other drug solutions.”

RATE OF ADMINISTRATION

A single dose over at least 1 minute.

ACTIONS

An erythropoiesis-stimulating protein produced by recombinant DNA technology. Closely related to human erythropoietin. Production of endogenous erythropoietin is impaired in patients with chronic renal failure, and erythropoietin deficiency is the primary cause of their anemia. Darbepoetin has the same biologic effects as erythropoietin produced naturally by the kidneys. Stimulates bone marrow to produce RBCs, increasing the reticulocyte count within 10 days and the red cell count, hemoglobin, and hematocrit within 2 to 6 weeks. Normal iron stores are necessary because it steps up RBC production to a rate above what the body usually makes. New cells need iron, which is quickly depleted. Distribution is confined to the vascular space. Half-life is approximately 21 hours. Continued therapy will maintain improved RBC levels and decrease the need for transfusions.

INDICATIONS AND USES

Treatment of anemia associated with chronic kidney disease, including patients receiving dialysis and patients not receiving dialysis. ■ As a SC injection to treat chemotherapy-induced anemia in adult cancer patients who have nonmyeloid malignancies in which anemia is a result of the effect of concomitant myelosuppressive chemotherapy and who, upon initiation of therapy, have a minimum of 2 additional months of planned chemotherapy.

Limitations of use:

Not indicated for use in patients with cancer receiving hormonal agents, therapeutic biologic products, or radiotherapy unless receiving concomitant myelosuppressive chemotherapy. ■ Not indicated for patients receiving myelosuppressive chemotherapy when the anticipated outcome is cure; see Precautions. ■ Not indicated in patients with cancer receiving myelosuppressive chemotherapy in whom the anemia can be managed by transfusion. ■ Has not been shown to improve quality of life, fatigue, or patient well-being; see Precautions. ■ Not indicated as a substitute for a RBC transfusion in patients who require immediate correction of anemia.

CONTRAINDICATIONS

Known hypersensitivity to darbepoetin. ■ Uncontrolled hypertension. ■ Pure red cell aplasia (PRCA) that begins after treatment with darbepoetin or other erythropoietin agents.

PRECAUTIONS

May be given IV or SC to patients not receiving dialysis. ■ Erythropoiesis-stimulating agents (ESAs) increase the risk of death, MI, stroke, congestive heart failure, venous thromboembolism, thrombosis of hemodialysis vascular access, other thromboembolic events, and tumor progression or recurrence. Patients experienced greater risks of these adverse events when ESAs were administered to target a hemoglobin of greater than 11 Gm/dL. No trial has identified a hemoglobin target level, a darbepoetin dose, or a dosing strategy that does not increase these risks. Use the lowest darbepoetin dose sufficient to reduce the need for RBC transfusions. ■ Use with caution in patients with coexistent cardiovascular disease and stroke. Patients with CKD and an insufficient hemoglobin response to ESA therapy may be at even greater risk for cardiovascular reactions and mortality than other patients. ■ In clinical trials, ESAs increased the risk of death in patients undergoing CABG surgery and the risk of deep venous thrombosis in patients undergoing orthopedic procedures. ■ Increases in hemoglobin of greater than 1 Gm/dL during any 2-week period have been associated with an increased incidence of cardiac arrest, neurologic events (e.g., seizures, stroke), exacerbations of hypertension, congestive heart failure (CHF), vascular thrombosis/ischemia/infarction, acute MI, deep vein thrombosis (DVT), pulmonary embolus, hemodialysis graft occlusion, and fluid overload/edema. See Dose Adjustments. ■ Administration of ESAs to cancer patients shortened the overall survival time and/or increased the risk of tumor progression or recurrence in clinical studies of some patients with breast, cervical, head and neck, lymphoid, and non–small-cell lung malignancies. To minimize these risks, as well as the risks of serious cardiovascular and thrombovascular events, use the lowest dose needed to avoid a red blood cell transfusion. Use only to treat anemia due to concomitant myelosuppressive chemotherapy, and discontinue after completion of a chemotherapy course. ■ BP may increase during therapy with darbepoetin. Hypertensive encephalopathy and seizures have been observed. ■ Patients with uncontrolled hypertension should not be treated with darbepoetin until BP has been adequately controlled. ■ In addition to low baseline hemoglobin and inadequate iron stores, delayed or diminished response may result from concurrent medical problems (e.g., infections, inflammatory or malignant processes, occult blood loss, underlying hematologic disease, folic acid or vitamin B_{12} deficiency, hemolysis, aluminum intoxication, osteofibrosis cystica, bone marrow fibrosis, pure red cell aplasia [PRCA], or anti-erythropoietin antibody–associated anemia). Correct or exclude other causes of anemia before initiating therapy. Not intended for use in anemia caused by iron or folate deficiencies, hemolysis, or GI bleeding or for use in treating symptoms of anemia, including dizziness, fatigue, low energy, poor quality of life, or shortness of breath. ■ Safety and efficacy have not been established in patients with underlying hematologic diseases (e.g., hemolytic anemia, sickle cell anemia, thalassemia, porphyria). ■ Therapy results in an increase in RBCs and a decrease in plasma volume, which could reduce dialysis efficiency; adjustment of dialysis prescription may be necessary. ■ Darbepoetin increases the risk of seizures in patients with CKD. Use with caution in patients with epilepsy. ■ As with all proteins, there is a potential for immunogenicity. The incidence of antibody development in patients receiving darbepoetin has not been determined. Use caution; hypersensitivity reactions and/or anaphylaxis can occur. ■ Pure red cell aplasia (PRCA) and severe anemia, with or without other cytopenias, in association with neutralizing antibodies to erythropoietin have been observed. Most often reported in CKD patients receiving epoetin alfa by SC injection. Evaluate any patient who develops a sudden loss of response to darbepoetin alfa accompanied by severe anemia and low reticulocyte count. Physicians may contact the manufacturer (Amgen) for help with evaluation of these patients. ■ Blistering and skin exfoliation reactions, including erythema multiforme and Stevens-Johnson syndrome (SJS)/toxic epidermal necrolysis (TEN) have been reported. Discontinue therapy immediately if a severe cutaneous reaction is suspected. ■ Darbepoetin is a growth factor that stimulates RBC production. Erythropoietin receptors are also found on the surfaces of normal, nonhematopoietic tissue and some malignant cell lines. The possibility that darbepoetin can act as a growth factor for any tumor type cannot be ruled out.

Monitor:

Normal iron stores required to support epoetin-stimulated erythropoiesis. Transferrin saturation should be at least 20% and ferritin at least 100 ng/mL (100 mcg/L). Monitor before and during therapy. ■ Monitor hemoglobin weekly in patients who are initiating therapy. Continue until stable and the maintenance dose has been established, then monitor at regular intervals (at least monthly). ■ Monitor hemoglobin weekly for at least 4 weeks following adjustment of therapy. Once stabilized, continue to monitor at regular intervals (at least monthly). ■ Monitor BP routinely. Initiation or intensification of antihypertensive therapy and dietary restrictions may be necessary. If BP is difficult to control by pharmacologic or dietary measures, the dose of darbepoetin should be reduced or withheld. ■ Monitor for the presence of premonitory neurologic symptoms during the first several months after initiation of therapy. Seizures have been reported; see Precautions. ■ Monitor for S/S of hypersensitivity reactions (e.g., anaphylaxis, angioedema, bronchospasm, rash, urticaria). ■ Supplemental iron is usually required to increase and maintain iron stores. Administration of parenteral iron may be necessary in some patients.

Patient Education:

Risk of seizures, especially for first several months of therapy. Do not drive or operate heavy equipment. Promptly report new-onset neurologic symptoms or change in seizure frequency. ■ Stress the importance of compliance with diet, iron and vitamin (e.g., folic acid, B_{12}) supplementation, BP control, and dialysis regimen. ■ Close monitoring of BP and hemoglobin is imperative. ■ Promptly report S/S of a hypersensitivity reaction, pain or swelling in the legs, shortness of breath (SOB), increase in BP, dizziness, or loss of consciousness. ■ Menses may resume; possibility of pregnancy. Contraception may be indicated. ■ Additional instruction (e.g., equipment, techniques) will be required in patients who will self-administer (manufacturer supplies brochure). ■ Increased risk of mortality, serious cardiovascular events, thromboembolic events, and tumor progression or recurrence. ■ Read medication guide and instructions for use carefully. All patients should discuss the risks of using an ESA with a health care professional.

Maternal/Child:

Use caution. Consider the benefits and risks of darbepoetin for the mother and possible risks to the fetus. ■ Use caution in nursing mothers. ■ Safety and effectiveness of darbepoetin alfa in pediatric patients with CKD receiving dialysis or not receiving dialysis have been established in the age-groups 1 month to 16 years. ■ Safety and effectiveness were similar between adult and pediatric patients with CKD when darbepoetin was used for the initial treatment of anemia or when patients were transitioned from another erythropoietin to darbepoetin. ■ Safety and effectiveness for use in pediatric cancer patients not established. ■ Half-life and plasma concentrations in pediatric patients 3 years of age and older are similar to those seen in adults. See package insert.

Elderly:

No differences in safety or efficacy were observed between older and younger patients.

DRUG/LAB INTERACTIONS

Specific information not available.

SIDE EFFECTS

Adult chronic kidney disease patients:

Commonly reported adverse reactions include cough, dyspnea, hypertension, peripheral edema, and procedural hypotension. ***Serious*** adverse reactions include hypertension, increased mortality, MI, PRCA, seizures, serious hypersensitivity reactions, stroke, and thromboembolism. Other reported adverse reactions include angina, arteriovenous graft thrombosis, fluid overload, rash, and vascular access complications.

Pediatric chronic kidney disease patients:

Commonly reported adverse reactions include convulsions, hypertension, injection site pain, and rash. ***Serious*** adverse reactions include convulsions and hypertension.

Cancer patients receiving chemotherapy:

Commonly reported adverse reactions include abdominal pain, edema, and thrombovascular events. ***Serious*** adverse reactions include hypertension, increased mortality, increased risk of tumor progression or recurrence, MI, PRCA, seizures, serious hypersensitivity reactions, stroke, and thromboembolism.

Post-Marketing:

PRCA and severe anemia, with or without other cytopenias, in association with neutralizing antibodies have been reported; see Precautions. Seizures, severe cutaneous reactions, and serious hypersensitivity reactions have also been reported.

ANTIDOTE

Notify physician of all side effects; most will be treated symptomatically. Excessive hypertension may require discontinuation of darbepoetin until BP is controlled or may respond to a reduction in dose of darbepoetin or to an increase in antihypertensive therapy. Reduce dose of darbepoetin in patients with an increase in hemoglobin of more than 1 Gm/dL in 2 weeks. May need to withhold darbepoetin until hemoglobin falls to desired goal. Consider phlebotomy in the event of overdose or polycythemia. If overdose or polycythemia does occur, monitor closely for cardiovascular events and hematologic abnormalities. When resuming therapy, monitor closely for evidence of rapid increases in hemoglobin concentration (greater than 1 Gm/dL within 14 days) and reduce dose as indicated. Adjustments in dialysis prescription may be required during dialysis to prevent clotting. Permanently discontinue therapy in patients with antibody-mediated anemia (PRCA). Patients should not be switched to other erythropoietic proteins, because antibodies may cross-react. Treat minor hypersensitivity reactions symptomatically. Discontinue drug and treat anaphylaxis as indicated; resuscitate as necessary.

DAUNORUBICIN AND CYTARABINE LIPOSOME FOR INJECTION BBW

(**DAW**-noe-**ROO**-bi-sin and sye-**TAR**-a-been **LYE**-poe-sohm)
Vyxeos
Antineoplastic
(Anthracycline)

USUAL DOSE

Do not interchange with other products containing daunorubicin and/or cytarabine. Vyxeos has different dose recommendations than daunorubicin hydrochloride, cytarabine, daunorubicin citrate liposome injection, and cytarabine liposome injection. Verify drug name and dose before preparation and administration to avoid dosing errors.

Pretreatment Requirements:

Verify pregnancy status. Before initiating each cycle of Vyxeos, calculate the prior cumulative anthracycline exposure for the patient; see Precautions. Before initiating induction and each consolidation cycle, obtain an ECG and assess cardiac function by multigated radionuclide angiography (MUGA) scan or echocardiography (ECHO). Obtain CBC and liver and renal function studies before each consolidation cycle and as indicated; see Monitor.

Premedication:

Administer prophylactic antiemetics before each treatment.

A full Vyxeos course consists of 1 to 2 cycles of induction and up to 2 cycles of consolidation. Do not start consolidation cycles until the absolute neutrophil count recovers to greater than 500/mm^3 and the platelet count recovers to greater than 50,000/mm^3 in the absence of unacceptable toxicity.

First cycle of induction:

Daunorubicin 44 mg/M^2 and cytarabine 100 mg/M^2 as an IV infusion over 90 minutes on Days 1, 3, and 5.

Second induction cycle:

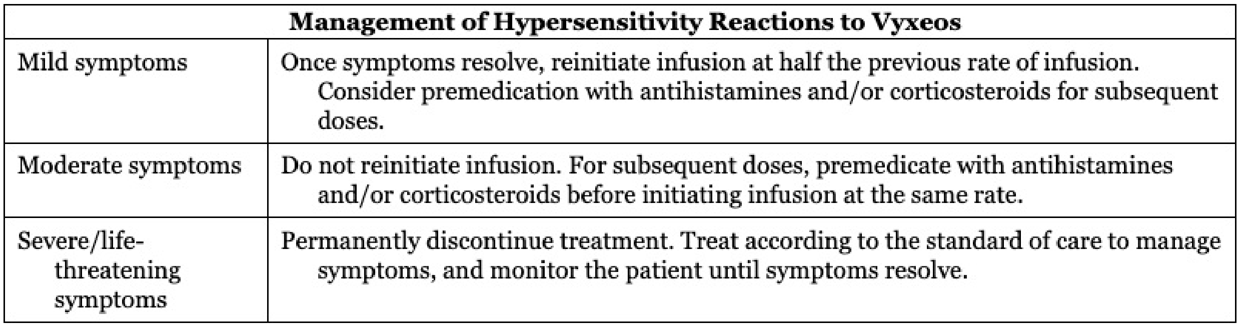
If remission is not achieved with the first induction cycle, a second induction cycle may be administered 2 to 5 weeks after the first cycle if no unacceptable toxicity occurred. Administer daunorubicin 44 mg/M^2 and cytarabine 100 mg/M^2 as an IV infusion over 90 minutes on Days 1 and 3.

Consolidation:

Administer the first consolidation cycle 5 to 8 weeks after the start of the last induction. Dose for consolidation is daunorubicin 29 mg/M^2 and cytarabine 65 mg/M^2 as an IV infusion over 90 minutes on Days 1 and 3. Administer the second consolidation cycle 5 to 8 weeks after the first in patients who do not show disease progression or unacceptable toxicity.

DOSE ADJUSTMENTS

Dose adjustment is not required for patients with mild or moderate renal impairment or in patients with hepatic impairment with a bilirubin level 3 mg/dL or less. ■ No dose adjustment required based on age, body mass index, body weight, race, sex, and white blood cell count after adjusting dose by body surface area. ■ Discontinue Vyxeos in patients who exhibit impaired cardiac function unless the benefit of continuing treatment outweighs the risk. ■ If a planned dose is missed, administer the dose as soon as possible and adjust the dosing schedule accordingly to maintain the treatment interval. ■ For hypersensitivity reactions of any grade/severity, interrupt the infusion immediately and manage symptoms. Reduce the rate of infusion or discontinue treatment as outlined in the following chart.



Management of Hypersensitivity Reactions to Vyxeos	
Mild symptoms	Once symptoms resolve, reinitiate infusion at half the previous rate of infusion. Consider premedication with antihistamines and/or corticosteroids for subsequent doses.
Moderate symptoms	Do not reinitiate infusion. For subsequent doses, premedicate with antihistamines and/or corticosteroids before initiating infusion at the same rate.
Severe/life-threatening symptoms	Permanently discontinue treatment. Treat according to the standard of care to manage symptoms, and monitor the patient until symptoms resolve.

DILUTION

Specific techniques required; see Precautions. Available as a lyophilized cake in a single-dose vial. Calculate the dose based on daunorubicin and individual patient's BSA. Calculate the number of vials required based on the daunorubicin dose. Remove required vials from refrigeration and equilibrate to RT for 30 minutes. Reconstitute each vial with 19 mL of SWFI. Immediately start a 5-minute timer and ***carefully swirl the contents of the vial for 5 minutes*** while gently inverting the vial every 30 seconds. Do not heat, vortex, or shake vigorously. After reconstitution, allow to rest for 15 minutes. Should be an opaque, purple, homogeneous dispersion. Each mL contains 2.2 mg of daunorubicin and 5 mg of cytarabine. Calculate the volume of reconstituted solution required using the following formula:

$$\text{Volume required (mL)} = \text{Dose of daunorubicin (mg/M}^2\text{)} \times \text{Patient's BSA (M}^2\text{)} \div 2.2 \text{ (mg/mL)}$$

Gently invert each vial 5 times before withdrawing the reconstituted product for further dilution. Withdraw the calculated volume and transfer to a 500-mL infusion bag of NS or D5W. Gently invert bag to mix the solution.

Filters:

Manufacturer states, “An in-line membrane filter may be used for the IV infusion provided the minimum pore diameter of the filter is greater than or equal to 15 micrometers.”

Storage:

Refrigerate unreconstituted vials at 2° to 8° C (36° to 46° F) in original carton to protect from light. Should be stored in an upright position. Reconstituted product in the vial and fully diluted solutions may be refrigerated for up to 4 hours if not used immediately. Discard unused product.

COMPATIBILITY

Manufacturer states, “Do not mix Vyxeos with or administer as an infusion with other drugs.”

RATE OF ADMINISTRATION

Use an infusion pump to administer by constant IV infusion over 90 minutes through a central venous catheter or a peripherally inserted central catheter. Flush the line before and after administration with NS or D5W.

ACTIONS

Vyxeos is a combination of daunorubicin and cytarabine in a 1:5 molar ratio encapsulated in liposomes. Daunorubicin is an anthracycline topoisomerase inhibitor, and cytarabine is a nucleoside metabolic inhibitor. The combination has been shown to have synergistic effects at killing leukemia cells in vitro and in murine models. Daunorubicin has antimitotic and cytotoxic activity. Cytarabine is a cell-cycle phase–specific antineoplastic agent, affecting cells only during the S-phase of cell division. Based on animal data, the liposomes enter and persist in the bone marrow and are taken up by leukemia cells to a greater extent than by normal bone marrow cells. After cellular internalization, liposomes undergo degradation, releasing cytarabine and daunorubicin within the intracellular environment. Half-life is 31.5 hours for daunorubicin and 40.4 hours for cytarabine. Metabolized to active and inactive metabolites with some excretion in urine.

INDICATIONS AND USES

Treatment of adults with newly diagnosed therapy-related acute myeloid leukemia (t-AML) or AML with myelodysplasia-related changes (AML-MRC).

CONTRAINDICATIONS

History of serious hypersensitivity reaction to cytarabine, daunorubicin, or any component of the formulation.

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ For IV use only. **Do not interchange with other products containing daunorubicin and/or cytarabine.** Vyxeos has different dose recommendations than daunorubicin hydrochloride, cytarabine, daunorubicin citrate liposome injection, and cytarabine liposome injection. Verify drug name and dose before preparation and administration to avoid dosing errors. ■ Daunorubicin has been associated with severe local tissue necrosis at the site of drug extravasation. ■ Serious or fatal hemorrhagic events associated with prolonged severe thrombocytopenia, including fatal CNS hemorrhages, have occurred. ■ Contains the anthracycline daunorubicin, which has a known risk of cardiotoxicity. Prior therapy with anthracyclines, pre-existing cardiac disease, previous radiotherapy to the mediastinum, or concomitant use of cardiotoxic drugs may increase the risk of daunorubicin-induced cardiac toxicity. Assessment of cardiac function is required before initiating therapy; see Usual Dose. Discontinue therapy in patients with impaired cardiac function unless the benefit of initiating or continuing treatment outweighs the risk. Vyxeos treatment is not recommended in patients with an LVEF that is less than normal. ■ Incidence of drug-induced CHF has been associated with cumulative doses of nonliposomal daunorubicin greater than 550 mg/M^2. Tolerable limit appears lower (400 mg/M^2) in patients who received radiation therapy to the mediastinum. Vyxeos treatment is not recommended in patients whose lifetime anthracycline exposure has reached the maximum cumulative limit. ■ Serious or fatal hypersensitivity reactions, including anaphylaxis, have been reported with daunorubicin and cytarabine. ■ Reconstituted Vyxeos contains copper gluconate (14% elemental copper). No clinical experience in patients with Wilson's disease or other copper-related metabolic disorders. The maximum theoretical total exposure of copper with the recommended dosing regimen is 106 mg/M^2. Use in patients with Wilson's disease only if the benefits outweigh the risks. ■ Has not been studied in patients with severe renal impairment (CrCl 15 to 29 mL/min), ERSD, or a bilirubin level greater than 3 mg/dL.

Monitor:

Pretreatment assessment required before initiating each cycle; see Usual Dose. ■ Monitor blood counts regularly until recovery, and administer platelet transfusion support as required. ■ Repeat MUGA scan or ECHO determinations of LVEF before consolidation and as clinically required. ■ Monitor for S/S of a hypersensitivity reaction (e.g., chest pain, chills, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritus, rash, urticaria). ■ In patients with Wilson's disease, risk of copper overload may require consultation with a hepatologist and nephrologist with expertise in managing acute copper toxicity. Monitor total serum copper, serum non-ceruloplasmin bound copper, 24-hour urine copper levels, and serial neuropsychological examinations in these patients. ■ Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; discontinue injection. Severe cellulitis and tissue necrosis will result from extravasation with conventional daunorubicin. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Patient Education:

Review all current medications with provider. ■ Promptly report IV site burning or stinging, S/S of a hypersensitivity reaction (e.g., light-headedness, rash, urticaria, tightness of the chest, wheezing), bleeding or bruising, dizziness, fever, infection, lack of coordination, loss of balance, numbness, severe headache, shortness of breath, sudden confusion, and swelling of extremities. ■ Effective contraception required during treatment and for 6 months after the last dose of Vyxeos in females of reproductive potential and in males with female partners of reproductive potential. Verify pregnancy status before initiating treatment. Notify provider of known or suspected pregnancy. ■ Periodic monitoring of blood counts imperative; transfusions may be required. ■ See Appendix D, p. 1311.

Maternal/Child:

Avoid pregnancy. Based on its mechanism of action, can cause fetal harm. Effective contraception required; see Patient Education. ■ Has potential for serious adverse reactions in breast-fed infants; breast-feeding is not recommended during treatment and for at least 2 weeks after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

No overall differences in safety observed except for bleeding events, which occurred more frequently in elderly patients compared with younger patients.

DRUG/LAB INTERACTIONS

Risk of cardiotoxicity may increase with concomitant use of Vyxeos and **cardiotoxic agents** such as other anthracyclines (e.g., doxorubicin, idarubicin) or alkylating agents (e.g., cyclophosphamide, ifosfamide, cisplatin, carmustine, busulfan, chlormethine, and mitomycin) and/or radiation encompassing the heart. Assess cardiac function more frequently. ■ Concomitant use with **hepatotoxic agents** (e.g., azathioprine, isoniazid, methotrexate, retinoids, sulfasalazine) may impair liver function and increase the toxicity of Vyxeos. Monitor hepatic function more frequently.

SIDE EFFECTS

Abdominal pain, arrhythmia, bacteremia, chills, constipation, cough, decreased appetite, diarrhea, dyspnea, edema, fatigue, febrile neutropenia, headache, hemorrhagic events, mucositis, musculoskeletal pain, nausea, pneumonia, rash, sleep disorders, and vomiting are most common. The most common serious adverse reactions are bacteremia, dyspnea, febrile neutropenia, hemorrhage, myocardial toxicity, pneumonia, and sepsis. Anxiety, catheter device/injection site reaction, chest pain, delirium, dizziness, fungal infection, hemorrhoids, hypertension, hypotension, hypoxia, nonconduction cardiotoxicity, petechiae, pleural effusion, pruritus, renal insufficiency, sepsis, transfusion reactions, and visual impairment have also been reported. Laboratory abnormalities include prolonged cytopenias (neutropenia and thrombocytopenia) and chemistry abnormalities (alanine aminotransferase, hyperbilirubinemia, hypoalbuminemia, hypokalemia, and hyponatremia). Other serious side effects may include cardiotoxicity, copper overload, hypersensitivity reactions, and tissue necrosis.

ANTIDOTE

Most side effects will be treated symptomatically. Keep physician informed. Close monitoring of cumulative dosage of daunorubicin, CBC, ECG, and LVEF may prevent most serious and potentially fatal side effects. Supportive therapy as indicated will help sustain the patient in toxicity. See Dose Adjustments for management of hypersensitivity reactions and treat as appropriate (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids). Discontinue in patients with S/S of acute copper toxicity Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. See daunorubicin hydrochloride monograph for extravasation. Resuscitate as necessary.

DAUNORUBICIN HYDROCHLORIDE BBW ■ DAUNORUBICIN CITRATE LIPOSOMAL INJECTION BBW

(daw-noh-**ROO**-bih-sin hy-droh-**KLOR**-eyed)
(daw-noh-**ROO**-bih-sin **SIH**-trate **LIP**-oh-sohm-ul)
Cerubidine ■ DaunoXome
Antineoplastic (anthracycline)
pH 4.5 to 6.5 ■ 4.9 to 6

USUAL DOSE

All Daunorubicins

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

Conventional Daunorubicin

Adult acute nonlymphocytic leukemia:

45 mg/M^2/day on Days 1, 2, and 3 in adults under age 60 (adults over age 60 may require reduction to 30 mg/M^2/day). Used in specific protocol combination therapy (e.g., cytarabine 100 mg/M^2/day for 7 days). Regimen repeated every 3 to 4 weeks. In these subsequent courses, repeat daunorubicin, 30 to 45 mg/M^2/day (depending on age) for only 2 days and cytarabine for only 5 days. To obtain a normal-appearing bone marrow may require up to 3 courses.

Adult acute lymphocytic leukemia:

45 mg/M^2/day on Days 1, 2, and 3. Used in combination therapy (e.g., vincristine, prednisone, and l-asparaginase). In all situations, when remission is complete, an individual maintenance program should be established.

DaunoXome (Liposomal Injection)

Advanced, HIV-associated Kaposi’s sarcoma:

40 mg/M^2 as an IV infusion. Repeat every 2 weeks. Continue treatment until there is evidence of disease progression (specifics outlined in package insert).

PEDIATRIC DOSE

Conventional Daunorubicin

See Maternal/Child.

Acute lymphocytic leukemia in pediatric patients 2 years of age and older:

25 mg/M^2/day on Day 1 each week, vincristine 1.5 mg/M^2 on Day 1 each week, and prednisone 40 mg/M^2 PO daily. Remission should be obtained in 4 weeks. If a partial remission is obtained after 4 weeks, 1 or 2 more weeks of treatment may produce a complete remission.

Acute lymphocytic leukemia in infants and children under 2 years of age or less than 0.5 M^2 body surface:

Calculate dose based on weight instead of body surface area: 1 mg/kg.

DaunoXome:

Safety for use in pediatric patients not established.

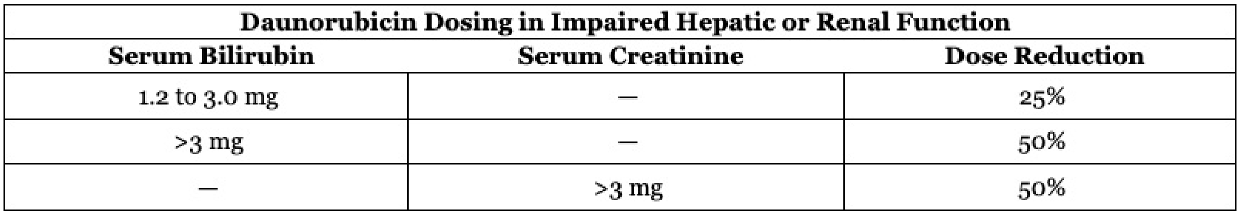
DOSE ADJUSTMENTS

All Daunorubicins:

See Precautions/Monitor.

Conventional Daunorubicin:

Profound bone marrow suppression is usually required to eradicate the leukemic cells and induce a complete remission. Evaluate bone marrow and peripheral blood to determine need for additional courses. ■ See Usual Dose for adults over 60 years of age. ■ Reduce dose in impaired hepatic or renal function according to the following chart.



Daunorubicin Dosing in Impaired Hepatic or Renal Function

Serum Bilirubin	Serum Creatinine	Dose Reduction
1.2 to 3.0 mg	—	25%
>3 mg	—	50%
—	>3 mg	50%

DaunoXome:

Reduce dose to 75% of normal (30 mg/M^2) if serum bilirubin is 1.2 to 3 mg/dL. Reduce dose to 50% of normal (20 mg/M^2) if serum bilirubin or creatinine is greater than 3 mg/dL. ■ Withhold dose if absolute granulocyte count is less than 750 cells/mm^3.

DILUTION

Specific techniques required;

see Precautions.

Conventional daunorubicin:

Each 20 mg must be diluted with 4 mL of SWFI (5 mg/mL). Agitate gently to dissolve completely. Further dilute each dose with 10 to 15 mL of NS. Must be given through Y-tube or three-way stopcock of a free-flowing infusion of D5W or NS. May be added to 100 mL NS and given as an infusion. Use extreme caution.

DaunoXome:

Dilute each single dose with an equal amount of D5W. Available as a 2 mg/mL preservative-free solution. Withdraw calculated volume (dose of DaunoXome) from vial; transfer to a sterile infusion bag that contains an equal volume of D5W. Desired concentration is 1 mg/mL. Do not use any other diluent. A translucent red liposomal dispersion; do not use if opaque. Do not use in-line filters for infusion. See Compatibility.

Filters:

DaunoXome:

Manufacturer states, “Do not use in-line filters for infusion.”

Storage:

Conventional daunorubicin:

Protect from sunlight. Diluted solution stable 24 hours at room temperature, 48 hours if refrigerated; then discard.

DaunoXome:

Refrigerate unopened vials; avoid freezing. Protect from light. Discard unused drug. Reconstituted solutions may be refrigerated for a maximum of 6 hours.

COMPATIBILITY

Conventional Daunorubicin

Manufacturer states, “Should not be administered mixed with other drugs or heparin.” Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

DaunoXome

Manufacturer states, “The only fluid that may be mixed with DaunoXome is D5W. Must not be mixed with saline, bacteriostatic agents such as benzyl alcohol, or any other solution.”

RATE OF ADMINISTRATION

Conventional Daunorubicin

IV injection:

A single dose of properly diluted medication over 3 to 5 minutes.

IV infusion:

A single dose evenly distributed over 30 to 45 minutes.

DaunoXome

A single dose as an infusion evenly distributed over 60 minutes. Do not use an in-line filter. Back pain, flushing, and chest tightness may occur. Usually subsides if infusion is stopped, and usually does not recur if infusion is restarted at a slower rate after symptoms subside.

ACTIONS

Conventional Daunorubicin:

A highly toxic antibiotic antineoplastic agent. Rapidly cleared from plasma, it inhibits synthesis of DNA. Cell-cycle specific for S phase; exact method of action is unknown; antimitotic, cytotoxic, and immunosuppressive. Widely distributed in tissues, with the highest concentrations occurring in the spleen, kidneys, liver, lungs, and heart. Does not cross blood-brain barrier. Metabolized in the liver and other tissues. Elimination half-life is 18 to 30 hours. Slowly excreted in bile and urine.

DaunoXome:

A liposomal preparation of daunorubicin formulated to maximize selectivity for solid tumors. In the circulation, the liposomal preparation protects the entrapped daunorubicin from chemical and enzymatic degradation, minimizes protein binding, and generally decreases uptake by normal (non–reticuloendothelial system) tissues. The mechanism of delivery is not known, but may be through the often altered and/or compromised vasculature of tumors. In animals, it has been shown to accumulate in tumors to a greater extent than conventional daunorubicin. Released over time within the cells of the solid tumor. Persists at high levels within tumor tissue for several days. It differs from conventional daunorubicin because it mostly confines itself to vascular fluid volume. Plasma clearance is slower and the AUC (area under the curve) is larger.

INDICATIONS AND USES

Conventional Daunorubicin:

Treatment of acute nonlymphocytic leukemia in adults (myelogenous, monocytic, erythroid). ■ Combination therapy for induction of remission in acute lymphocytic leukemia in adults and pediatric patients.

DaunoXome:

Currently approved only for first-line cytotoxic therapy for advanced HIV-associated Kaposi's sarcoma.

CONTRAINDICATIONS

Conventional Daunorubicin:

Hypersensitivity to daunorubicin or any of its components. ***Not absolute:*** Pre-existing bone marrow suppression, impaired cardiac function, pre-existing infection; see Precautions.

DaunoXome:

History of hypersensitivity reaction to previous treatment with DaunoXome or any of its components (includes conventional daunorubicin). Not recommended in patients with less than advanced HIV-related Kaposi's sarcoma.

PRECAUTIONS

All Daunorubicins:

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of the physician specialist with facilities for monitoring the patient and responding to any medical emergency. ■ For IV use only; do not give IM or SC. ■ Severe myelosuppression may occur and may lead to infection or hemorrhage. ■ Use extreme caution in pre-existing drug-induced bone marrow suppression, existing heart disease, previous treatment with other anthracyclines (e.g., doxorubicin), or radiation therapy encompassing the heart. ■ Incidence of myocardial toxicity increases after a total cumulative dose that exceeds 400 to 550 mg/M^2 in adults, 300 mg/M^2 in pediatric patients over 2 years of age, or 10 mg/kg in pediatric patients under 2 years of age. Potentially fatal congestive heart failure may occur either during therapy or months to years after therapy is complete. ■ Urine may be reddish color (from dye, not hematuria).

Monitor:

All Daunorubicins:

Monitor CBC including differential and platelet count before each dose. ■ Monitoring of liver function, kidney function, ECG, chest x-ray, echocardiography, and systolic ejection fraction indicated before and during therapy; recommended before each course. ■ Evaluation of cardiac function by medical history and physical exam is recommended before each dose; see Precautions. ■ Monitor closely for S/S of hemorrhage or infection; may be life threatening. ■ Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Determine absolute patency of vein. A stinging or burning sensation indicates extravasation; discontinue injection and use another vein. Severe cellulitis and tissue necrosis will result from extravasation with conventional daunorubicins; has not been observed with DaunoXome. ■ Prophylactic antiemetics may reduce nausea and vomiting and increase patient comfort. ■ Monitor uric acid levels; maintain hydration; uric acid–lowering drugs (e.g., allopurinol) may be indicated. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood).

Conventional Daunorubicin:

May cause acute congestive heart failure with total cumulative doses over 550 mg/M^2 in adults (400 mg/M^2 if previous treatment with doxorubicin or radiation therapy in area of heart), 300 mg/M^2 in pediatric patients over 2 years of age, and 10 mg/kg in pediatric patients under 2 years of age.

DaunoXome:

May also cause cardiomyopathy. Monitoring of LVEF recommended at total cumulative doses of 320 mg/M^2, 480 mg/M^2, and every 240 mg/M^2 thereafter.

Patient Education:

Effective birth control recommended. ■ Report IV site burning or stinging promptly. ■ Secondary leukemias have been reported. ■ See Appendix D, p. 1311.

Maternal/Child:

All Daunorubicins:

Category D: can cause fetal harm. Avoid pregnancy. ■ Safety for use in breast-feeding not established; discontinue breast-feeding. ■ Cardiotoxicity may be more frequent and occur at lower cumulative doses in pediatric patients. ■ See Monitor.

DaunoXome:

Safety for use in pediatric patients not established.

Elderly:

Cardiotoxicity and myelotoxicity may be more severe. Consider age-related renal impairment. Safety of DaunoXome for use in the elderly has not been established.

DRUG/LAB INTERACTIONS

Concurrent use with **cyclophosphamide** may increase cardiotoxicity. ■ Dose reduction may be required with concurrent use of **other myelosuppressive agents.** ■ Concurrent use with **hepatotoxic agents** (e.g., high-dose methotrexate) may increase risk of toxicity. ■ Risk of cardiotoxicity increased in patients previously treated with maximum cumulative doses of **other anthracyclines** (e.g., doxorubicin, idarubicin) **and/or radiation encompassing the heart.** ■ Do not administer **vaccines or chloroquine** to patients receiving antineoplastic drugs. ■ See

Precautions.

SIDE EFFECTS

All Daunorubicins:

Bone marrow suppression and cardiotoxicity are dose related and dose limiting.

Conventional Daunorubicin:

Acute congestive heart failure, alopecia (reversible), bone marrow suppression (marked with average doses), chills, decrease in systolic ejection fraction, depressed QRS voltage, diarrhea, fever, gonadal suppression, mucositis, myocarditis, nausea, pericarditis, skin rash, vomiting.

DaunoXome:

Granulocytopenia is most common. Symptoms common to conventional daunorubicin may also occur. Infusion-related back pain, chest tightness, and flushing may be related to liposomal formulation.

Overdose:

Will cause increased severity of myelosuppression, fatigue, nausea, and vomiting.

ANTIDOTE

Most side effects will be tolerated or treated symptomatically. Keep physician informed. Close monitoring of cumulative dosage, bone marrow, ECG, chest x-ray, echocardiography, and systolic ejection fraction may prevent most serious and potentially fatal side effects. There is no specific antidote. Supportive therapy as indicated will help sustain the patient in toxicity. Administration of whole blood products (e.g., packed RBCs, platelets, leukocytes) and/or blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. For extravasation, aspirate as much infiltrated drug as possible, flood site with normal saline, and inject hydrocortisone sodium succinate or hyaluronidase throughout extravasated tissue. Use a 27- or 25-gauge needle. Cold, moist compresses may be helpful; elevate extremity. Site should be observed promptly by a reconstructive surgeon.

DECITABINE FOR INJECTION

(deh-**SIGHT**-ah-been for in-**JEK**-shun)
Dacogen
Antineoplastic (miscellaneous)
pH 6.7 to 7.3

USUAL DOSE

Pretreatment:

Verify pregnancy status. Baseline studies indicated; see Monitor.

There are two treatment options (a 3-day regimen and a 5-day regimen). With either regimen, treatment for a minimum of 4 cycles is recommended. A complete or partial response may take longer than 4 cycles.

Premedication:

Standard antiemetic therapy is indicated.

Decitabine: Option 1 (3-day regimen):

15 mg/M² as an infusion over 3 hours. Repeat every 8 hours for 3 days. Repeat this complete cycle every 6 weeks. See Dose Adjustments and Monitor.

Option 2 (5-day regimen):

20 mg/M² as an infusion over 1 hour. Repeat once each day for 5 days. Repeat this complete cycle every 4 weeks. See Dose Adjustments and Monitor.

DOSE ADJUSTMENTS

Option 1 and Option 2:

Hematologic recovery to at least an ANC equal to or greater than 1,000 cells/mm³ and platelets equal to or greater than 50,000 cells/mm³ is required before subsequent cycles are administered. ■ If a SCr equal to or greater than 2 mg/dL, an ALT or a total bilirubin equal to or greater than 2 times the ULN, and/or an active or uncontrolled infection occur, do not restart decitabine therapy until the toxicity is resolved. ■ No additional dose reductions are indicated based on age, gender, or race; see Precautions and Elderly. ■ If hematologic recovery from a previous decitabine cycle requires more than 6 weeks but less than 8 weeks, delay repeat cycle of decitabine for up to 2 weeks. When therapy is restarted, reduce dose for that cycle to 11 mg/M² every 8 hours (33 mg/M²/day, 99 mg/M²/cycle). ■ If hematologic recovery from a previous decitabine cycle requires more than 8 weeks but less than 10 weeks, assess the patient for disease progression (by bone marrow aspirates). If disease progression has not occurred, delay repeat cycle of decitabine for up to 2 more weeks to allow for hematologic recovery. When therapy is restarted, reduce dose for that cycle to 11 mg/M² every 8 hours (33 mg/M²/day, 99 mg/M²/cycle). In subsequent cycles, maintain or increase dose based on hematologic recovery.

DILUTION

Specific techniques required; see Precautions**.** Temperature of the diluent (NS or D5W) depends on time of administration and preparation.

If decitabine will be used within 15 minutes of preparation:

Reconstitute a single vial (50 mg) with 10 mL of room temperature SWFI (each mL contains 5 mg of decitabine at a pH of 6.7 to 7.3). Further dilute immediately with room temperature NS or D5W to a final concentration of 0.1 to 1 mg/mL (further dilute each mL with 4 mL additional diluent for a 1 mg/mL concentration or 49 mL for a 0.1 mg/mL concentration). Must be used within 15 minutes of reconstitution.

If decitabine will not be used within 15 minutes of reconstitution:

Decitabine must be reconstituted with room temperature SWFI and further diluted using cold (2° to 8° C) infusion fluids (NS or D5W) to a final concentration as above and stored at 2° to 8° C (36° to 46° F) for up to a maximum of 4 hours.

Filters:

Specific information not available.

Storage:

Store unopened vials at 25° C (77° F); excursions permitted to 15° to 30° C (59° to 86° F). Use of reconstituted and/or diluted solution within 15 minutes of reconstitution is preferred or a specific process is required; see Dilution. Use the diluted, refrigerated solution within 4 hours from the time of preparation or discard.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Option 1:

A single dose as an infusion equally distributed over 3 hours.

Option 2:

A single dose as an infusion equally distributed over 1 hour.

ACTIONS

A hypomethylating antineoplastic agent. Cytotoxic to proliferating cells through a process that incorporates it into DNA, inhibits the enzyme DNA methyltransferase, and causes hypomethylation of DNA, leading to cell disintegration and/or death. This hypomethylation in neoplastic cells may restore normal function to genes that are critical for the control of cellular differentiation and proliferation and allow the formation of normal RBCs and platelets. Patients with myelodysplastic syndromes who have responded to decitabine have become transfusion independent. Terminal half-life range is 0.21 to 0.82 hours. Extensively metabolized by an unknown route(s). Protein binding is negligible.

INDICATIONS AND USES

Treatment of patients with myelodysplastic syndromes (MDS), including previously treated and untreated *de novo* and secondary MDS of all French-American-British subtypes (refractory anemia, refractory anemia with ringed sideroblasts, refractory anemia with excess blasts, refractory anemia with excess blasts in transformation, and chronic myelomonocytic leukemia) and intermediate-1, intermediate-2, and high-risk

International Prognostic Scoring System groups.

CONTRAINDICATIONS

Manufacturer states, “None.”

PRECAUTIONS

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Administered by or under the direction of a physician specialist in a facility with adequate diagnostic and treatment facilities to monitor the patient and respond to any medical emergency. ■ The effects of age, gender, race, or renal or hepatic impairment on the pharmacokinetics of decitabine have not been studied. ■ Fatal and serious myelosuppression occurs in decitabine-treated patients. ■ Myelosuppression and worsening neutropenia may occur more frequently in the first or second treatment cycles and may not indicate progression of underlying MDS. Neutropenia and thrombocytopenia may be dose-limiting toxicities. ■ Patients with MDS produce poorly functioning and immature blood cells and experience anemia, bleeding, fatigue, infection, and weakness. High-risk MDS patients may experience bone marrow failure, which may lead to death from bleeding and infection. ■ MDS can progress to acute leukemia (AML). ■ Use caution in patients with renal or hepatic impairment; monitor more frequently for excessive toxicity. Use has not been studied.

Monitor:

Obtain a baseline CBC with platelets and monitor before each dosing cycle and as indicated between cycles. ■ Mange toxicity using dose-delay, dose-reduction, growth factors, and anti-infective therapies as needed. ■ Obtain a baseline and monitor renal and hepatic function (BUN, SCr, bilirubin) as indicated. ■ Use prophylactic antiemetics to reduce nausea and vomiting and increase patient comfort. ■ Monitor for S/S of infection. Prophylactic antibiotics may be indicated pending results of C/S in a febrile neutropenic patient. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Avoid administration of live virus vaccine to immunocompromised patients. ■ Observe for S/S of a hypersensitivity reaction; specific information not available. ■ See Precautions and Antidote.

Patient Education:

Avoid pregnancy; effective birth control recommended for both males and females; see Maternal/Child. Women should report a suspected pregnancy immediately. ■ Discuss possible liver or kidney disease with a health care professional. ■ Report S/S of infection (e.g., fever, sore throat), bruising, bleeding, or other suspected side effects.

Maternal/Child:

Avoid pregnancy; may cause fetal harm. Women of childbearing potential should avoid becoming pregnant and use effective contraception while receiving decitabine and for 6 months after the last dose. Males with female partners of reproductive potential should use effective contraception while receiving treatment with decitabine and for 3 months after the last dose. ■ Avoid breast-feeding during treatment with decitabine and for at least 1 week after the last dose. ■ Safety and effectiveness for use in pediatric patients not established.

Elderly:

The majority of patients in clinical trials were over 65 years of age. Safety and effectiveness similar to younger adults; however, greater sensitivity of some older individuals should be considered.

DRUG/LAB INTERACTIONS

Formal drug interactions studies have not been completed. In vitro studies suggest that decitabine is unlikely to inhibit or induce the activities of cytochrome P_{450} isoenzymes. ■ Plasma protein binding is negligible; interactions due to displacement of more highly protein bound drugs from plasma proteins are not expected. ■ Do not administer **live virus vaccines** to immunocompromised patients who are receiving antineoplastic agents.

SIDE EFFECTS

Cough, constipation, diarrhea, fatigue, fever, hyperglycemia, nausea, and petechiae have been reported most commonly. Bone marrow suppression (anemia, neutropenia, thrombocytopenia) was the most frequent cause of dose reduction, delay, and discontinuation. Grade 3 or 4 adverse events included febrile neutropenia, leukopenia, neutropenia, and thrombocytopenia. During clinical trials, therapy was also discontinued because of abnormal liver function tests, cardiopulmonary arrest, intracranial hemorrhage, *Mycobacterium avium* complex infection, and pneumonia. Atrial fibrillation, central line infection, febrile neutropenia, neutropenia, and pulmonary edema also resulted in delayed doses; bone marrow suppression (anemia, neutropenia, thrombocytopenia), depression, edema, lethargy, pharyngitis, and tachycardia resulted in reduced doses. Numerous other side effects may occur.

Post-Marketing:

Acute febrile neutrophilic dermatosis (Sweet's syndrome) has been reported.

Overdose:

Increased myelosuppression, including prolonged neutropenia and thrombocytopenia.

ANTIDOTE

Notify physician of any side effects. Most will be treated symptomatically. Dosage may be delayed for hematologic toxicity. Hematologic recovery to at least an ANC equal to or greater than 1,000 cells/mm^3 and platelets equal to or greater than 50,000 cells/mm^3 between cycles is required; see Dose Adjustments. If a SCr equal to or greater than 2 mg/dL, an ALT or a total bilirubin equal to or greater than 2 times the ULN, and/or an uncontrolled infection occur, discontinue decitabine therapy until the toxicity is resolved. Blood and blood products, antibiotics, and other adjunctive therapies must be available. Blood modifiers (e.g., darbepoetin alfa, epoetin alfa, filgrastim, pegfilgrastim, sargramostim) may be indicated to treat bone marrow toxicity. No known antidote; provide supportive care in overdose. ■ Resuscitate as necessary.

DEFEROXAMINE MESYLATE

(deh-fer-**OX**-ah-meen **MES**-ih-layt)
Desferal
Antidote
Chelating agent
pH 4 to 6

USUAL DOSE

Acute iron intoxication in adults and pediatric patients over 3 years of age:

IM use preferred for all patients not in shock; see Precautions. Administer an initial dose of 1,000 mg at a rate not to exceed 15 mg/kg/hr. May be followed with 500 mg every 4 hours for 2 doses at a rate not to exceed 125 mg/hr (adults) or 15 mg/kg/hr (pediatric patients). Depending on clinical response, subsequent doses of 500 mg every 4 to 12 hours may be administered. ***Do not exceed 6 Gm in 24 hours by way of any or all routes—IV, IM, clysis, or oral.*** As soon as clinical condition permits, IV route should be changed to IM.

Chronic iron overload in adults:

40 to 50 mg/kg/day over 8 to 12 hours for 5 to 7 days per week. Average dose should not exceed 60 mg/kg/day. Alternately, 500 to 1,000 mg daily may be given as an IM injection. In poorly compliant patients, deferoxamine may be administered *before or following* same-day blood transfusion (e.g., 1,000 mg over 4 hours on the day of transfusion); however, the contribution to iron balance is limited. Should not be administered concurrently with blood to avoid confusion about the source of side effects (e.g., anaphylaxis, hypotension, rash).

Aluminum toxicity (unlabeled):

Dose must be individualized. One source recommends 5 to 10 mg/kg 4 to 6 hours before dialysis. May repeat every 7 to 10 days as needed. 100 mg can bind 4.1 mg of aluminum.

PEDIATRIC DOSE

Acute iron intoxication in pediatric patients over 3 years of age:

See Usual Dose. ***Do not exceed a rate of 15 mg/kg/hr or a total dose of 6 Gm in 24 hours.***

Chronic iron overload:

20 to 40 mg/kg/day over 8 to 12 hours for 5 to 7 days per week. Average dose should not exceed 40 mg/kg/day until growth has ceased. ***Do not exceed a rate of 15 mg/kg/hr or a total dose of 6 Gm in 24 hours.***

DOSE ADJUSTMENTS

Dose selection should be cautious in the elderly based on the potential for decreased organ function and concomitant disease or drug therapy.

DILUTION

Each 500 mg must be reconstituted in 5 mL of SWFI. When completely dissolved, deferoxamine must be further diluted in an IV solution; ½NS, NS, D5W, D10W, and LR are **compatible.** Dissolve completely before use.

Storage:

Store unopened vial at room temperature. Reconstituted solution may be stored at room temperature for 24 hours if it has been prepared in a sterile laminar flow hood. Do not refrigerate reconstituted solution. Single-dose vial. Discard unused portion of vial.

COMPATIBILITY

Manufacturer states, "Reconstituting in solvents or under conditions other than indicated may result in precipitation. Turbid solutions should not be used."

RATE OF ADMINISTRATION

Initial 1,000 mg may be administered at a rate not to exceed 15 mg/kg/hr. Follow with 500 mg over 4 hours for 2 doses. Depending on clinical response, subsequent 500-mg doses may be given over 4 to 12 hours. In these subsequent doses, do not exceed a rate of 125 mg/hr (adults) or 15 mg/kg/hr (pediatric patients); see Precautions, Side Effects, Overdose.

ACTIONS

A heavy metal antagonist that chelates iron and aluminum. As an iron-chelating agent, deferoxamine complexes with iron to form ferrioxamine, a stable chelate that prevents the iron from entering into further chemical reactions. Chelates iron from ferritin and hemosiderin but not readily from transferrin, hemoglobin, or cytochromes. 1 Gm of deferoxamine can theoretically sequester 85 mg of iron (as the ferric ion); however, the rate of complex formation is pH dependent. Metabolized by plasma enzymes via unknown pathways. Chelate is readily soluble in water and passes easily through the kidneys, giving the urine a characteristic reddish color. Also excreted in feces through the bile.

INDICATIONS AND USES

To facilitate the removal of iron in the treatment of acute iron intoxication. Is an adjunct to, not a substitute for, standard measures used to treat acute iron intoxication. Such measures may include induction of emesis and/or gastric lavage; suction and maintenance of a clear airway; control of shock with IV fluids, blood, oxygen, and vasopressors; and correction of acidosis. ■ Treatment of chronic iron overload due to transfusion-dependent anemias.

Limitation of use:

Not indicated for primary hemochromatosis; phlebotomy is the method of choice for removing excess iron in the blood.

Unlabeled uses:

Diagnosis and management of aluminum toxicity associated with chronic kidney disease (CKD).

CONTRAINDICATIONS

Severe renal disease or anuria. ■ Hypersensitivity to deferoxamine.

PRECAUTIONS

IM administration is preferred and should be used for all patients not in shock. May be given SC by hypodermoclysis. IV administration should be used only in a state of cardiovascular shock or chronic iron overload and then only by slow IV infusion. Flushing, urticaria, hypotension, and shock have occurred with rapid infusion. ■ Ocular and auditory disturbances have been reported with high doses, in patients with low ferritin levels, or when the drug is administered over a prolonged period of time. Disturbances may be reversible with early detection and immediate cessation of therapy. ■ Increases in SCr, renal tubular disorders, and acute renal failure have been reported. ■ High doses in patients with concomitant low ferritin levels have been associated with growth retardation. Growth velocity may partially resume to pretreatment rates with dose reduction; see Maternal/Child. ■ Acute respiratory distress syndrome (ARDS) has been reported following treatment with excessively high intravenous doses in patients with acute iron intoxication or thalassemia. ■ Rare cases of mucormycosis (some fatal) and generalized infections with *Yersinia enterocolitica* and *Yersinia pseudotuberculosis* have been reported. Discontinue therapy, obtain cultures, and institute proper therapy at first sign of infection. ■ Impairment of cardiac function has been reported following concomitant treatment with deferoxamine and vitamin C (more than 500 mg daily). However, patients with chronic iron overload may become vitamin C deficient. Cautious vitamin C supplementation may be required. Begin supplementation only after initial month of deferoxamine therapy. Limit daily dose to 200 mg given in divided doses. Avoid concomitant use of vitamin C and deferoxamine in patients with pre-existing cardiac failure. ■ Treatment with deferoxamine in the presence of aluminum overload may result in decreased serum calcium and aggravation of hyperparathyroidism. In patients with aluminum-related encephalopathy who are undergoing dialysis, deferoxamine may cause neurologic dysfunction (seizures). May precipitate onset of dialysis dementia. ■ Studies have not been performed in patients with impaired hepatic function. ■ See Drug/Lab Interactions.

Monitor:

Deferoxamine is adjunctive therapy; see Precautions for standard measures for treating acute iron intoxication. ■ Monitor for development of ocular disturbances. May include blurred vision; development of cataracts after prolonged administration in chronic iron overload; decreased visual acuity (including vision loss; vision defects; scotoma; impaired peripheral, color, and night vision; optic neuritis; cataracts; corneal opacities; and retinal pigmentary abnormalities). Periodic visual acuity tests, slit-lamp examinations, and funduscopy are recommended with prolonged therapy. ■ Monitor for development of auditory disturbances. May include tinnitus and hearing loss, including high-frequency sensorineural hearing loss. Periodic audiometry is recommended with prolonged therapy. ■ Monitor cardiac function in patients receiving concomitant therapy with vitamin C and deferoxamine. Cardiac dysfunction may be reversible with discontinuation of vitamin C. ■ Monitor serum ferritin and serum iron. ■ In acute iron intoxication, larger-than-normal amounts of IV fluids are required to maintain intravascular volume and prevent kidney damage. Monitor renal function. ■ Monitor blood gases, central venous pressure (CVP), and cardiac output as indicated to assess the effects of absorbed iron.

Patient Education:

Report any hearing or vision changes. ■ Do not take vitamin C unless prescribed by physician. ■ Do not drive or operate hazardous machinery if dizziness, visual or auditory impairment, or other nervous system disturbances are experienced. ■ May cause reddish discoloration of urine.

Maternal/Child:

Category C: use only if potential benefit justifies potential risk to fetus. ■ Use caution during breast-feeding. ■ Safety and effectiveness for use in pediatric patients under 3 years of age not established. ■ Monitor body weight and growth every 3 months in pediatric patients; see Precautions. ■ Supplementation may be required in pediatric patients who become vitamin C deficient. In general, 50 mg daily is sufficient for pediatric patients under 10 years of age. 100 mg is sufficient in older pediatric patients; see Precautions and Drug/Lab Interactions.

Elderly:

See Dose Adjustments and Drug/Lab Interactions. ■ Risk of cardiac decompensation increased. ■ Post-marketing reports suggest a possible increased risk of eye disorders (color blindness, maculopathy, and scotoma) and an increased risk of hearing loss or deafness.

DRUG/LAB INTERACTIONS

Risk of cardiac decompensation is increased when given concurrently with large doses (greater than 200 mg) of **vitamin C** (ascorbic acid). However, vitamin C increases the availability of iron for chelation. Small doses of a vitamin C supplement may be required. ■ Concurrent treatment with **prochlorperazine** may lead to a temporary impairment in consciousness. ■ Discontinue deferoxamine 48 hours before

scintigraphy with gallium-67. Imaging results may be distorted because of rapid urinary excretion of deferoxamine-bound gallium-67.

SIDE EFFECTS

Occur more frequently with too-rapid administration; abdominal discomfort, acute respiratory distress syndrome (ARDS), arthralgia, diarrhea, dysuria, fever, flushing of the skin, growth retardation and bone changes, headache, high-frequency sensorineural hearing loss and/or tinnitus, hypersensitivity reactions (anaphylaxis, angioedema, generalized rash, urticaria), hypotension, impaired hepatic and/or renal function, increased ALT and AST, infection (mucormycosis, *Yersinia*), injection site reactions, muscle spasms, myalgia, nausea, neurologic disturbances (dizziness; peripheral sensory, motor, or mixed neuropathy; paresthesias; exacerbation or precipitation of aluminum-related dialysis encephalopathy), seizures, shock, tachycardia, visual disturbances (blurred vision, decreased acuity or loss of vision, retinopathy, scotoma, and others). Blood dyscrasias (e.g., leukopenia, thrombocytopenia) have been reported. See Precautions.

Post-Marketing:

Increased SCr, acute renal failure, and renal tubular disorders.

Overdose:

Acute transient loss of vision, acute renal failure, agitation, aphasia, bradycardia, CNS depression including coma, headache, hypotension, GI disturbances, nausea, and tachycardia may occur with too-rapid administration, inadvertent IV bolus, or overdose.

Post-Marketing:

Renal dysfunction (e.g., increased SCr, renal tubular disorders, acute renal failure).

ANTIDOTE

At first sign of side effects, decrease rate of administration. If side effects persist, discontinue drug and notify physician. Further dilution and decrease in rate of administration may be necessary. Readily dialyzable. Resuscitate as indicated.

DEFIBROTIDE

(de-**FYE**-broe-tide)
Defitelio
Antiplatelet agent
Thrombolytic agent
pH 6.8 to 7.8

USUAL DOSE

Pretreatment:

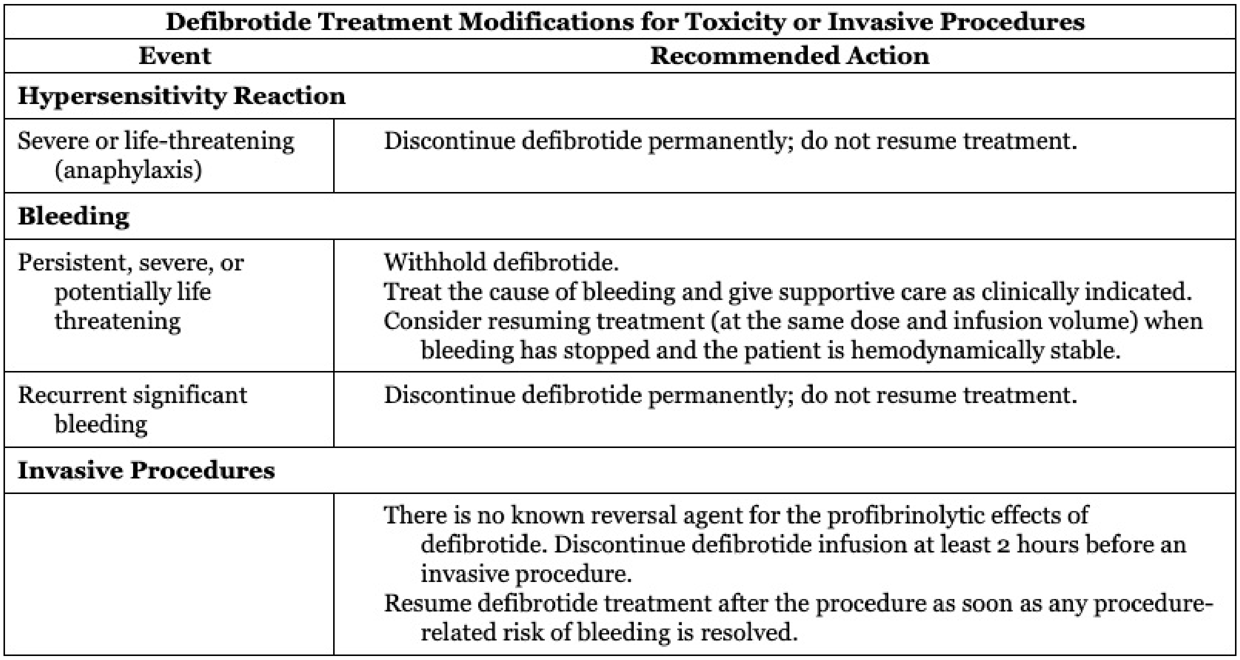
Adult and pediatric patients: Before administration, confirm that the patient is not experiencing clinically significant bleeding and is hemodynamically stable on no more than one vasopressor.

Defibrotide:

6.25 mg/kg every 6 hours given as a 2-hour infusion. Base dose on patient's baseline body weight, which is defined as the patient's weight before the preparative regimen for hematopoietic stem cell transplantation (HSCT). Administer for a minimum of 21 days. If after 21 days S/S of veno-occlusive disease (VOD) have not resolved, continue defibrotide until resolution of VOD or up to a maximum of 60 days.

DOSE ADJUSTMENTS

Treatment modification, including temporary or permanent discontinuation, is outlined in the following chart.



Defibrotide Treatment Modifications for Toxicity or Invasive Procedures	
Event	**Recommended Action**
Hypersensitivity Reaction	
Severe or life-threatening (anaphylaxis)	Discontinue defibrotide permanently; do not resume treatment.
Bleeding	
Persistent, severe, or potentially life threatening	Withhold defibrotide. Treat the cause of bleeding and give supportive care as clinically indicated. Consider resuming treatment (at the same dose and infusion volume) when bleeding has stopped and the patient is hemodynamically stable.
Recurrent significant bleeding	Discontinue defibrotide permanently; do not resume treatment.
Invasive Procedures	
	There is no known reversal agent for the profibrinolytic effects of defibrotide. Discontinue defibrotide infusion at least 2 hours before an invasive procedure. Resume defibrotide treatment after the procedure as soon as any procedure-related risk of bleeding is resolved.

DILUTION

Available in a 200 mg/2.5 mL (80 mg/mL) single-patient-use vial; a clear and light yellow to brown solution. Determine the dose based on patient's baseline weight, which is defined as the patient's weight before the preparative regimen for hematopoietic stem cell transplantation (HSCT). Calculate the volume of defibrotide needed and withdraw this amount from the vial(s). Add this volume to an infusion bag containing NS or D5W. Final concentration of the prepared solution should be 4 to 20 mg/mL. Mix gently.

Filter:

0.2-micron in-line filter required.

Storage:

Store unopened vials at CRT. Diluted solution should be used within 4 hours if stored at room temperature or within 24 hours if stored under refrigeration. Up to 4 doses of defibrotide may be prepared at one time if refrigerated. Discard any partially used vials.

COMPATIBILITY

Manufacturer states, “Do not coadminister Defitelio and other intravenous drugs concurrently within the same intravenous line.”

RATE OF ADMINISTRATION

Administer using an infusion set equipped with a 0.2-micron in-line filter. Flush the IV administration line with NS or D5W immediately before and after administration.

Administer each single dose as a constant infusion equally distributed over 2 hours.

ACTIONS

An oligonucleotide mixture with profibrinolytic properties. The mechanism of action of defibrotide has not been fully elucidated. In vitro, it enhances the enzymatic activity of plasmin to hydrolyze fibrin clots. It also increases tissue plasminogen activator (t-PA) and thrombomodulin expression and decreases von Willebrand factor (vWF) and plasminogen activator inhibitor-1 (PAI-1) expression, thereby reducing endothelial cell (EC) activation and increasing endothelial cell–mediated fibrinolysis. Highly bound to plasma proteins. Metabolism followed by urinary excretion is likely the main route of elimination. The exact pathway of metabolism is unknown, but in vitro studies show that defibrotide does not undergo appreciable metabolism by hepatocyte cells. Half-life is less than 2 hours.

INDICATIONS AND USES

Treatment of adult and pediatric patients with hepatic VOD, also known as sinusoidal obstruction syndrome (SOS), with renal or pulmonary dysfunction after HSCT.

CONTRAINDICATIONS

Concomitant administration with systemic anticoagulant or fibrinolytic therapy. ■ Known hypersensitivity to defibrotide or to any of its excipients.

PRECAUTIONS

May increase the risk of bleeding in patients with VOD after HSCT. Do not initiate defibrotide in patients with active bleeding. Withhold or discontinue defibrotide in patients who develop bleeding. Treat the underlying cause and provide supportive care until the bleeding has stopped; see Dose Adjustments. ■ Hypersensitivity reactions have been reported. Anaphylaxis was reported in a patient who had previously received defibrotide. ■ See Drug/Lab Interactions.

Monitor:

Monitor patient for signs of bleeding. ■ Monitor for S/S of a hypersensitivity reaction, especially if there is a history of previous exposure to defibrotide. Reported hypersensitivity reactions have included anaphylaxis, angioedema, rash, and urticaria.

Patient Education:

May increase the risk of hemorrhage. Promptly report any S/S of bleeding (e.g., altered vision, blood in urine or stool, confusion, easy bruising, headache, slurred speech, or unusual bleeding). ■ Inform health care provider of any previous defibrotide use. ■ Promptly report S/S of a hypersensitivity reaction (e.g., itching, hives, rash, shortness of breath, wheezing).

Maternal/Child:

Information on use during pregnancy and breast-feeding is not available. Animal studies suggest a potential risk of miscarriage if administered during pregnancy. ■ Because of the risk of serious adverse reactions, including bleeding in a breast-fed infant, breast-feeding is not recommended during treatment with defibrotide. ■ Safety and effectiveness have been established in pediatric patients.

Elderly:

Studies did not include sufficient numbers of subjects 65 years of age and older to determine whether they respond differently than younger subjects. Differences in response have not been identified.

DRUG/LAB INTERACTIONS

Concomitant use with a **systemic anticoagulant** (e.g., apixaban [Eliquis], heparin, rivaroxaban [Xarelto], warfarin [Coumadin]) or **fibrinolytic therapy** (e.g., alteplase [Activase], tenecteplase [TNKase]), not including use for routine maintenance or reopening of central venous lines, may increase the risk of bleeding. Discontinue anticoagulants and fibrinolytic agents before defibrotide treatment, and consider delaying the start of defibrotide administration until the effects of the anticoagulant have abated; see Contraindications. ■ May enhance the pharmacodynamic activity of **antithrombotic/fibrinolytic drugs** such as heparin or alteplase. Concomitant use is contraindicated because of an increased risk of hemorrhage. ■ In vitro studies demonstrate that defibrotide does not induce (CYP1A2, CYP2B6, CYP3A4, UGT1A1) or inhibit (CYP1A2, CYP2B6, CYP3A4, CYP2C8, CYP2C9, CYP2C19, CYP2D6, UGT1A1, UGT2B7) the major drug-metabolizing enzymes and is not a substrate or inhibitor of the major drug uptake transporters (OAT1, OAT3, OCT1, OCT2, OATP1B1, OATP1B3) or efflux transporters (P-gp and BCRP).

SIDE EFFECTS

The most common adverse reactions were diarrhea, epistaxis, hypotension, nausea, and vomiting. The most common serious adverse reactions were hypotension and pulmonary alveolar hemorrhage. Other reported adverse reactions included cerebral hemorrhage, gastrointestinal hemorrhage, graft-versus-host disease, hyperuricemia, infection, intracranial hemorrhage, lung infiltration, pneumonia, pulmonary hemorrhage, and sepsis.

ANTIDOTE

Notify physician of any side effects; most will be treated symptomatically. Discontinue defibrotide if bleeding develops. Treat underlying cause and provide supportive care as indicated. Discontinue defibrotide if a severe hypersensitivity reaction occurs. Treat hypersensitivity reactions as indicated (e.g., oxygen, diphenhydramine, epinephrine, corticosteroids, vasopressors, and/or fluids). Resuscitate as necessary. Defibrotide is not removed by hemodialysis.

DELAFLOXACIN BBW

(del-a-**FLOXS**-a-sin)
Baxdela
Antibacterial
(Fluoroquinolone)

USUAL DOSE

Pretreatment:

Baseline studies indicated; see Precautions and Monitor.

Acute bacterial skin and skin structure infections (ABSSSI):

300 mg as an IV infusion over 60 minutes every 12 hours for 5 to 14 days.

Community-acquired bacterial pneumonia (CABP):

300 mg as an IV infusion over 60 minutes every 12 hours for 5 to 10 days. A 300-mg IV dose is equivalent to a 450-mg oral dose. Transfer to oral therapy at the discretion of the physician.

DOSE ADJUSTMENTS

No dose adjustment required in mild to moderate renal impairment (estimated glomerular filtration rate [eGFR] 30 to 89 mL/min/1.73 M^2). ■ Reduce dose to 200 mg IV every 12 hours in severe renal impairment (eGFR 15 to 29 mL/min/1.73 M^2), and transfer to a 450-mg tablet orally every 12 hours at the discretion of the physician. ■ Not recommended for use in end-stage renal disease (ESRD) (eGFR less than 15 mL/min/1.73 M^2), including patients on hemodialysis (information is insufficient to provide dosing recommendations). ■ No dose adjustment required in patients with hepatic impairment.

DILUTION

Available in single-use vials. Reconstitute each 300-mg vial with 10.5 mL of D5W or NS. Shake vial vigorously until contents dissolve completely. Reconstituted vial contains 300 mg per 12 mL (25 mg/mL) as a clear yellow to amber-colored solution. Withdraw the desired dose (12 mL for a 300-mg dose and 8 mL for a 200-mg dose) from the reconstituted solution. Must be further diluted to a total volume of 250 mL with NS or

D5W to achieve a concentration of 1.2 mg/mL for administration.

Filters:

Specific information not available.

Storage:

Before use, store vials at CRT. Reconstituted vials and diluted solution may be refrigerated at 2° to 8° C (36° to 46° F) or stored at 20° to 25° C (68° to 77° F) for up to 24 hours. Do not freeze. Discard unused solution.

COMPATIBILITY

Manufacturer states, “Do NOT administer delafloxacin for injection through the same IV line with any solution containing multivalent cations (e.g., calcium and magnesium). Do NOT co-infuse delafloxacin with other medications.”

RATE OF ADMINISTRATION

Administer each 300- or 200-mg dose as an IV infusion equally distributed over 60 minutes. May be given through a Y-tube or three-way stopcock of infusion set. Temporarily discontinue other solutions infusing at the same site, and flush tubing with D5W or NS before and after delafloxacin; see Compatibility.

ACTIONS

A fluoroquinolone antibacterial drug. Antibacterial activity is due to the inhibition of both bacterial topoisomerase IV and DNA gyrase (topoisomerase II), enzymes that are required for bacterial DNA replication, transcription, repair, and recombination. Exhibits a concentration-dependent bactericidal activity against gram-positive and gram-negative bacteria in vitro. AUC comparable for IV and oral doses. 84% protein bound, primarily to albumin. Metabolized predominantly by glucuronidation. Mean half-life is 3.7 hours. Excreted as unchanged drug and glucuronide metabolites in urine and feces.

INDICATIONS AND USES

Treatment of adults with infections caused by susceptible strains of designated microorganisms in conditions listed in this section.

Treatment of acute bacterial skin and skin structure infections (ABSSSI). ■ Treatment of adults with community-acquired bacterial pneumonia (CABP).

CONTRAINDICATIONS

Known hypersensitivity to delafloxacin, any of its components, or any of the fluoroquinolone class of antibacterial drugs.

PRECAUTIONS

For IV use only. ■ To reduce the development of drug-resistant bacteria and maintain its effectiveness, delafloxacin should be used to treat only those infections proven or strongly suspected to be caused by bacteria. Prescribing delafloxacin in the absence of a proven or strongly suspected bacterial infection is unlikely to provide benefit to the patient and increases the risk of development of drug-resistant bacteria. ■ Culture and sensitivity studies indicated to determine susceptibility of the causative organism to delafloxacin. ■ Cross-resistance between delafloxacin and other fluoroquinolone-class antibacterial agents has been observed; however, some isolates resistant to other fluoroquinolones may be susceptible to delafloxacin. ■ Prolonged use may cause superinfection because of overgrowth of nonsusceptible organisms. ■ Fluoroquinolones have been associated with disabling and potentially irreversible serious adverse reactions that have occurred together in the same patient. Commonly seen adverse reactions include tendinitis and tendon rupture, arthralgia, myalgia, peripheral neuropathy, and CNS effects (e.g., anxiety, confusion, depression, hallucinations, insomnia, severe headaches). These reactions can occur within hours to weeks after starting delafloxacin and have been seen in patients of any age and in patients without any pre-existing risk factors. Discontinue delafloxacin immediately and avoid the use of fluoroquinolones in patients who experience any of these serious adverse reactions. ■ Fluoroquinolones have been associated with an increased risk of tendinitis and tendon rupture in all ages. Most frequently involves the Achilles tendon but has also been reported with the shoulder, hand, biceps, thumb, and other tendon sites. ■ Tendon rupture or tendinitis may occur within hours of starting a fluoroquinolone or as long as several months after completion of fluoroquinolone therapy and may occur bilaterally. Risk may be increased in patients over 60 years of age, in patients taking corticosteroids, and in patients with heart, kidney, or lung transplants. Other risk factors include strenuous physical activity, renal failure, and previous tendon disorders such as rheumatoid arthritis. Avoid delafloxacin in patients who have a history of tendon disorders or have experienced tendinitis or tendon rupture. Discontinue delafloxacin immediately if patient experiences pain, swelling, inflammation, or rupture of a tendon. ■ Fluoroquinolones have been associated with an increased risk of peripheral neuropathy. Cases of sensory or sensorimotor axonal polyneuropathy resulting in paresthesias, hypoesthesias, dysesthesias (impairment of sensitivity or touch), or weakness have been reported. Symptoms may occur soon after initiation of therapy and may be irreversible. To minimize the development of an irreversible condition, discontinue delafloxacin if the patient experiences symptoms of peripheral neuropathy, including pain, burning, tingling, numbness, and/or weakness or other alterations of sensation, including light touch, pain, temperature, position sense, and vibratory sensation and/or motor strength. Avoid delafloxacin in patients who have previously experienced peripheral neuropathy. ■ Fluoroquinolones, including delafloxacin, have been associated with an increased risk of seizures (convulsions), increased intracranial pressure (pseudotumor cerebri), tremors, and light-headedness. May trigger seizures or lower the seizure threshold. Use caution in patients with epilepsy or known or suspected CNS disorders that may predispose patients to seizures or lower the seizure threshold (e.g., severe cerebral arteriosclerosis, previous history of convulsions, reduced cerebral blood flow, altered brain structure, or stroke) or in the presence of other risk factors that may predispose patients to seizures (e.g., drugs that may lower the seizure threshold, renal dysfunction). ■ Fluoroquinolones, including delafloxacin, have been associated with an increased risk of psychiatric adverse reactions, including toxic psychosis; psychotic reactions progressing to suicidal ideations/thoughts, hallucinations, paranoia; depression; or self-injurious behavior such as attempted or completed suicide; anxiety, agitation, restlessness or nervousness; confusion, delirium, disorientation, or disturbances in attention; insomnia or nightmares; and memory impairment. These reactions may occur after the first dose. ■ Fluoroquinolones have neuromuscular blocking activity and may exacerbate muscle weakness in persons with myasthenia gravis. Serious adverse events, including a requirement for ventilatory support and deaths, have been reported in these patients. Avoid use in patients with a known history of myasthenia gravis. ■ Serious and occasionally fatal hypersensitivity and/or anaphylactic reactions have been reported and may occur after the first dose. ■ *Clostridium difficile*–associated diarrhea (CDAD) has been reported. May range from mild diarrhea to fatal colitis. Consider in patients who present with diarrhea during or after treatment with delafloxacin. ■ Epidemiologic studies report an increased rate of aortic aneurysm and dissection within 2 months after use of fluoroquinolones, particularly in elderly patients. In patients with a known aortic aneurysm or in patients who are at greater risk for aortic aneurysms, delafloxacin use should be limited to cases in which there are no alternative antibacterial treatments available. ■ Fluoroquinolones, including delafloxacin, have been associated with disturbances of blood glucose, including symptomatic hyperglycemia and hypoglycemia, usually in diabetic patients receiving concomitant treatment with an oral hypoglycemic agent (e.g., glyburide) or with insulin. In these patients, careful monitoring of blood glucose is recommended. Severe cases of hypoglycemia resulting in coma or death have been reported. ■ Use caution in patients with impaired renal function; see Dose Adjustments.

Monitor:

Obtain baseline CBC with differential, SCr, and blood glucose. Monitor SCr and eGFR, especially in patients with severe renal impairment. If SCr increases, consider switching to delafloxacin tablets, if possible. ■ Monitor for S/S of a hypersensitivity reaction (e.g., airway obstruction, angioedema, cardiovascular collapse, dyspnea, hypotension/shock, itching, loss of consciousness, tingling, urticaria, and other serious skin reactions). May cause anaphylaxis with the first or succeeding doses. Emergency equipment must always be available; see Precautions. ■ Monitor for S/S of peripheral neuropathy. Discontinue delafloxacin at the first symptoms of neuropathy (e.g., pain, burning, tingling, numbness, and/or weakness) or if patient is found to have deficits in light touch, pain, temperature, position sense, vibratory sensation, and/or motor strength. ■ Monitor for S/S of tendinitis or tendon rupture (e.g., tendon pain, swelling, or inflammation). ■ Monitor for S/S of CNS effects (e.g., anxiety, confusion, depression, hallucinations, insomnia, paranoia, seizures). ■ Monitor blood glucose, especially in diabetic patients. ■ Monitor infusion site for inflammation and/or extravasation. ■ See Precautions, Drug/Lab Interactions, and Antidote.

Patient Education:

A patient medication guide is available from the manufacturer. ■ Discontinue delafloxacin and promptly report the development of any severe adverse reaction. ■ Review all medicines and disease history with pharmacist or physician before initiating treatment. ■ Inform physician of any history of myasthenia gravis. ■ Promptly report skin rash or any other hypersensitivity reaction. ■ Discontinue delafloxacin and promptly report tendon pain, swelling or inflammation, weakness, or inability to use a joint. Avoid exercise and use of the affected area. ■ Promptly report pain, burning, tingling, numbness, and/or weakness in extremities. Nerve damage can be permanent. ■ Promptly report development of any CNS side effects (e.g., convulsions, dizziness, light-headedness, change in mood or behavior). ■ Inform physician of any history of seizures. ■ Request assistance with ambulation; may cause dizziness and light-headedness. Use caution in tasks that require alertness. ■ Promptly report diarrhea or bloody stools that occur during treatment or up to several months after an antibiotic has been discontinued; may indicate CDAD and require treatment. ■ Seek emergency medical care if sudden chest, stomach, or back pain is experienced. ■ Diabetic patients taking oral hypoglycemic agents or insulin should discontinue delafloxacin and contact their provider if they experience a hypoglycemic reaction. ■ See Precautions, Monitor, and Antidote.

Maternal/Child:

Safety for use in pregnancy not established; benefits must outweigh risks. ■ Human data on safety during breast-feeding not available. Use caution if breast feeding; consider the mother’s clinical need for delafloxacin and the health benefits to and potential adverse effects on the breast-fed infant. ■ Not recommended for use in pediatric patients under 18 years of age; safety and effectiveness not established.

Elderly:

Safety and effectiveness in elderly patients is similar to that in younger adults; however, they may experience an increased risk of side effects (e.g., aortic aneurysm and dissection, CNS effects, tendinitis, tendon rupture). Monitoring of renal function may be useful. ■ See Dose Adjustments and Precautions.

DRUG/LAB INTERACTIONS

Specific information not available. ■ Should not be coadministered with any solution containing multivalent cations (e.g., magnesium) through the same IV line. ■ In vitro drug combination studies with delafloxacin and aztreonam, ceftazidime, colistin, daptomycin, linezolid, meropenem, tigecycline, trimethoprim/sulfamethoxazole, and vancomycin demonstrated neither synergy nor antagonism.

SIDE EFFECTS

The most common side effects are diarrhea, elevated liver function tests (transaminases), headache, nausea, and vomiting. Serious side effects include CDAD, CNS effects, hypersensitivity reactions, peripheral neuropathy, and tendinitis and tendon rupture. Abdominal pain; abnormal dreams; anxiety; blurred vision; bradycardia; cardiac palpitations; dermatitis; dizziness; dysgeusia; dyspepsia; flushing; fungal infections; hyperglycemia; hypertension; hypoesthesia; hypoglycemia; hypotension; increased alkaline phosphatase, creatinine, creatine phosphokinase; infusion site bruising, discomfort, edema, erythema, extravasation, irritation, pain, phlebitis, swelling, and thrombosis; insomnia; myalgia; oral candidiasis; paresthesia; phlebitis; presyncope; pruritus; rash; renal impairment; renal failure; sinus tachycardia; syncope; tinnitus; urticaria; vertigo; and vulvovaginal candidiasis have been reported in fewer than 2% of patients.

ANTIDOTE

Keep physician informed of all side effects. Most minor side effects will be treated symptomatically; monitor closely. Discontinue delafloxacin at the first sign of any major side effect (CDAD, CNS symptoms, hypersensitivity reactions, symptoms of peripheral neuropathy, or tendon rupture). Treat hypersensitivity reactions as indicated with epinephrine, airway management, oxygen, IV fluids, antihistamines (e.g., diphenhydramine), corticosteroids (e.g., hydrocortisone sodium succinate), and pressor amines (e.g., dopamine). Treat CNS symptoms as indicated. Mild cases of CDAD may respond to discontinuation of delafloxacin. Treat CDAD with fluids, electrolytes, protein supplements, and appropriate antibiotics (e.g., oral vancomycin) as indicated. In severe cases, surgical evaluation may be indicated. Complete rest is indicated for an affected tendon until treatment is available. Treat overdose with observation and general supportive measures; about 19% of delafloxacin is removed by hemodialysis.

DENILEUKIN DIFTITOX BBW

(den-ih-**LOO**-kin **DIF**-tih-tox)
Ontak
Antineoplastic
Biological response modifier
pH 6.9 to 7.2

USUAL DOSE

Pretreatment:

Verify pregnancy status. Pretesting and baseline studies indicated; see Monitor.

Premedication:

Premedicate with an antihistamine (e.g., diphenhydramine) and acetaminophen before each infusion.

Denileukin diftitox:

9 or 18 mcg/kg/day administered as an IV infusion for 5 consecutive days. Repeat course every 21 days for 8 cycles.

DOSE ADJUSTMENTS

In patients with hypoalbuminemia, administration of denileukin diftitox should be delayed until serum albumin levels are at least 3 Gm/dL; see Monitor.

DILUTION

Each 2-mL vial contains 300 mcg (150 mcg/mL) of frozen recombinant denileukin diftitox. Thaw in refrigerator (2° to 8° C [36° to 46° F]) for not more than 24 hours or at CRT for 1 to 2 hours. Bring to CRT before preparing dose. Do not heat. Gently swirl contents of vial. Do not shake. Solution may be hazy initially. Haze should clear as solution reaches RT. The concentration of denileukin diftitox must be at least 15 mcg/mL during all steps in the preparation of the infusion solution. This is best accomplished by aseptically withdrawing the calculated dose of denileukin diftitox and injecting it into an empty infusion bag. For each 1 mL of denileukin diftitox from the vial(s), no more than 9 mL of sterile NS without preservative should then be added to the bag. For example: A 70-kg patient receiving a 9-mcg/kg dose would require 630 mcg of denileukin diftitox (or 4.2 mL). Withdraw 4.2 mL of denileukin diftitox from vials and inject into an empty infusion bag. Add no more than 37.8 mL (9 × 4.2 mL) of preservative-free NS to infusion bag. The final solution will be 630 mcg in 42 mL of solution, which equals the desired concentration of 15 mcg/mL. Diluted denileukin diftitox must be prepared and stored in a plastic syringe or soft plastic IV infusion bag. Do not use a glass container; see Compatibility.

Filters:

Manufacturer states, “Do not administer through an in-line filter.”

Storage:

Store unopened vials in freezer at or below −10° C (14° F). Prepared solutions should be administered within 6 hours. Discard unused solution. Do not refreeze.

COMPATIBILITY

Manufacturer states, “Do not physically mix denileukin diftitox with other drugs.” Do not mix in glass. Adsorption to glass may occur in the dilute state.

RATE OF ADMINISTRATION

A single dose evenly distributed over 30 to 60 minutes. Administer via peripheral or central vein by a pump device or IV infusion bag. Do not administer as a bolus injection. Do not administer through an in-line filter. If adverse reactions occur during the infusion, the infusion should be discontinued or the rate should be reduced depending on the severity of the reaction. There is no clinical experience with infusion times lasting more than 80 minutes.

ACTIONS

A recombinant DNA–derived cytotoxic protein. A fusion protein that utilizes both the cytotoxic action of diphtheria toxin and the cell-targeting ability of human interleukin-2 (IL-2) to kill certain leukemia and lymphoma cells. Targets specific receptors (IL-2 receptors) on malignant cells while minimizing damage to normal cells that do not express the receptor. Ex vivo studies suggest that denileukin diftitox interacts with the high-affinity IL-2 receptor on the cell surface and inhibits cellular protein synthesis, resulting in cell death within hours. No differences in pharmacologic action noted based on age, gender, and/or race. Half-life in lymphoma patients is 70 to 80 minutes.

Development of antibodies to denileukin diftitox has been shown to increase clearance; see Precautions.

INDICATIONS AND USES

Treatment of patients with persistent or recurrent cutaneous T-cell lymphoma (CTCL) whose malignant cells express the CD25 component of the IL-2 receptor. The safety and efficacy of denileukin diftitox in patients with CTCL whose malignant cells do not express the CD25 component of the IL-2 receptor have not been examined.

CONTRAINDICATIONS

Hypersensitivity to denileukin diftitox, any of its components, diphtheria toxin, or interleukin-2.

PRECAUTIONS

Administered under the supervision of a physician experienced in the use of antineoplastic therapy and the management of patients with cancer. ■ Administer in a facility equipped and staffed for cardiopulmonary resuscitation and in which the patient can be properly monitored. ■ Infusion and/or hypersensitivity reactions, defined as symptoms occurring within 24 hours of infusion and resolving within 48 hours of the last infusion in that course, have been reported and may be serious or life threatening. Deaths have occurred. Incidence of infusion reactions appears to decrease after the first 2 courses of therapy. ■ Capillary leak syndrome (CLS) has resulted in death. CLS characterized by at least two of the following three symptoms (edema, hypoalbuminemia [3 Gm/dL or less], hypotension) has been reported. Symptoms are not required to occur simultaneously to be described as capillary leak syndrome. Onset can occur at any time. Usually occurs within 2 weeks of the infusion but may be delayed. Patients with edema or pre-existing low serum albumin levels may be predisposed to this syndrome. Symptoms may persist or worsen after denileukin diftitox is discontinued; treatment and/or hospitalization may be required; deaths have been reported. Use special caution in patients with pre-existing cardiovascular disease. ■ A significant percentage of patients treated with denileukin diftitox tested positive for antibodies at baseline, probably due to a prior exposure to diphtheria toxin or its vaccine. With each subsequent course, the percent of patients who tested positive increased, C_{max} and AUC decreased, and clearance increased with increasing antibody formation. The formation of neutralizing antibodies was assessed in a number of patients. Evidence of inhibited functional activity in the cellular assay was seen. ■ Loss of visual acuity (usually with loss of color vision, with or without retinal pigment mottling) has been reported. Some patients recover; however, most report persistent visual impairment.

Monitor:

Before administration of denileukin diftitox, the patient's malignant cells should be tested for CD25 expression. A testing service for the assay of CD25 on skin biopsy samples is available; see manufacturer's prescribing information. ■ Consider baseline and periodic monitoring of CBC and a blood chemistry panel, including liver and renal function, before therapy and weekly during therapy. ■ Monitor serum albumin levels before each course of therapy. Nadir occurs 1 to 2 weeks after administration. Delay administration if necessary until serum albumin levels are at least 3 Gm/dL. Note Dose Adjustments. ■ Observe for capillary leak syndrome. Monitor weight, edema, BP, and serum albumin levels before and during treatment with denileukin diftitox. ■ Monitor for signs and symptoms of infection. Patients with CTCL have a predisposition to cutaneous infections, and binding of denileukin diftitox to activated lymphocytes and macrophages may lead to cell death and may impair patient's immune system. ■ Monitor for thrombocytopenia (platelet count less than 50,000/mm^3). Initiate precautions to prevent excessive bleeding (e.g., inspect IV sites, skin, and mucous membranes; use extreme care during invasive procedures; test urine, emesis, stool, and secretions for occult blood). ■ Monitor injection site. To minimize occurrence or phlebitis, change the injection site frequently. ■ See Precautions, Side Effects, and Antidote.

Patient Education:

Effective contraception required during treatment with denileukin diftitox and for 7 days after the last dose. ■ Promptly report orthostatic hypotension (dizziness), weight gain, or edema following infusion. ■ Weigh self daily. ■ Report breathing problems, chest pain, chills, fever, tachycardia, and/or urticaria following infusion. ■ Report vision changes. ■ Keep physician informed of all side effects.

Maternal/Child:

Based on its mechanism of action, denileukin diftitox may cause fetal harm. These are no available data on use in pregnant women. ■ Discontinue breast-feeding during treatment and for 7 days after the final dose. ■ Safety and effectiveness in pediatric patients not established.

Elderly:

Numbers in clinical studies insufficient to determine whether the elderly respond differently than do younger adults.

DRUG/LAB INTERACTIONS

Drug interaction studies have not been conducted.

SIDE EFFECTS

All patients experienced at least one adverse event. The occurrence of side effects tended to diminish in frequency and severity after the first two courses of therapy. ■ The most common side effects were cough, diarrhea, dyspnea, edema, fatigue, fever, headache, nausea, peripheral edema, pruritus, and rigors. The most common serious side effects were capillary leak syndrome, infusion reactions, and vision changes, including loss of visual acuity. During initial studies the most common reasons for discontinuation of therapy were systemic flu-like symptoms (e.g., anorexia, asthenia, chills, fever, malaise, nausea, and vomiting), hypoalbuminemia, infection, rash, respiratory events (e.g., dyspnea, apnea, pulmonary edema, or pneumonia), and capillary leak syndrome. The most common reasons for therapy-related hospitalization were evaluation of fever, management of capillary leak syndrome, or dehydration secondary to gastrointestinal toxicity. ■ Other reported side effects include anorexia, arthralgia, asthenia, back pain, chest pain, dizziness, dysgeusia, hypotension, myalgia, pain, rash, upper respiratory tract infection, and vomiting.

Post-Marketing:

Hyperthyroidism, hypothyroidism, thyroiditis, thyrotoxicosis, visual acuity loss.

ANTIDOTE

Notify physician of any side effects. If adverse reactions occur during administration, the infusion should be discontinued or the rate should be reduced depending on the severity of the reaction. If a serious infusion reaction occurs, immediately stop and permanently discontinue denileukin diftitox. IV antihistamines, corticosteroids, and/or epinephrine may be required. Most symptoms of the flu-like syndrome will respond to treatment with antipyretics and/or antiemetics (e.g., promethazine [Phenergan] or prochlorperazine [Compazine]). Premedication with acetaminophen and an antihistamine 30 to 60 minutes before each infusion may help reduce the frequency and/or severity of symptoms. While on therapy, patients may continue to receive acetaminophen every 4 to 6 hours while awake. Fever, chills, and/or pain not controlled with acetaminophen alone may be treated with an NSAID. Rigors may be treated with meperidine. Skin rashes may require treatment with topical and/or oral corticosteroids. Treatment of capillary leak syndrome depends on whether edema or hypotension is the primary clinical problem. Patients who present with dehydration should be considered for IV fluid replacement therapy. If BP is still not adequate after replacement therapy, pressor agents (e.g., dopamine) should be considered. Use of diuretics should be avoided in patients whose intravascular depletion has not been corrected. However, patients who present primarily with edema may benefit from diuretic therapy. Continuous monitoring of fluid status, weight, and BP is essential. If overdose occurs, hepatic and renal function and overall fluid status should be closely monitored. Resuscitate as necessary.

DESMOPRESSIN ACETATE

(des-moh-**PRESS**-in **AS**-ah-tayt)
DDAVP, 1-Deamino-8-D-Arginine Vasopressin
Hormone
Antidiuretic
Antihemorrhagic
pH 3.5 to 4

USUAL DOSE

Preassessment required based on diagnosis; see Monitor.

Diabetes insipidus:

2 to 4 mcg daily in 2 divided doses. Adjust each dose individually for an adequate

diurnal rhythm of water turnover. IV dose has 10 times the antidiuretic effect of intranasal desmopressin.

Hemophilia A and von Willebrand's disease (Type 1):

0.3 mcg/kg of body weight. If used preoperatively, administer 30 minutes before the scheduled procedure. The necessity for repeat administration of desmopressin or the use of any blood products for hemostasis should be determined by laboratory response and the clinical condition of the patient; see Monitor.

DOSE ADJUSTMENTS

Many specific requirements depending on diagnosis; see Limitations of Use, Precautions, and Monitor. ■ Dosing should be cautious in the elderly. Consider potential for decreased organ function and concomitant disease or drug therapy. See Elderly and Contraindications. ■ Reduce dose accordingly (to ¹⁄₁₀ of the intranasal dose) when transferring from intranasal to IV administration.

DILUTION

Diabetes insipidus:

May be given undiluted.

Hemophilia A and von Willebrand's disease (Type 1):

Dilute a single dose in 10 mL of NS for pediatric patients under 10 kg; 50 mL for adults and pediatric patients over 10 kg. Must be given as an infusion.

Storage:

Refrigerate at 2° to 8° C (36° to 46° F). Use diluted product promptly.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Diabetes insipidus:

A single dose by IV injection over 1 minute.

Hemophilia A and von Willebrand's disease (Type 1):

A single dose as an infusion over 15 to 30 minutes.

ACTIONS

A synthetic analog of the natural hormone arginine vasopressin, an antidiuretic hormone affecting renal water conservation (human antidiuretic hormone—ADH). Has been shown to be more potent than arginine vasopressin in increasing plasma levels of factor VIII activity in patients with hemophilia A and von Willebrand's disease (Type 1).

Produces dose-related increase in factor VIII levels within 30 minutes and peaks in 90 to 120 minutes. Onset of action as an antidiuretic is prompt. When administered by IV injection, desmopressin has an antidiuretic effect about 10 times that of an equivalent dose administered intranasally. Half-life is biphasic (7.8 minutes for fast phase and 75.5 minutes for slow phase). Increases water resorption in the kidney, increases urine osmolality, and decreases urine output. Increases plasma levels of von Willebrand factor, factor VIII, and t-PA, thereby contributing to a shortened activated partial thromboplastin time (aPTT) and bleeding time. Clinically effective antidiuretic doses are usually below the threshold levels for effects on vascular or visceral smooth muscle. Excreted in urine.

INDICATIONS AND USES

Diabetes insipidus:

Antidiuretic replacement therapy in the management of central (cranial) diabetes insipidus and for the management of temporary polyuria and polydipsia following head trauma or surgery in the pituitary region.

Hemophilia A and von Willebrand's disease (Type 1):

Indicated in patients with hemophilia A and in patients with mild to moderate classic von Willebrand's disease (Type I) who have factor VIII coagulant activity levels greater than 5%. In both indications, desmopressin will often maintain hemostasis during surgical procedures and postoperatively when administered 30 minutes before a scheduled procedure and will also stop bleeding in episodes of spontaneous or trauma-induced injuries such as hemarthroses, intramuscular hematomas, or mucosal bleeding.

Limitations of use:

Ineffective for the treatment of nephrogenic diabetes insipidus. ■ Not indicated for the treatment of hemophilia A or von Willebrand's disease (Type I) with factor VIII coagulant activity levels equal to or less than 5%; see Monitor. ■ Not indicated for the treatment of hemophilia B. ■ Not indicated in patients who have factor VIII antibodies. ■ Not indicated for the treatment of severe classic von Willebrand's disease (Type I) and when there is evidence of an abnormal molecular form of factor VIII antigen.

CONTRAINDICATIONS

Infants under 3 months of age with hemophilia A or von Willebrand's disease, known hypersensitivity to desmopressin or any of the components of DDAVP injection, patients with moderate to severe renal impairment (CrCl less than 50 mL/min), and patients with hyponatremia or a history of hyponatremia.

PRECAUTIONS

A potent antidiuretic. Administration may lead to water intoxication and/or hyponatremia, which can be fatal. Fluid restriction is recommended. ■ When administered to patients who do not have a need for the antidiuretic effect, fluid intake should be adjusted downward to decrease the potential occurrence of water intoxication and hyponatremia. Pediatric and elderly patients may be at increased risk. ■ Should not be used to treat Type IIB von Willebrand's disease; platelet aggregation may be induced. ■ Use with caution in patients with habitual or psychogenic polydipsia. May be more likely to drink excessive amounts of water, increasing their risk of hyponatremia. ■ Use caution in patients with coronary artery insufficiency or hypertensive cardiovascular disease; has infrequently produced hypertension or hypotension, with a reflex increase in heart rate. ■ Use with caution in patients predisposed to thrombus formation. There have been rare reports of thrombotic events following administration of desmopressin. ■ Patients with conditions associated with fluid and electrolyte imbalance (e.g., cystic fibrosis, CHF, renal disorders) are prone to hyponatremia; use with caution. ■ Severe hypersensitivity reactions, including anaphylaxis, have been reported. ■ See Drug Interactions.

Monitor:

All diagnoses:

Monitor BP and pulse during infusion. ■ Monitor fluid intake and urine volume. Monitor for S/S of hyponatremia, especially in high-risk patient populations (pediatric patients, the elderly, and patients with CHF). S/S may include headache, nausea and vomiting, decreased serum sodium, weight gain, restlessness, fatigue, lethargy, disorientation, depressed reflexes, loss of appetite, irritability, muscle weakness, muscle spasms, and abnormal mental status (e.g., confusion, decreased consciousness, hallucinations). Severe symptoms may include seizure, coma, and respiratory arrest caused by an extreme decrease in plasma osmolality.

Diabetes insipidus:

Confirm diagnosis of diabetes insipidus with urinalysis, the water deprivation test, or the hypertonic saline infusion test. ■ Fluid restriction indicated; see Precautions. ■ Monitor continued response by measuring urine output and osmolality. Monitoring of plasma osmolality may be indicated. ■ Monitor urine specific gravity and serum electrolytes. ■ Monitor continued response by measuring urine output and osmolality. ■ Monitoring of plasma osmolality may be indicated. ■ Accuracy and effectiveness of dose measured by duration of sleep and adequate, not excessive, water turnover.

Hemophilia A:

Determine factor VIII coagulant activity before administration for hemostasis. ■ Monitor factor VIII coagulant activity, factor VIII antigen, factor VIII ristocetin cofactor (von Willebrand factor), and aPTT to assess patient status during treatment. ■ Do not rely on desmopressin, but it may be considered for use in patients with factor VIII activity levels from 2% to 5% with careful monitoring. Generally used only when the factor VIII activity level is above 5%.

von Willebrand's disease (Type 1):

Most effective when factor VIII activity level above 5%. ■ Monitor bleeding time, factor VIII coagulant activity, factor VIII ristocetin cofactor activity, and factor VIII von

Willebrand factor antigen during therapy to assess patient status. Patients with severe homozygous von Willebrand's disease with factor VIII coagulant activity and factor VIII von Willebrand factor antigen levels less than 1% are least likely to respond to treatment with desmopressin.

Hemophilia and von Willebrand's disease:

Determine need for repeat administration of desmopressin or use of blood products by laboratory response as well as the clinical condition of the patient. Tachyphylaxis (lessening of response; i.e., a gradual diminution of the factor VIII activity increase) has been seen when given more frequently than every 48 hours.

Patient Education:

Careful monitoring of fluid intake indicated in patients with diabetes insipidus. ■ When antidiuretic effect is not needed, caution patients (especially the young and the elderly) to limit fluid intake to satisfy thirst needs only; this decreases potential occurrence of water intoxication and hyponatremia.

Maternal/Child:

Category B: use only when clearly indicated in pregnancy and breast-feeding. ■ Risk of hyponatremia and water intoxication increased in pediatric patients. Restrict fluid intake. ■ Safety for use in pediatric patients under 12 years of age with diabetes insipidus not established. ■ See Contraindications.

Elderly:

Risk of hyponatremia and water intoxication increased. Use caution and restrict fluid intake. ■ Response similar to that seen in younger adults. Dosing should be cautious in the elderly. Monitor renal function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Has been used with aminocaproic acid without adverse effects. ■ May produce hypertension with other **vasopressors** (e.g., dopamine). ■ Use caution when administered concurrently with other medications that can increase the risk of water intoxication with hyponatremia (e.g., **carbamazepine, chlorpromazine, lamotrigine, NSAIDs, opiate analgesics, selective serotonin reuptake inhibitors, tricyclic antidepressants**).

SIDE EFFECTS

Mild abdominal cramps, nausea, transient headache, and vulval pain are most common and may disappear with reduced doses. Facial flushing, hypertension (slight), and/or hypotension with a compensatory tachycardia have occurred. May cause burning, local erythema, and swelling at site of injection. Most serious side effects include hyponatremia with resultant sequelae (see Precautions), water intoxication, and thrombotic events (cerebrovascular thrombosis, MI). Anaphylaxis has been reported.

Overdose:

Confusion, continuing headache, drowsiness, problems passing urine, rapid weight gain due to fluid retention.

Post-Marketing:

Hyponatremia (can be fatal), hyponatremic convulsions associated with concomitant use of oxybutynin (Ditropan) and imipramine (Tofranil-PM), thrombotic events (e.g., acute MI, acute cerebrovascular thrombosis).

ANTIDOTE

Notify physician of all side effects. Most will respond to reduction of dose or rate of administration, or symptomatic treatment. May need to discontinue drug. If overdose occurs, treat by reducing dose or frequency of administration, or discontinue drug if indicated. There is no known specific antidote for desmopressin acetate. Treat hypersensitivity with oxygen, epinephrine, antihistamines (e.g., diphenhydramine), vasopressors, corticosteroids, albuterol, IV fluids, and ventilation equipment as indicated. Resuscitate as necessary.

DEXAMETHASONE SODIUM PHOSPHATE

(dex-ah-**METH**-ah-zohn **SO**-dee-um **FOS**-fayt)
Decadron, Decadron Phosphate
Hormone (corticosteroid)
Anti-inflammatory Antiemetic
Immunosuppressant Diagnostic agent (oral)
pH 7 to 8.5

USUAL DOSE

The **usual initial dose** may vary from 0.5 to 9 mg/day depending on patient condition and response. Dosage must be individualized. IV dexamethasone is usually given in an emergency situation or when oral dosing is not feasible, and the parenteral dosage ranges are usually one-third to one-half the oral doses given every 12 hours. However, administration of dosages exceeding the usual dosages may be justified in certain overwhelming, acute, life-threatening situations. Repeat until adequate response, then decrease dose as indicated using the lowest dose that will maintain an adequate clinical response.

Anti-inflammatory:

See average dose range above. Some sources recommend administering total daily dose divided every 6 to 12 hours.

Unresponsive shock:

Several regimens have been suggested:

1 to 6 mg/kg as a single injection; *or*
40 mg. Repeat every 2 to 6 hours as needed; *or*
20 mg as a ***loading dose,*** followed by a continuous infusion of 3 mg/kg equally

distributed over 24 hours. High-dose treatment is used until patient condition stabilizes, usually no longer than 48 to 72 hours.

Cerebral edema:

Loading dose: 10 mg. ***Maintenance dose:*** 4 mg every 6 hours until maximum response has been noted (usually given IM). May be continued for several days postoperatively in patients requiring brain surgery. Switch to oral dexamethasone (1 to 3 mg three times daily) as soon as possible and taper over 5 to 7 days. Nonoperative cases may require continuous therapy to remain free of symptoms of increased intracranial pressure.

Cerebral edema in recurrent or inoperable brain tumors:

2 mg every 8 to 12 hours (usually given IM) to relieve symptoms of increased intracranial pressure. Adjust based on patient response.

Antiemetic in management of chemotherapy-associated nausea and vomiting (prevention):

Several regimens are in use. Optimum dose has not been established.

Usual dose is 8 to 20 mg before chemotherapy. Lower doses (IV or PO) may be given over the next 24 to 72 hours if necessary. May be used alone or in combination with aprepitant or fosaprepitant and a 5-HT_3 antagonist (e.g., ondansetron) depending on emetogenic potential of chemotherapeutic agents.

Airway edema:

Adult and pediatric patients:

0.5 to 2 mg/kg/24 hr in equally divided doses every 6 hours (0.125 to 0.5 mg/kg every 6 hours) beginning 24 hours before elective extubation. Continue for 4 to 6 doses after extubation.

Allergic conditions:

(Usually given IM or PO) 4 to 8 mg on the first day, then PO in decreasing doses (1.5 mg every 12 hours on Days 2 and 3; 0.75 mg every 12 hours on Day 4; and 0.75 mg on Days 5 and 6).

Meningitis:

Adult and pediatric patients:

0.15 mg/kg/dose every 6 hours for 2 to 4 days. Administer 10 to 20 minutes before or concurrently with the first dose of antibiotic.

Primary or secondary adrenocortical insufficiency (physiologic replacement):

0.03 to 0.15 mg/kg/24 hr or 0.6 to 0.75 $mg/M^2/24$ hr given in divided doses every 6 to 12 hours (0.015 to 0.075 mg/kg every 12 hours, or 0.0075 to 0.0375 mg/kg every 6 hours, or 0.3 to 0.375 mg/M^2 every 12 hours, or 0.15 to 0.1875 mg/M^2 every 6 hours).

Usually given IM. Dexamethasone has minimal mineralocorticoid properties; may require a concomitant mineralocorticoid (e.g., fludrocortisone). Hydrocortisone is the drug of choice for this indication.

PEDIATRIC DOSE

See Maternal/Child. Dose should be based on the severity of the disease and the patient response rather than on strict adherence to a dose indicated by age, weight, or body surface area.

Cerebral edema:

Use smallest effective dose (oral route preferred). Manufacturer recommends 0.2 mg/kg/24 hr in divided doses. An alternate source recommends: ***Loading dose:*** 1 to 2 mg/kg of body weight for 1 dose. ***Maintenance dose:*** 1 to 1.5 mg/kg/24 hr in equally divided doses every 4 to 6 hours (0.17 to 0.25 mg/kg every 4 hours or 0.25 to 0.375 mg/kg every 6 hours) for 5 days, then gradually decrease. Maximum dose is 16 mg/24 hr.

Airway edema:

See Usual Dose.

Croup:

0.6 mg/kg/dose × 1 dose.

Antiemetic in management of chemotherapy-associated nausea and vomiting (prevention):

Several regimens are in use. Optimum dose has not been established. Doses may range from 5 to 10 mg/M^2/dose. May be used alone or in combination with other antiemetics depending on emetogenic potential of chemotherapeutic agents.

Anti-inflammatory:

0.08 to 0.3 mg/kg/24 hr in equally divided doses every 6 to 12 hours (0.04 to 0.15 mg/kg every 12 hours or 0.02 to 0.075 mg/kg every 6 hours).

Meningitis:

See Usual Dose.

DOSE ADJUSTMENTS

Use lowest possible dose required to control condition being treated. When dose reduction is possible, decrease dose gradually while monitoring for S/S of disease exacerbation. ■ Because complications of treatment with glucocorticoids depend on dose and duration of therapy, a risk/benefit decision must be made for each patient regarding dose and duration of treatment and whether daily or intermittent therapy should be used. ■ Clearance of corticosteroids is decreased in patients with hypothyroidism and increased in patients with hyperthyroidism. Dose adjustment may be required. ■ See Drug/Lab Interactions.

DILUTION

May be given undiluted or added to IV dextrose or saline solutions and given as an infusion.

Storage:

Store at CRT. Avoid freezing. Protect from light. Use diluted solutions within 24 hours. Sensitive to heat; do not autoclave. Protect from freezing.

COMPATIBILITY

Compatibility information not available from manufacturer. Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

A single dose over at least 1 minute. Rapid administration may be associated with perineal burning or tingling. As an IV infusion, give at prescribed rate.

ACTIONS

An anti-inflammatory glucocorticoid. A synthetic adrenocortical steroid with minimal mineralocorticoid properties. Causes minimal sodium retention. Glucocorticoids cause profound and varied metabolic effects. They are primarily used for their potent anti-inflammatory effects on different organ systems and their ability to modify the body's immune response. The mechanism of antiemetic activity of dexamethasone has not been established. Approximately seven times as potent as prednisolone and 27 times as potent as hydrocortisone. Onset of action is prompt. Metabolized primarily in the liver and excreted as inactive metabolites in urine. Crosses the placental barrier. Excreted in breast milk.

INDICATIONS AND USES

May be used primarily as an anti-inflammatory or immunosuppressive agent for the treatment of various diseases, including endocrine, rheumatic, collagen, dermatologic, ophthalmic, gastrointestinal, respiratory, hematologic, and neoplastic diseases or disorders (see manufacturer's prescribing information). ■ Supplementary therapy for severe allergic/hypersensitivity reactions. ■ Reduction of acute edematous states (cerebral edema, airway edema). ■ Shock unresponsive to conventional therapy. ■ Acute exacerbations of disease for patients receiving steroid therapy. ■ Adrenocortical insufficiency; total, relative, and operative. ■ Has numerous other uses by other routes of administration (e.g., IM, intra-articular, intralesional, intrasynovial, soft-tissue injection, oral inhalant).

Unlabeled uses:

Antiemetic for chemotherapy-induced nausea and vomiting (prevention). ■ Adjunct to treatment of meningitis with antibiotics (to reduce incidence of ototoxicity). ■ Dexamethasone or betamethasone is given IM to the mother to accelerate the production of lung surfactant in utero in the prevention of respiratory distress syndrome of premature infants.

CONTRAINDICATIONS

Systemic fungal infections. Another source lists hypersensitivity to any product component, including sulfites, and cerebral malaria.

PRECAUTIONS

Corticosteroids can produce reversible hypothalamic-pituitary-adrenal (HPA) axis suppression with the potential for glucocorticosteroid insufficiency after withdrawal of treatment. Adrenocortical insufficiency may result from too-rapid withdrawal of corticosteroids and may be minimized by gradual reduction of dosage. This type of relative insufficiency may persist for months after discontinuation of therapy; therefore hormone therapy should be reinstituted in any situation of stress occurring during that period (e.g., surgery, trauma, infection). If the patient is already receiving steroids, the dosage may need to be increased. Because mineralocorticoid secretion may be impaired, salt and/or a mineralocorticoid should be administered concurrently. ■ Prolonged use of corticosteroids may increase susceptibility to infection, reactivate latent infectious diseases, or mask signs of infection. ■ Pediatric patients who are on immunosuppressant corticosteroids are more susceptible to infection than healthy children. Infections such as chickenpox and measles can have a more serious or even fatal course. Adults and pediatric patients who have not had these diseases should take care to avoid exposure. If exposed, therapy with varicella zoster immune globulin (VZIG) or IVIG may be indicated. If chickenpox develops, treatment with antiviral agents should be considered. ■ Corticosteroids should be used with great caution in patients with known or suspected *Strongyloides* (threadworm) infestation. Corticosteroid-induced immunosuppression may lead to *Strongyloides* hyperinfection and dissemination with widespread larval migration, often accompanied by severe enterocolitis and potentially fatal gram-negative sepsis. ■ The use of dexamethasone in patients with active tuberculosis should be restricted to cases of fulminating or disseminated tuberculosis in which the corticosteroid is being used for management of disease in conjunction with an appropriate antituberculosis regimen. ■ If corticosteroids are indicated in patients with latent tuberculosis or tuberculin reactivity, reactivation of the disease may occur. Chemoprophylaxis is indicated during prolonged corticosteroid therapy. ■ Prolonged use of corticosteroids may produce posterior subcapsular cataracts or glaucoma with possible damage to the optic nerves and may enhance the establishment of secondary ocular infections due to fungi or viruses. ■ Use with caution in patients with ocular herpes simplex; corneal perforation can occur. ■ Use with caution in hypothyroidism and cirrhosis; effect of corticosteroids may be enhanced. ■ Hypertension, sodium and water retention, and potassium and calcium excretion can occur with large doses of dexamethasone. Dietary sodium restriction and potassium supplementation may be necessary. Caution and close monitoring is required in patients with existing cardiovascular disease. ■ Use with caution in patients with nonspecific ulcerative colitis (if there is a probability of impending perforation, abscess, or other pyogenic infection), diverticulitis, fresh intestinal anastomoses, active or latent peptic ulcer disease, renal insufficiency, hypertension, osteoporosis, and myasthenia gravis. ■ Psychic derangements (e.g., euphoria, insomnia, mood swings, personality changes, severe depression, frank psychotic manifestations) can occur in patients receiving corticosteroids. Pre-existing emotional instability or psychotic tendencies may be aggravated. ■ Rare instances of anaphylactoid reactions have been reported. ■ Use with caution in patients who have had a recent MI. Ventricular free wall rupture has been reported. ■ Use with caution in patients at risk for osteoporosis. Corticosteroids decrease bone formation, increase bone resorption, and decrease the protein matrix of the bone. May lead to inhibition of bone growth in pediatric patients and the development of osteoporosis at any age. ■ An acute myopathy has been reported with the use of high doses of corticosteroids. Most often seen in patients with disorders of neuromuscular transmission (e.g., myasthenia gravis) or in patients receiving concomitant therapy with neuromuscular blocking drugs. Myopathy is generalized, may involve ocular and respiratory muscles, and may result in quadriparesis. Clinical improvement following discontinuation of corticosteroids may take weeks to years. ■ Kaposi's sarcoma has been reported in patients receiving corticosteroid therapy, most often for chronic conditions. Clinical improvement may occur if therapy is discontinued. ■ Some products may contain sulfites; use caution in patients with allergies.

Monitor:

May increase insulin needs in diabetes; monitor blood glucose. ■ Monitor electrolytes periodically. May cause sodium retention and potassium and calcium excretion. ■ Monitoring of BP may be indicated; may cause hypertension secondary to fluid and electrolyte disturbances. ■ Monitor for S/S of infection; S/S may be masked. ■ Patients with latent tuberculosis should be monitored for reactivation of the disease. ■ Periodic ophthalmic exams may be necessary with prolonged treatment. ■ Monitor for S/S of a hypersensitivity reaction. ■ Elevation of creatine kinase may occur with acute myopathy. Monitor if indicated. ■ See Drug/Lab Interactions.

Patient Education:

Promptly report edema, tarry stools, or weight gain. Promptly report anorexia, diarrhea, dizziness, fatigue, low blood sugar, nausea, weakness, weight loss, and vomiting. May indicate adrenal insufficiency after dose reduction or discontinuing therapy. ■ May mask signs of infection and/or decrease resistance. ■ Patients with diabetes may have an increased requirement for insulin or oral hypoglycemics. ■ Avoid immunization with live virus vaccines. ■ Carry ID stating steroid dependent if receiving prolonged therapy.

Maternal/Child:

Category C: use with caution; benefits must outweigh risks. ■ Discontinue breast-feeding. ■ Observe newborn for hypoadrenalism if mother has received large doses. ■ Monitor growth and development of pediatric patients receiving prolonged treatment. ■ Use of a preservative-free solution recommended for neonates.

Elderly:

Use cautiously in the smallest possible dose. Monitor BP, blood glucose, and electrolytes carefully. ■ Increased risk of hypertension. ■ Higher risk of glucocorticoid-induced osteoporosis.

DRUG/LAB INTERACTIONS

Some sources list additional interactions; review drug profile with pharmacist.

Aminoglutethimide and mitotane suppress adrenal function and increase metabolism of dexamethasone. Not recommended for concurrent use, or dexamethasone dose may need to be increased to be effective. Use of hydrocortisone suggested. ■ Metabolism increased and effects reduced by **hepatic enzyme–inducing agents** (e.g., alcohol, barbiturates [e.g., phenobarbital], hydantoins [e.g., phenytoin], rifampin); dose adjustments may be required when adding or deleting from drug profile. ■ Risk of hypokalemia increased with **amphotericin B or potassium-depleting diuretics** (e.g., thiazides, furosemide, ethacrynic acid). Monitor potassium levels and cardiac function. ■ Increased risk of **digoxin** toxicity secondary to hypokalemia. ■ May also decrease effectiveness of **potassium supplements;** monitor serum potassium. ■ **Diuretics** decrease sodium and fluid retention effects of corticosteroids; corticosteroids decrease sodium excretion and diuretic effects of diuretics. ■ Concurrent use with **NSAIDs** may increase the risk of GI toxicity. ■ Aspirin should be used cautiously in conjunction with corticosteroids in hypoprothrombinemia. ■ Increased activity of both cyclosporine and corticosteroids may occur when used concurrently. Convulsions have been reported with concurrent use. ■ Clearance increased and effects decreased with **ephedrine.** ■ May enhance the adverse/toxic effects of **anticholinesterases** (e.g., neostigmine); increased muscle weakness may occur. ■ May decrease the effectiveness of **isoniazid, salicylates, and somatrem**; dose adjustments may be required. ■ Clearance decreased and effects increased with **estrogens, macrolide antibiotics** (e.g., azithromycin), **oral contraceptives, and ketoconazole**. ■ May interact with **anticoagulants, nondepolarizing muscle relaxants** (e.g., atracurium), **or theophyllines;** may inhibit or potentiate action; monitor carefully. ■ Monitor patients receiving **insulin** carefully; dose adjustments may be required. ■ Do not vaccinate with **live or live-attenuated virus vaccines** (e.g., smallpox) during therapy. Killed or inactivated vaccines may be administered. However, patients on corticosteroid therapy may exhibit a diminished response. ■ Toxic epidermal necrolysis has been reported with concomitant use of thalidomide and corticosteroids; use caution. ■ See Precautions. ■ Decreases uptake of **radioactive material** in cerebral edema; will alter brain scan.

SIDE EFFECTS

Do occur but are usually reversible: burning, itching, and tingling in the anogenital region; Cushing’s syndrome; electrolyte imbalance; euphoria; fluid retention; glycosuria; headache; hyperglycemia; hypersensitivity reactions including anaphylaxis; hypertension; impaired wound healing; insomnia; leukocytosis; menstrual irregularities; mood swings; peptic ulcer; perforation and hemorrhage; protein catabolism; sweating; thromboembolism; tumor lysis syndrome; weakness; and many others.

ANTIDOTE

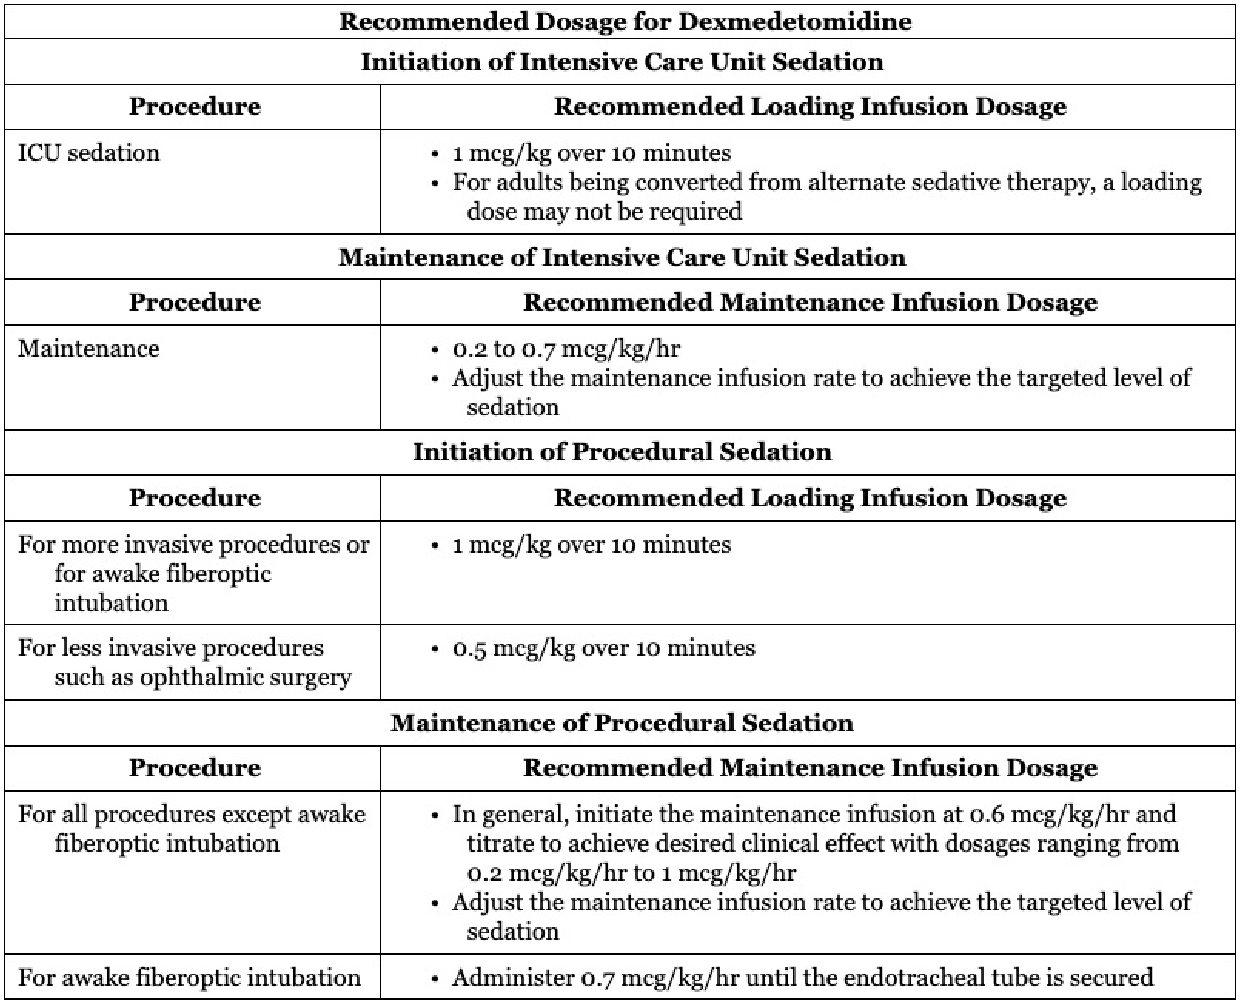
Notify the physician of any side effect. Treat side effects as indicated. Resuscitate as necessary for anaphylaxis and notify physician. Keep epinephrine immediately available.

DEXMEDETOMIDINE HYDROCHLORIDE

(dex-**med**-ih-**TOM**-ih-deen hy-droh-**KLOR**-eyed)
Precedex
Alpha$_2$-adrenoceptor agonist
Sedative-hypnotic
pH 4.5 to 7

USUAL DOSE

Dosing should be individualized and titrated to desired sedation. Recommended loading and maintenance doses for various procedures are outlined in the following chart. See Dose Adjustments.



Recommended Dosage for Dexmedetomidine	
Initiation of Intensive Care Unit Sedation	
Procedure	**Recommended Loading Infusion Dosage**
ICU sedation	• 1 mcg/kg over 10 minutes • For adults being converted from alternate sedative therapy, a loading dose may not be required
Maintenance of Intensive Care Unit Sedation	
Procedure	**Recommended Maintenance Infusion Dosage**
Maintenance	• 0.2 to 0.7 mcg/kg/hr • Adjust the maintenance infusion rate to achieve the targeted level of sedation
Initiation of Procedural Sedation	
Procedure	**Recommended Loading Infusion Dosage**
For more invasive procedures or for awake fiberoptic intubation	• 1 mcg/kg over 10 minutes
For less invasive procedures such as ophthalmic surgery	• 0.5 mcg/kg over 10 minutes
Maintenance of Procedural Sedation	
Procedure	**Recommended Maintenance Infusion Dosage**
For all procedures except awake fiberoptic intubation	• In general, initiate the maintenance infusion at 0.6 mcg/kg/hr and titrate to achieve desired clinical effect with dosages ranging from 0.2 mcg/kg/hr to 1 mcg/kg/hr • Adjust the maintenance infusion rate to achieve the targeted level of sedation
For awake fiberoptic intubation	• Administer 0.7 mcg/kg/hr until the endotracheal tube is secured

DOSE ADJUSTMENTS

Consider reduced doses in patients with hepatic impairment. ■ For patients over 65 years of age receiving ICU sedation, a dose reduction may be considered. ■ For patients over 65 years of age receiving procedural sedation, the recommended loading infusion dosage of dexmedetomidine is 0.5 mcg/kg over 10 minutes. Consider dosage reduction for maintenance of procedural sedation in the elderly. ■ Dose reduction of either or both agents may be required when coadministered with anesthetics, sedatives, hypnotics, or opioids; see Drug/Lab Interactions. ■ No dose adjustment indicated based on gender or renal function.

DILUTION

Supplied in single-use vials containing 200 mcg/2 mL. Also available in 400 mcg/4 mL or 1000 mcg/10 mL multidose vials. Vials must be diluted before administration. Preparation of the solution is the same whether for loading dose or maintenance infusion. Withdraw 2 mL of dexmedetomidine and add to 48 mL of NS (or add 4 mL of dexmedetomidine to 96 mL of NS) for a final concentration of 4 mcg/mL. Shake gently. Also available in premixed, ready-to-use, single-use containers containing 80 mcg/20 mL, 200 mcg/50 mL, or 400 mcg/100 mL of dexmedetomidine in NS. No further dilution is required.

Storage:

Store unopened vials and premixed solutions at CRT. Before use, diluted dexmedetomidine solution (compounded product) may be stored for up to 4 hours at RT or up to 24 hours at 2° to 8° C (36° to 46° F).

COMPATIBILITY

According to the manufacturer, the **compatibility** of dexmedetomidine with blood or plasma has not been established; avoid coadministration. Manufacturer lists as **incompatible** with amphotericin B and diazepam (Valium). Absorption of dexmedetomidine to some types of natural rubbers may occur. Although dexmedetomidine is dosed to effect, it is advisable to use administration components that are made with synthetic or coated natural rubber gaskets.

Manufacturer lists the following **compatibilities:** NS, D5W, 20% mannitol, LR, magnesium sulfate (100 mg/mL), and 0.3% potassium chloride solution.

Other sources suggest specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Administer using a controlled infusion device. Rapid IV or bolus administration may result in bradycardia and sinus arrest.

Loading dose:

Infuse over 10 minutes. Increase infusion time (decrease infusion rate) if transient hypertension develops; see Monitor and Antidote.

Maintenance infusion:

See Usual Dose. Titrate to desired clinical effect.

ACTIONS

A central $alpha_2$-adrenergic agonist with sedative properties. In animal studies, the desired $alpha_2$ selectivity is seen following slow IV infusions of low and medium doses (10 to 300 mcg/kg), but both $alpha_1$ and $alpha_2$ activity are seen following slow IV infusion of high doses (equal to or greater than 1,000 mcg/kg) or with rapid IV administration. Appears to have both sedative and moderate analgesic activity and may decrease the requirement for concomitant sedation and analgesia when used as a short-term infusion in the ICU setting. Other actions include reduced BP, HR, and reduced salivation. Highly protein bound. Almost completely metabolized in the liver via direct glucuronidation and cytochrome P_{450}-mediated metabolism. Metabolites excreted primarily in urine and to a small extent in feces. Half-life is approximately 2 hours.

INDICATIONS AND USES

Sedation of initially intubated and mechanically ventilated patients during treatment in an intensive care setting. Should be administered by continuous infusion not to exceed 24 hours. Dexmedetomidine has been infused before, during, and after extubation. It is not necessary to discontinue dexmedetomidine before extubation. ■ Sedation of nonintubated patients before and/or during surgical and other procedures.

CONTRAINDICATIONS

None noted.

PRECAUTIONS

Administered by persons skilled in the management of patients in the intensive care or operating room setting; patient must be intubated. ■ Clinically significant episodes of bradycardia and sinus arrest have been reported in young, healthy volunteers with high vagal tone or after rapid IV or bolus administration of dexmedetomidine; see Rate of Administration. ■ Hypotension, bradycardia, and sinus arrest have been reported. Some of these cases resulted in fatalities. Decreases sympathetic nervous system activity and has the potential to augment bradycardia induced by vagal stimuli. Use caution in patients with advanced heart block, severe ventricular dysfunction, diabetes mellitus, chronic hypertension, hypovolemia, and in the elderly; hypotension and/or bradycardia may be more pronounced. Clinical intervention may be required; see Antidote. ■ Transient hypertension has been observed primarily during the loading dose and is likely due to the initial peripheral vasoconstrictive effects of dexmedetomidine; see Rate of Administration and Antidote. ■ Patients may be arousable and alert when stimulated. This alone should not be considered as evidence of lack of effectiveness in the absence of other clinical signs and symptoms. ■ The dependence potential of dexmedetomidine has not been studied in humans. May produce a clonidine-like withdrawal syndrome if discontinued abruptly. ■ Dexmedetomidine should not be administered for longer than 24 hours. Adverse events related to withdrawal (e.g., agitation, hypertension, nausea and vomiting, tachycardia) have been reported with prolonged infusions. Most withdrawal-related events were seen 24 to 48 hours following discontinuation of the infusion. Withdrawal symptoms have not been seen with discontinuation of short-term infusions (procedural sedation with infusions of less than 6 hours). ■ Use beyond 24 hours has been associated with tolerance and tachyphylaxis and a dose-related increase in adverse reactions. ■ Use with caution in patients with hepatic impairment. Clearance of dexmedetomidine is decreased; see Dose Adjustments.

Monitor:

Continuous monitoring of VS, oxygenation, and cardiac and fluid status imperative. Monitor BP, HR, and oxygen levels during use and as clinically appropriate after discontinuation. ■ Hypovolemia may increase risk of hypotension. ■ Use of a sedation scale (e.g., Ramsay) recommended for monitoring of sedative effect. ■ See Precautions.

Patient Education:

Report abdominal pain, agitation, confusion, constipation, diarrhea, dizziness, excessive sweating, headache, light-headedness, nervousness, salt cravings, weakness, or weight loss that occur within 48 hours.

Maternal/Child:

Safety for use in pregnancy not established. Studies suggest fetal exposure should be expected. ■ Safety for use during labor and delivery and with breast-feeding not established. Use only when clearly indicated. To minimize potential drug exposure to a breast-fed infant, a lactating woman may consider interrupting breast-feeding and pumping and discarding breast milk for 10 hours (approximately 5 half-lives) after receiving dexmedetomidine. ■ Safety and effectiveness in pediatric patients under 18 years of age not established.

Elderly:

In patients older than 65 years, a higher incidence of bradycardia and hypotension was observed following administration of dexmedetomidine. ■ Consider age-related organ impairment and history of previous or concomitant disease or drug therapy. ■ See Dose Adjustments.

DRUG/LAB INTERACTIONS

Potentiated by **anesthetics, sedatives or hypnotics** (e.g., barbiturates, benzodiazepines, propofol), **and opioids** (e.g., morphine). Reduced doses of either drug may be indicated. See Dose Adjustments. ■ Concurrent use with other **vasodilators** (e.g., nitroglycerin, nitroprusside sodium) **or negative chronotropic agents** (e.g., beta blockers, calcium channel blockers) may have an additive hypotensive or bradycardic effect; use with caution.

SIDE EFFECTS

The most common side effects (occurring in more than 2% of patients receiving dexmedetomidine for ICU sedation) included anemia, atrial fibrillation, bradycardia, dry mouth, fever, hypertension, hypotension, and nausea. The most common side effects (occurring in more than 2% of patients receiving dexmedetomidine for procedural sedation) included bradycardia, dry mouth, hypotension, nausea, and respiratory depression. Side effects associated with infusions greater than 24 hours in duration include agitation, ARDS, and respiratory failure. Other reported side effects (for either indication) include abnormal vision, acidosis, acute renal failure, agitation, anxiety, apnea, arrhythmia, atelectasis, bronchospasm, chills, confusion, constipation, delirium, dizziness, dyspnea, hallucination, headache, heart block, hypercapnia, hyperglycemia, hyperkalemia, hypertension, hyperthermia, hypoventilation, hypovolemia, hypoxia, increased alkaline phosphatase, increased GGT (gamma glutamyltransferase), increased ALT, increased AST, increased sweating, infection, light anesthesia, neuralgia, neuritis, oliguria, pain, peripheral edema, pleural effusion, postprocedural hemorrhage, pulmonary edema, rigors, sinus arrest, somnolence, speech disorder, tachycardia, thirst, and vomiting.

Post-Marketing:

Acidosis, cardiac arrest, convulsions, electrocardiogram T-wave inversion and QT prolongation, hyperhidrosis, hypernatremia, hypoglycemia, increased BUN, myocardial infarction, photopsia, polyuria, pruritus, rash, urticaria, and visual impairment.

Overdose:

Bradycardia, cardiac arrest, first-degree AV block, hypotension, second-degree heart block.

ANTIDOTE

Keep physician informed of all side effects. Hypotension and bradycardia may be treated by slowing or stopping the dexmedetomidine infusion, increasing the rate of IV fluid administration, elevation of the lower extremities, or use of pressor amines (e.g., dopamine). Administration of anticholinergic agents (e.g., atropine or glycopyrrolate) may be considered to modify vagal tone. Transient hypertension during loading dose may be treated by decreasing the rate of the infusion. Tachycardia and/or hypertension occurring after discontinuation of prolonged infusions of dexmedetomidine may require supportive therapy. Resuscitate as necessary.

DEXRAZOXANE

(dex-rah-**ZOX**-ayn)
Totect, Zinecard
Antidote
Extravasation antidote
Chemoprotective agent
pH 3.5 to 5.5

USUAL DOSE

Pretreatment:

Verify pregnancy status and baseline studies required; see Monitor.

Totect

Administer once daily for 3 consecutive days. Initiate the first infusion as soon as possible and within 6 hours of extravasation. Doses should be given 24 hours apart (+ or – 3 hours); see Precautions. Recommended regimen is:

Day 1 and Day 2:

1,000 mg/M^2 not to exceed 2,000 mg.

Day 3:

500 mg/M^2 not to exceed 1,000 mg.

Zinecard

Administered in conjunction with doxorubicin. Dose ratio of dexrazoxane to doxorubicin (Adriamycin) is 10:1 (e.g., 500 mg/M^2 dexrazoxane to 50 mg/M^2 doxorubicin). Do not administer doxorubicin before dexrazoxane. Doxorubicin dose must be given within 30 minutes after completion of the dexrazoxane injection.

DOSE ADJUSTMENTS

Totect and Zinecard

Decrease the recommended dose of dexrazoxane by 50% in patients with moderate to severe renal impairment (CrCl less than 40 mL/min). ■ Ratio of Zinecard to doxorubicin will be 5:1 (e.g., 250 mg/M^2 dexrazoxane to 50 mg/M^2 doxorubicin). ■ Consider age-related impaired organ function and concomitant disease or drug therapy in the elderly; see Elderly. ■ See Antidote. ■ Has not been evaluated in hepatic insufficiency.

Zinecard

When administering Zinecard, the dose of dexrazoxane is dependent on the dose of doxorubicin. When the dose of doxorubicin is reduced (e.g., patients with hyperbilirubinemia), adjust the dexrazoxane dose accordingly. Maintain a 10:1 ratio (dexrazoxane to doxorubicin) except in patients with CrCl less than 40 mL/min; see above paragraph.

DILUTION

Specific techniques required;

***see Precautions*.**

Totect

Totect can be prepared with ***either*** SWFI and LR ***or*** 0.167 M sodium lactate injection and NS. More than 1 vial of Totect may be needed to prepare the calculated dose.

Preparation of Totect using SWFI and LR:

Reconstitute each 500-mg vial of lyophilized Totect powder with 50 mL of SWFI (10 mg/mL). Withdraw the calculated dose and further dilute in 1,000 mL of LR. Reconstituted solution must be further diluted within 30 minutes of preparation.

Preparation of Totect using 0.167 M sodium lactate injection and NS:

Reconstitute each 500-mg vial of lyophilized Totect powder with 50 mL of 0.167 M sodium lactate injection solution (10 mg/mL). (To prepare 50 mL of 0.167 M sodium lactate injection solution, add 1.67 mL of 5 mEq/mL sodium lactate injection to 50 mL SWFI.) Withdraw the calculated dose and further dilute in 1,000 mL of NS. Reconstituted solution must be further diluted within 30 minutes of preparation.

Zinecard

Initially reconstitute each 250 mg (500 mg) with 25 mL (50 mL) of SWFI (10 mg/mL). Must be further diluted with LR. Concentration should range from 1.3 to 3 mg/mL. Further dilution of each 250-mg (500-mg) vial with 75 mL (150 mL) of LR would yield 2.5 mg/mL. Fully diluted solution has a pH of 3.5 to 5.5.

Storage: Totect and Zinecard:

Store unopened vials at CRT. ***Totect:*** Store unopened vials in original carton to protect from light. Reconstituted solution should be further diluted within 30 minutes. Diluted product stable for 4 hours from time of reconstitution and dilution when stored below 25° C (77° F) or for up to 12 hours when stored refrigerated between 2° and 8° C (36° and 46° F). ***Zinecard:*** Reconstituted solution stable for 30 minutes at RT or, if necessary, up to 3 hours from the time of reconstitution under refrigeration at 2° to 8° C (36° to 46° F). Fully diluted solutions in LR are stable for 1 hour at RT or up to 4 hours if refrigerated at 2° to 8° C (36° to 46° F). Discard unused solutions.

COMPATIBILITY

Manufacturer states, “Should not be mixed or administered with other drugs”; degrades rapidly at a pH above 7.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Totect

Administer a single dose as an IV infusion equally distributed over 1 to 2 hours. Infuse at RT with normal lighting in a large vein in an extremity/area other than the one affected by the extravasation.

Zinecard

A single dose as an infusion over 15 minutes. Do not administer by IV push. Administer doxorubicin within 30 minutes after completion of Zinecard infusion.

ACTIONS

Dexrazoxane

Distributes throughout total body water. At least partly metabolized. Elimination half-life is 2.1 to 2.5 hours. Primarily excreted in urine. See Drug/Lab Interactions.

Totect

Diminishes tissue damage resulting from extravasation of anthracycline drugs. Exact mode of action unknown. May inhibit topoisomerase II reversibly.

Zinecard

A cardioprotective agent. A potent intracellular chelating agent that readily penetrates cell membranes and interferes with iron-mediated free radical generation thought to be, in part, responsible for anthracycline-induced cardiomyopathy. Reduces the incidence of doxorubicin cardiomyopathy.

INDICATIONS AND USES

Totect

Treatment of extravasation resulting from IV anthracycline chemotherapy.

Zinecard

Reduce the incidence and severity of cardiomyopathy associated with doxorubicin administration in women with metastatic breast cancer who have received a cumulative doxorubicin dose of 300 mg/M^2 and who will continue to receive doxorubicin therapy to maintain tumor control. ■ ***Do not use with the initiation of doxorubicin therapy.***

CONTRAINDICATIONS

Totect

None.

Zinecard

Do not use with chemotherapy regimens that do not contain an anthracycline.

PRECAUTIONS

Totect and Zinecard

Follow guidelines for handling cytotoxic agents. See Appendix A, p. 1308. ■ Usually administered by or under the direction of the physician specialist. ■ For IV infusion only; do not administer IV push. ■ May add to myelosuppression caused by chemotherapeutic agents. Febrile neutropenia has been reported when used with cytotoxic chemotherapy for management of anthracycline extravasation. ■ Use with caution in patients with renal impairment; see Dose Adjustments. ■ Has not been evaluated in hepatic impairment. ■ Hypersensitivity reactions, including anaphylaxis, have been reported. Previous history of allergy to dexrazoxane products should be carefully considered before administration. Consider permanent discontinuation in patients with severe hypersensitivity reactions.

Totect

For IV administration; **not** for local infiltration into extravasation site. Remove cooling procedures such as ice packs, if used, from the extravasation area at least 15 minutes before administration to allow sufficient blood flow to the extravasated area. ■ Use in patients with hepatic impairment is not recommended. Hepatic dysfunction (increases in transaminases and bilirubin) may occur (especially after doses of above 1000 mg/M²).

Zinecard

Evidence indicates that the use of dexrazoxane with the initiation of fluorouracil, doxorubicin, and cyclophosphamide (FAC) therapy interferes with the antitumor efficacy of the regimen. In one breast cancer trial, a lower response rate and a shorter time to progression were seen in patients who received dexrazoxane with their first cycle of FAC therapy. This use is not recommended; see Indications. ■ Secondary malignancies (e.g., acute myeloid leukemia [AML] and myelodysplastic syndrome [MDS]) have been reported in pediatric patients and adults who have received dexrazoxane in combination with chemotherapy (not indicated for use in pediatric patients).

Monitor:

Totect and Zinecard:

Pregnancy testing should be performed before the initiation of chemotherapy; if extravasation occurs, repeat pregnancy testing is not recommended before administration of dexrazoxane because treatment of extravasation of anthracycline chemotherapy should not be delayed. ■ Obtain baseline and periodic renal and liver function tests as indicated. ■ Monitor patients with impaired renal function for signs of hematologic toxicity. ■ Monitor for S/S of hypersensitivity reaction (anaphylaxis, angioedema, bronchospasm, hypotension, loss of consciousness, respiratory distress, and skin reactions). ■ Use of prophylactic antiemetics may be indicated.

Totect:

Monitor CBC and differential and platelet count for increased bone marrow suppression during treatment with dexrazoxane and cytotoxic chemotherapy. ■ Perform local examination for extravasation on a regular basis after treatment and until resolution. ■ If vesicant compounds other than anthracyclines are being used through the same IV access (e.g., vincristine, mitomycin, and vinorelbine), consider treatments for these other vesicant compounds. Totect is not effective against the effects of vesicants other than anthracyclines.

Zinecard:

Obtain baseline CBC and repeat before each course of therapy. Administer Zinecard and chemotherapy only when adequate hematologic parameters are met. ■ Monitor cardiac function before and periodically during therapy to assess left ventricular ejection fraction (LVEF). ■ Reduces but does not eliminate the risk of doxorubicin-induced cardiotoxicity. Monitor for signs of congestive heart failure (e.g., basilar rales, S_3 gallop, paroxysmal nocturnal dyspnea, significant dyspnea on exertion, cardiomegaly by x-ray, or progressive decline from baseline of LVEF).

Patient Education:

Myelosuppression, immunosuppression, and infections may occur. Monitor temperature frequently and report any fevers. Routine blood cell counts required. ■ Promptly report S/S of a hypersensitivity reaction (e.g., dizziness; fainting; hives; swelling of face, lips, tongue, or throat; trouble breathing). ■ Use of effective contraception required in females of reproductive potential during treatment and for 6 months after the last dose of dexrazoxane. Males with female partners of reproductive potential must use effective contraception during treatment and for 3 months after the last dose. Report a suspected pregnancy; see Maternal/Child. ■ May impair fertility in males of reproductive potential. Not known whether these effects on fertility are reversible. ■ Report pain at injection site promptly.

Maternal/Child:

Totect and Zinecard: Avoid pregnancy. Can cause fetal harm. ■ ***Totect:*** Do not breast-feed during treatment and for 2 weeks after final dose. ***Zinecard:*** Discontinue breast-feeding. ***Totect and Zinecard:*** Safety for use in pediatric patients not established.

Elderly:

Response similar to that seen in younger patients. ■ Monitor renal and hepatic function; see Dose Adjustments.

DRUG/LAB INTERACTIONS

Totect and Zinecard

May have additive bone marrow suppressant effects with **other bone marrow suppressants** (e.g., fluorouracil, cyclophosphamide). ■ Does not affect pharmacokinetics of **doxorubicin** or **epirubicin**. ■ Dexrazoxane is not an inhibitor for CYP1A, CYP2C9, CYP2C19, CYP2D6, or CYP3A.

Totect

Dimethylsulfoxide (DMSO) should not be used in patients who are receiving dexrazoxane for treatment of anthracycline-induced extravasation. Efficacy of Totect may be reduced.

Zinecard

Not indicated for use in initiation of doxorubicin therapy; may interfere with antitumor effects of combination regimens.

SIDE EFFECTS

Administered to patients receiving chemotherapeutic agents; side effect profile reflects a combination of dexrazoxane, underlying disease, and chemotherapy. The most common side effects are fever, injection site pain, nausea, postoperative infection, and vomiting. Laboratory abnormalities may include decreased hemoglobin, neutrophils, platelets, WBCs, and sodium and increased AST, ALT, alkaline phosphatase, bilirubin, creatinine, LDH, and total calcium. Alopecia, anorexia, constipation, cough, depression, diarrhea, dizziness, dysphagia, dyspnea, fatigue, headache, infection, insomnia, peripheral edema, stomatitis, and urticaria have been reported.

ANTIDOTE

Keep physician informed of side effects; most will be treated symptomatically. Recovery from myelosuppression similar with or without dexrazoxane. Treat hypersensitivity reactions as needed (e.g., oxygen, antihistamines, epinephrine, corticosteroids, vasopressors, and/or fluids). There is no known antidote for dexrazoxane. Overdose with dexrazoxane can lead to signs of bone marrow failure. Treatment should be symptomatic. Hemodialysis or peritoneal dialysis may be useful.

DEXTRAN 1

(**DEX**-tran)
Promit
Dextran adjunct
Antidote

USUAL DOSE

Availability in the United States is extremely limited.

20 mL (150 mg/mL) 1 to 2 minutes before every IV clinical dextran infusion. If 15 minutes or more elapses before the clinical dextran infusion is started, a full dose of dextran 1 must be repeated before the infusion.

PEDIATRIC DOSE

0.3 mL/kg of body weight. To be given in same manner as adult dose.

DILUTION

May be given undiluted. May be given through Y-tube or three-way stopcock of an infusion set if there is minimum dilution with the primary IV. May not be diluted with or administered through an IV tubing containing clinical dextran infusion.

COMPATIBILITY

According to the manufacturer, dextran 1 should not be diluted or admixed with clinical dextran (high molecular weight or low molecular weight) and should not be given through an IV set used to infuse clinical dextran. Use of a heparin lock is suggested.

RATE OF ADMINISTRATION

IV injection:

A single dose over 1 minute.

ACTIONS

A monovalent hapten, it binds to one of two available sites on dextran-reacting antibodies. An adequate dose (molar excess) given just before the IV administration of clinical dextran solution prevents the formation of immune complexes with the polyvalent clinical dextrans and helps prevent severe anaphylaxis. Incidence of anaphylaxis is 15 to 20 times less. Rapidly excreted in urine.

INDICATIONS AND USES

Prophylaxis of serious anaphylactic reactions associated with IV infusion of clinical dextran solutions.

CONTRAINDICATIONS

Do not give if clinical dextran is contraindicated (severe bleeding disorders; marked hemostatic defects [e.g., thrombocytopenia, hypofibrinogenemia], even if drug-induced [e.g., heparin, warfarin]; breast-feeding and pregnancy unless a life-saving measure; severe congestive cardiac failure; renal failure).

PRECAUTIONS

For IV use only. ■ Will not prevent mild allergic/hypersensitivity reactions induced by clinical dextran solutions. ■ If any reaction occurs to dextran 1, ***do not administer clinical dextran infusion.***

Monitor:

May cause severe hypotension and bradycardia.

Maternal/Child:

Category B: see Contraindications.

DRUG/LAB INTERACTIONS

See Precautions and Dilution.

SIDE EFFECTS

Bradycardia, cutaneous reactions, hypotension (moderate to severe), nausea, pallor, shivering.

ANTIDOTE

Discontinue drug immediately and notify physician at the first sign of a hypersensitivity reaction or side effects. Do not administer clinical dextran solution. Use epinephrine and/or antihistamines (diphenhydramine) as indicated. Resuscitate as necessary.

DEXTRAN HIGH MOLECULAR WEIGHT

(**DEX**-tran hi mo-**LEK**-u-ler)
Dextran 70, Dextran 75, Gentran 75
Plasma volume expander
pH 3 to 7

USUAL DOSE

Variable, depending on amount of fluid loss and resultant hemoconcentration. Initially 30 Gm (500 mL). Total dose should not exceed 1.2 Gm/kg (20 mL/kg) of body weight in the first 24 hours for adult and pediatric patients. May give 0.6 Gm/kg (10 mL/kg) every 24 hours thereafter if indicated. ***Use of Dextran 1 is indicated for prophylaxis of serious anaphylactic reactions in select patients; however, Dextran 1 is very limited in the United States.***

DILUTION

Available as a 6% solution in 500-mL bottles properly diluted in NS or D5W and ready for use. Dextran 70 (Cutter) is available in a 250-mL bottle. Use only clear solution. Crystallization of dextran can occur at low temperatures. Submerge in warm water and dissolve all crystals before administration.

Storage:

Store at constant temperature not above 25° C (76° F). Discard partially used solution; no preservative added.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. However, one source suggests that drugs should not be added to a dextran solution.

RATE OF ADMINISTRATION

Variable, depending on indication, present blood volume, and patient response. Initial 500 mL may be given at 20 to 40 mL/min if hypovolemic. If additional high molecular weight dextran is required, reduce flow to lowest rate possible to maintain hemodynamic status desired. In normovolemic patients, rate should not exceed 4 mL/min.

ACTIONS

A glucose polymer that approximates colloidal properties of human albumin. Provides hemodynamically significant plasma volume expansion in excess of the amount infused for about 24 hours. Dilutes total serum proteins and hematocrit values. Smaller dextran molecules are eliminated in urine; larger molecules are degraded to glucose.

INDICATIONS AND USES

Adjunct in treatment of shock or impending shock caused by burns, hemorrhage, surgery, or trauma.

Unlabeled uses:

Treatment of nephrosis, toxemia of late pregnancy, and prevention of postoperative deep vein thrombosis.

CONTRAINDICATIONS

Severe bleeding disorders; marked hemostatic defects (e.g., thrombocytopenia, hypofibrinogenemia), even if drug-induced (e.g., heparin, warfarin); known hypersensitivity to dextran; breast-feeding and pregnancy unless a lifesaving measure; severe congestive cardiac failure; renal failure.

PRECAUTIONS

For IV use only. ■ Used when whole blood or blood products are not available. Not a substitute for whole blood or plasma proteins. ■ Use extreme caution in heart disease, impaired hepatic or renal function, congestive heart failure, pulmonary edema, in patients with edema and sodium retention of pathologic abdominal conditions, and in patients receiving anticoagulants or corticosteroids.

Monitor:

Monitor pulse, BP, central venous pressure, and urine output every 5 to 15 minutes for the first hour and hourly thereafter while indicated. ■ Maintain hydration of patient with additional IV fluids; dextran promotes tissue dehydration. Avoid overhydration with dilution of electrolyte balance. ■ Change IV tubing or flush well with normal saline before infusing blood. Dextran will promote coagulation of blood in the tubing (glucose content). ■ May reduce coagulability of the circulating blood. Observe patient for increased bleeding; maintain hematocrit above 30%. ■ Hemoglobin, hematocrit, electrolyte, and serum protein evaluations are necessary during therapy. ■ 500 mL contains 77 mEq of sodium and chloride. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established.

DRUG/LAB INTERACTIONS

Draw blood for **laboratory tests and type and cross-match** before giving dextran, or notify laboratory of its use. May alter type and cross-match, blood sugar, total protein, and total bilirubin evaluation. ■ May produce elevated **urine specific gravity** (also symptom of dehydration) and increase **AST and ALT.** ■ See Monitor for interaction with blood.

SIDE EFFECTS

Bleeding, dehydration, fever, hypotension, joint pain, nausea, overhydration, tightness of the chest, urticaria, vomiting, wheezing. Severe anaphylaxis and death have occurred. Excessive doses have caused wound hematoma, seroma, and bleeding; distant bleeding (hematuria, melena); and pulmonary edema.

ANTIDOTE

Notify physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Use epinephrine and/or antihistamines (diphenhydramine) as indicated. Factor VIII infusion may reverse excessive bleeding. Resuscitate as necessary.

DEXTRAN LOW MOLECULAR WEIGHT

(**DEX**-tran lo mo-**LEK**-u-ler)
Dextran 40, Gentran 40, L.M.D. 10%, Rheomacrodex
Plasma volume expander
pH 3 to 7

USUAL DOSE

Adjunct in shock:

Variable, depending on amount of fluid loss and resultant hemoconcentration. Do not exceed 2 Gm/kg (20 mL/kg) of body weight total over first 24 hours and 1 Gm/kg (10 mL/kg) total over each succeeding 24 hours. Discontinue infusion after 5 days of therapy. ***Dextran 1 is indicated for prophylaxis of serious anaphylactic reactions in select patients; however, its availability is limited in the United States.***

Prophylaxis of venous thrombosis and/or pulmonary embolism:

10 mL/kg of body weight on day of surgery. 500 mL daily for 2 to 3 days, then 500 mL every 2 to 3 days up to 2 weeks. Length of treatment based on risk of thromboembolic complication. ***Note previous comment on use of dextran 1.***

As priming fluid:

10 to 20 mL/kg of body weight. Do not exceed this dose. May be used in conjunction with other priming fluids.

DILUTION

Available as a 10% solution in 500-mL bottles properly diluted in NS or D5W and ready for use. Use only clear solution. Crystallization of dextran can occur at low temperatures. Submerge in warm water and dissolve all crystals before administration.

Storage:

Store at constant temperature not above 25° C (76° F). Discard partially used solution; no preservative added.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. However, one source suggests that drugs should not be added to a dextran solution.

RATE OF ADMINISTRATION

Initial 500 mL may be given rapidly. Remainder of any desired daily dose should be evenly distributed over 8 to 24 hours depending on use. Slow rate or discontinue dextran for rapid increase of central venous pressure.

ACTIONS

A low-molecular-weight, rapid, but short-acting plasma volume expander. A colloid hypertonic solution, it increases plasma volume by once or twice its own volume. Helps to restore normal circulatory dynamics, increasing arterial and pulse pressure, central venous pressure, and cardiac output. Improves microcirculatory flow and prevents sludging in venous channels. Mobilizes water from body tissues and increases urine output.

INDICATIONS AND USES

Adjunctive therapy in the treatment of shock caused by hemorrhage, burns, trauma, or surgery. ■ Prophylaxis during surgical procedures with a high incidence of venous thrombosis and pulmonary embolism. ■ Pump priming during extracorporeal circulation.

CONTRAINDICATIONS

Severe bleeding disorders; marked hemostatic defects (e.g., thrombocytopenia, hypofibrinogenemia), even if drug-induced (e.g., heparin, warfarin); known hypersensitivity to dextran; breast-feeding and pregnancy unless a lifesaving measure; severe congestive cardiac failure; renal failure.

PRECAUTIONS

For IV use only. ■ Use caution in heart disease, renal shutdown, congestive heart failure, pulmonary edema, patients with edema and sodium retention, and patients taking corticosteroids.

Monitor:

Monitor pulse, BP, central venous pressure (if possible), and urine output every 5 to 15 minutes for the first hour and hourly thereafter while indicated. ■ Slow rate or discontinue dextran for rapid increase of central venous pressure (normal 7 to 14 mm H_2O pressure). ■ If anuric or oliguric after 500 mL of dextran, discontinue the dextran. Mannitol may help increase urine flow. ■ Maintain hydration of patient with additional IV fluids; dextran promotes tissue dehydration. Avoid overhydration and dilution of serum electrolytes. ■ Change IV tubing or flush well with normal saline before superimposing blood. Dextran will promote coagulation of blood in the tubing (glucose content). ■ May reduce coagulability of the circulating blood slightly. Observe for bleeding complications, particularly following surgery or if patient is being anticoagulated. Maintain hematocrit above 30%. ■ 500 mL contains 77 mEq of sodium and chloride. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established.

DRUG/LAB INTERACTIONS

Draw blood for **laboratory tests and type and cross-match** before giving dextran, or notify laboratory of its use. May alter type and cross-match, blood sugar, total protein, and total bilirubin evaluation. ■ May produce elevated **urine specific gravity** (also a symptom of dehydration) and increase **AST and ALT.** ■ See Monitor for interaction with blood.

SIDE EFFECTS

Bleeding, dehydration, fever, hypotension, joint pain, nausea, overhydration, tightness of chest, urticaria, vomiting, wheezing. Severe anaphylaxis and death can occur. Excessive doses have caused wound hematoma, wound seroma, wound bleeding, distant bleeding (hematuria, melena), and pulmonary edema.

ANTIDOTE

Notify the physician of any side effect. Discontinue the drug immediately at the first sign of a hypersensitivity reaction, provided other means of sustaining the circulation are available. Use epinephrine and/or antihistamines (diphenhydramine) as indicated. Factor VIII infusion may reverse excessive bleeding. Resuscitate as necessary.

DEXTROSE

(**DEX**-trohs)
Glucose
Nutritional (carbohydrate)
Antidote
pH 3.2 to 6.5

USUAL DOSE

Depends on indication for use; age, weight, clinical condition of the patient; and laboratory determinants. The average normal adult requires 2 to 3 L of fluid daily to replace water loss through perspiration and urine.

Treatment of hypoglycemia:

10 to 25 Gm (20 to 50 mL of 50% dextrose or 40 to 100 mL of 25% dextrose). Repeat as needed.

Nutritional support:

As part of a parenteral nutritional regimen that also includes amino acids, electrolytes, and possibly lipid emulsion. Dextrose dose is individualized to meet patient requirements.

Treatment of hyperkalemia (unlabeled):

25 Gm (50 mL of 50% dextrose) administered with 10 units of regular insulin over 5 to 30 minutes. Repeat as needed.

PEDIATRIC DOSE

Dose is dependent on indication for use, weight, clinical condition, and laboratory results.

Treatment of hypoglycemia:

0.5 to 1 Gm/kg/dose (2 to 4 mL/kg/dose of 25% dextrose). Do not exceed 25 Gm/dose. Repeat as needed. Subsequent continuous IV infusion of 10% dextrose may be needed to stabilize blood glucose levels. Further treatment should be guided by evaluation of the underlying disorder.

Nutritional support:

See Usual Dose.

Treatment of hyperkalemia (unlabeled):

0.5 to 1 Gm/kg (2 mL/kg of 25% dextrose) administered with regular insulin. Usual ratio is 1 unit of insulin for every 4 to 5 Gm dextrose. Repeat as needed.

See Rate of Administration, Precautions, Monitor, and Maternal/Child.

NEONATAL DOSE

Dose is dependent on indication for use, weight, clinical condition, and laboratory results.

Treatment of hypoglycemia in neonates and low-birth-weight infants:

0.25 to 0.5 Gm/kg/dose (1 to 2 mL/kg/dose of 25% dextrose); do not exceed 25 Gm/dose. Larger or repeated single doses may be required in severe cases or older infants. Subsequent continuous IV infusion of 10% dextrose may be needed to stabilize blood glucose levels. Further treatment should be guided by evaluation of the underlying disorder.

Nutritional support:

See Usual Dose.

See Rate of Administration, Precautions, Monitor, and Maternal/Child.

DOSE ADJUSTMENTS

Dosing should be cautious in newborns, especially premature infants with low birth weight, and in the elderly. Lower-end initial doses may be indicated. Consider decrease in organ function, concomitant disease, or other drug therapy. See Rate of Administration, Precautions, and Maternal/Child.

DILUTION

Available in several concentrations. Final concentration for administration will depend on indication for use. Depending on indication, may be given undiluted or further diluted to achieve desired concentration. Check label for aluminum content; see Precautions. Dextrose solutions are excellent media for bacterial growth. Do not use unless the solution is entirely clear.

Filters:

One manufacturer states, "Use of a final filter is recommended during administration of all parenteral solutions, where possible."

Storage:

Store at 20° to 25° C (68° to 77° F). Protect from freezing.

COMPATIBILITY

Will cause pseudoagglutination of red blood cells if administered simultaneously with whole blood. Consult pharmacist or refer to individual drug monograph before admixing with other drugs or solutions. Mix thoroughly.

RATE OF ADMINISTRATION

Rate dependent on concentration and indication for use. The maximum rate at which glucose can be infused without producing glycosuria is 0.5 Gm/kg/hr. At 0.8 Gm/kg/hr, 95% is retained and will cause glycosuria. For continuous infusions of concentrated dextrose, the administration rate should be governed by the patient's tolerance to dextrose, especially during the first few days of therapy. Increase rate gradually to the maximum required dose as indicated by frequent determinations of blood glucose levels. When discontinuing therapy, consideration should be given to gradually decreasing the infusion rate in the last hour to reduce the risk of hypoglycemia. Excessively rapid administration may cause hyperosmolar syndrome.

Excessive or rapid administration in very-low-birth-weight infants may cause hyperglycemia, increased serum osmolality, and possible intracerebral hemorrhage. Infusion rate and volume depend on the age, weight, and clinical and metabolic conditions of the patient and on concomitant therapy and should be determined by a consulting physician experienced in pediatric IV fluid therapy.

When higher concentrations are given peripherally, administer slowly (preferably through a small-bore needle into a large vein) to minimize venous irritation; see Precautions.

Do not hang flexible plastic containers in series connection, do not pressurize to increase flow rates without first fully evacuating residual air from the container, and do not use vented IV administration sets. All may result in air embolism.

ACTIONS

A parenteral fluid and nutrient replenisher. A monosaccharide, it provides glucose calories for metabolic needs. Metabolized to CO_2 and water. Its oxidation provides water to sustain volume and may help lower excess ketone production. Restores blood glucose levels. May help minimize liver glycogen depletion and may exert a protein-sparing action. Hypertonic solutions (20% to 50%) act as diuretics. When given in conjunction with insulin for the treatment of hyperkalemia, dextrose stimulates the uptake of potassium into cells, lowering serum potassium levels. Readily excreted by the kidneys, producing diuresis.

INDICATIONS AND USES

Parenteral replenishment of fluid and minimal carbohydrate calories (2½%, 5%, 10%). ■ Source of calories and fluid replenishment when mixed with amino acids or other **compatible** IV fluids for patients requiring parenteral nutrition when oral or enteral nutrition is not possible or is insufficient or contraindicated (10% to 70%). ■ Treatment of acute symptomatic hypoglycemia in the neonate or older infant (25%). ■ Treatment of acute symptomatic hypoglycemia or insulin hypoglycemia (hyperinsulinemia or insulin shock). ■ As a diluent for IV administration of medications (usually 2½% to 10% solutions).

Unlabeled uses:

Adjunctive treatment of hyperkalemia when administered concomitantly with insulin (25% or 50% solution).

CONTRAINDICATIONS

Known hypersensitivity to dextrose. Solutions containing dextrose may be contraindicated in patients with known allergies to corn or corn products. ■ Concentrated dextrose should not be used in severely dehydrated patients (may worsen hyperosmolar state) or in patients with intracranial or intraspinal hemorrhage, diabetic coma, or delirium tremens, especially if the patient is already dehydrated.

PRECAUTIONS

Administration of these solutions can cause fluid and/or solute overload, resulting in dilution of serum electrolyte concentrations, overhydration, congested states, or pulmonary edema. ■ If administered too rapidly, concentrated dextrose solutions may result in significant hyperglycemia and possible hyperosmolar syndrome characterized by mental confusion and loss of consciousness. Hyperglycemia is associated with an increase in serum osmolality, resulting in osmotic diuresis, dehydration, and electrolyte losses. Patients with underlying CNS disease and renal impairment who receive dextrose infusions may be at greater risk for developing a hyperosmolar hyperglycemic state. ■ Excessive administration of dextrose may result in significant hypokalemia and hypophosphatemia. ■ Use with caution in patients with subclinical or overt diabetes and in patients receiving corticosteroids. ■ Pulmonary embolism and pulmonary distress due to pulmonary vascular precipitates have been reported. Patients requiring calcium and phosphate supplementation may be at increased risk. However, precipitates have been reported even in the absence of phosphate salt in the parenteral solution. Precipitation after passage through an in-line filter and suspected in vivo precipitate formation have also been reported. ■ Use dextrose with extreme caution in newborns, especially premature or low-birth-weight infants. Risk of developing hypoglycemia or hyperglycemia is increased; see Monitor. Hypoglycemia in the newborn can cause prolonged seizures, coma, and brain damage. Excessive or rapid administration of dextrose may result in increased serum osmolality and possible intracerebral hemorrhage. Hyperglycemia has also been associated with late-onset bacterial and fungal infections, retinopathy of prematurity, necrotizing enterocolitis, bronchopulmonary dysplasia, prolonged length of hospital stay, and death. ■ Some solutions may contain aluminum. In impaired kidney function, aluminum may reach toxic levels. Premature neonates are particularly at risk because of their immature kidneys and requirement for calcium and phosphate, which also contain aluminum. Research indicates that patients with impaired renal function who receive greater than 4 to 5 mcg/kg/day of parenteral aluminum are at risk for developing CNS or bone toxicity associated with aluminum accumulation. ■ The development of hepatobiliary disorders in some patients without pre-existing liver disease who receive parenteral nutrition has been reported. Disorders may include cholecystitis, cholelithiasis, cholestasis, hepatic steatosis, fibrosis, and cirrhosis, possibly leading to hepatic failure. ■ Parenteral nutrition–associated liver disease (PNALD) has been reported in patients who receive parenteral nutrition for extended periods, especially preterm infants. May present as cholestasis or steatohepatitis. Exact etiology is unclear and may be multifactorial. ■ Concentrated dextrose solutions should not be withdrawn abruptly. May cause rebound hypoglycemia. Reduce rate of administration gradually and then follow with administration of 5% or 10% dextrose solution. ■ Patients who require parenteral nutrition are at high risk for infections. Risk is increased in patients with malnutrition-associated immunosuppression, hyperglycemia exacerbated by dextrose infusion, long-term use and poor maintenance of IV catheters, or immunosuppressive effects of other concomitant conditions, drugs, or other components of the parenteral formulation (e.g., lipid emulsion). ■ Refeeding severely undernourished patients may result in refeeding syndrome characterized by the intracellular shift of potassium, phosphorus, and magnesium as the patient becomes anabolic. Thiamine deficiency and fluid retention may also develop. To prevent these complications, slowly increase nutrient intake, including dextrose solution. ■ Hypersensitivity and infusion reactions, including anaphylaxis, have been reported. ■ Infusion of hypertonic solutions into a peripheral vein may result in vein irritation, vein damage, and/or thrombosis.

Monitor:

Type of laboratory monitoring depends on indication and may include baseline and periodic monitoring of CBC, renal and liver function tests, ammonia levels, serum glucose, and electrolytes. ■ Monitor changes in fluid balance, electrolyte concentrations, and acid-base balance during prolonged therapy or as indicated by patient condition. ■ Electrolytes, vitamins, and minerals are readily depleted. Watch for any signs of beginning deficiency and replace as needed. ■ A vesicant at concentrations greater than 10%. Ensure proper catheter or needle position, confirm patency of vein, and avoid extravasation. Administration through a central line is required for prolonged infusions of concentrations over 10% to 12.5% or for solutions with an osmolarity of approximately 900 mOsm/L or more. Routine monitoring of infusion site required. ■ Monitor blood glucose. Supplemental insulin may be required. ■ Monitor for S/S of hypersensitivity reactions (angioedema, bronchospasm, chills, cyanosis, fever, hypotension, pruritus, and rash). ■ Monitor for S/S of pulmonary distress. ■ Inspect the solution, infusion set, and catheter periodically for formation of precipitates. ■ Monitor for S/S of infection. ■ Monitor for S/S that may indicate refeeding syndrome (hypokalemia, hypophosphatemia, hypomagnesemia, CHF, edema). ■ See Rate of Administration and Precautions.

Pediatric patients:

Monitor fluid intake, urine output, and serum electrolytes closely. Small volumes of fluid may affect fluid and electrolyte balance in very small infants and neonates. Renal function may be immature and the ability to excrete fluid and solute loads limited. ■ Monitor serum glucose frequently in all pediatric patients but especially in infants, neonates, and low-birth-weight infants. Adequate glycemic control is imperative to avoid potential long-term adverse effects; see Precautions.

Pediatric Education:

Promptly report development of any adverse event, including but not limited to S/S of infection, pulmonary distress, hypersensitivity reactions, or pain at injection site.

Maternal/Child:

Category C: safety for use in pregnancy and breast-feeding not established. Malnutrition in pregnant women is associated with adverse maternal and fetal outcomes. Parenteral nutrition should be considered if a pregnant woman's nutritional requirements cannot be met by oral or enteral intake. Intrapartum maternal IV infusions of glucose-containing solutions may produce maternal hyperglycemia with subsequent fetal hyperglycemia and fetal metabolic acidosis. Fetal hyperglycemia can result in increased fetal insulin levels, which may result in neonatal hypoglycemia after delivery. Benefits must outweigh risks. Use caution and monitor fluid balance, glucose and electrolyte concentrations, and acid-base balance of both mother and child. ■ See Precautions and Monitor.

Elderly:

At increased risk for developing hyponatremia and hyponatremic encephalopathy. Lower-end initial doses may be indicated; see Dose Adjustments. Monitoring of renal function may be useful. Specific age-related differences in response have not been identified.

DRUG/LAB INTERACTIONS

See Monitor.

SIDE EFFECTS

Rare in small doses and at lower concentrations when administered at the appropriate rate. Side effects may include acidosis, alkalosis, aluminum toxicity, febrile reactions, fluid overload (congested states, pulmonary edema, overhydration, dilution of serum electrolyte concentrations), hepatobiliary disorders, hyperglycemia (during infusion), hyperosmolar syndrome (mental confusion, loss of consciousness), hypersensitivity reactions (e.g., anaphylaxis; coughing; difficulty breathing; periorbital, facial, and/or laryngeal edema; pruritus; sneezing; and urticaria), hypokalemia, hypophosphatemia, hypovitaminosis, infection, parenteral nutrition–associated liver disease, pulmonary embolism, rebound hypoglycemia (after infusion), refeeding syndrome, venous thrombosis or phlebitis.

ANTIDOTE

Discontinue the drug and notify the physician of the side effect. Provide symptomatic treatment as required. Dose reduction may be sufficient for management of some side effects. If signs of pulmonary distress occur, stop the infusion and initiate a medical evaluation. Patients developing signs of hepatobiliary disorders should be assessed by a clinician knowledgeable in liver disease. Treat hypersensitivity reactions as indicated (e.g., antihistamines, epinephrine, corticosteroids) and resuscitate as necessary.

DIAZEPAM BBW

(dye-**AYZ**-eh-pam)
Valium
Benzodiazepine
Sedative-hypnotic
Antianxiety agent
Anticonvulsant
pH 6.2 to 6.9

USUAL DOSE

Dose should be individualized. The usual recommended dose in older pediatric patients and adults is 2 to 20 mg IM or IV depending on the indication and its severity. In some conditions (e.g., tetanus), larger doses may be required. In acute conditions, the injection may be repeated within 1 hour, although an interval of 3 to 4 hours is usually satisfactory. Consider transition to oral therapy, if appropriate, once the acute symptomatology has been controlled.

Moderate anxiety disorders and symptoms of anxiety:

2 to 5 mg IV. Repeat in 3 to 4 hours if necessary.

Severe anxiety disorders and symptoms of anxiety:

5 to 10 mg IV. Repeat in 3 to 4 hours if necessary.

Acute alcohol withdrawal:

10 mg initially, then 5 to 10 mg in 3 to 4 hours if necessary.

Endoscopic procedures:

10 mg or less is usually effective given immediately before procedure begins; titrate to desired sedation (e.g., slurred speech). Up to 20 mg may be indicated if a narcotic is not used.

Muscle spasm:

5 to 10 mg. Repeat in 3 to 4 hours if necessary. Larger doses may be required in tetanus.

Status epilepticus and severe recurrent convulsive seizures:

5 to 10 mg. May be repeated at intervals of 10 to 15 minutes up to a total dose of 30 mg. May repeat in 2 to 4 hours. Another source suggests 0.15 to 0.2 mg/kg (maximum dose of 10 mg). May repeat one time.

Cardioversion:

5 to 15 mg 5 to 10 minutes before procedure begins.

PEDIATRIC DOSE

Safety for use in neonates not established but is used. Neonates and young infants have reduced or immature organ function; may be susceptible to prolonged CNS depression. Avoid small veins (e.g., dorsum of hand or wrist); see Monitor. Use in infants and children is most frequent in tetany and status epilepticus. Use of longer-acting anticonvulsants (e.g., phenobarbital, phenytoin) following diazepam may be indicated.

Tetanus in pediatric patients from 30 days of age to 5 years of age:

1 to 2 mg every 3 to 4 hours as necessary. Another source recommends a dose of 0.1 to 0.2 mg/kg/dose every 2 to 6 hours in infants and children, titrating as needed.
Respiratory assistance must be available.

Tetanus in pediatric patients 5 years of age or older:

5 to 10 mg every 3 to 4 hours as necessary. Respiratory assistance must be available.

Status epilepticus in neonates (unlabeled):

0.1 to 0.3 mg/kg/dose given over 3 to 5 minutes, every 15 to 30 minutes, to a maximum total dose of 2 mg (not recommended as first-line agent).

Status epilepticus in pediatric patients from 30 days of age to 5 years of age:

0.2 to 0.5 mg every 2 to 5 minutes to a maximum 5-mg dose. Another source suggests 0.1 to 0.3 mg/kg/dose given over 3 to 5 minutes every 5 to 10 minutes with a maximum dose of 10 mg for pediatric patients over 30 days of age.

Status epilepticus in pediatric patients 5 years of age or older:

1 mg every 2 to 5 minutes to a maximum 10-mg dose. May repeat in 2 to 4 hours if necessary.

DOSE ADJUSTMENTS

Lower doses (usually 2 to 5 mg) with slow titration should be used in elderly or debilitated patients and when other sedative medications are coadministered. ■ See Drug/Lab Interactions.

DILUTION

Do not dilute or mix with any other drug. Should be given directly into the vein. Inject into IV tubing close to vein site only when direct IV injection is not feasible. Consider heparin lock for frequent injection.

Storage:

Store at CRT in cartons to protect from light. Do not freeze.

COMPATIBILITY

Manufacturers recommend not mixing with any other drug or solution in syringe or solution. Precipitation can occur.

Other sources suggest a few specific **compatibilities** dependent on concentration and manufacturer; consult a pharmacist.

RATE OF ADMINISTRATION

Adults:

5 mg (1 mL) or fraction thereof over 1 minute. Maximum rate is 5 mg/min.

Infants and other pediatric patients:

Give total dose over a minimum of 3 minutes in a dosage not to exceed 0.25 mg/kg.

ACTIONS

A benzodiazepine that binds to benzodiazepine receptors on the postsynaptic GABA neuron. Acts on parts of the limbic system, the thalamus and the hypothalamus, and induces calming effects. Exerts antianxiety, sedative/hypnotic, amnesic, anticonvulsant, skeletal muscle relaxant, and antitremor effects. Diminishes patient recall. Metabolized in the liver; stays in the body in appreciable amounts for several days and is excreted very slowly in the urine. Crosses the placental barrier. Secreted in breast milk.

INDICATIONS AND USES

Relief of acute anxiety when rapid action is required. ■ Acute alcohol withdrawal (as an aid in symptomatic relief of acute agitation, tremor, impending or acute delirium tremens, and hallucinosis). ■ As an adjunct in (1) endoscopic procedures; (2) skeletal muscle spasms associated with local pathology, cerebral palsy, athetosis, stiff-man syndrome, and tetanus; and (3) status epilepticus and severe recurrent convulsive seizures. ■ As a premedication in patients undergoing surgical procedures (IM preferred) and cardioversion.

CONTRAINDICATIONS

Known hypersensitivity, acute narrow-angle glaucoma, and open-angle glaucoma unless receiving appropriate therapy.

PRECAUTIONS

Concomitant use of benzodiazepines and opioids (e.g., morphine, hydromorphone

[Dilaudid], fentanyl) may result in profound sedation, respiratory depression, coma, and death; see Drug/Lab Interactions. ■ Not recommended for treatment of petit mal or petit mal variant seizures; may precipitate tonic status epilepticus. ■ Patients may experience a return to seizure activity after initial control; re-administration of diazepam may be needed. Once seizures are controlled, consideration should be given to the administration of agents useful in longer-term control of seizures. ■ Avoid use in patients in shock, coma, or in acute alcoholic intoxication with depression of vital signs. ■ Use caution in the elderly, those who are very ill, and those with limited pulmonary reserve (e.g., chronic lung disease) or unstable cardiac status; may be at increased risk of apnea and/or cardiac arrest. ■ Withdrawal symptoms will occur after extended use. Gradual tapering of dose may be indicated. ■ Use caution in patients with impaired renal or hepatic function. ■ Intended for short-term use only. ■ Available PO and as a rectal gel.

Monitor:

See Dilution. ■ To reduce the incidence of venous thrombosis, phlebitis, or local irritation, avoid smaller veins (such as the dorsum of the hand or wrist) and administer injection slowly. Extravasation or arterial administration hazardous. ■ Oxygen, respiratory assistance, and flumazenil must always be available. ■ Monitor vital signs. ■ Monitor patients for respiratory depression and sedation, especially when used concomitantly with opioids and other CNS depressants; see Drug/Lab Interactions. ■ EEG monitoring may be useful for monitoring seizure activity. ■ Periodic CBC and liver function tests may be indicated with long-term use.

Patient Education:

May produce drowsiness or dizziness. Request assistance with ambulation and use caution performing tasks that require alertness. Do not drive or operate hazardous machinery until all effects have subsided. ■ Avoid use of alcohol or other CNS depressants (e.g., antihistamines, barbiturates). ■ May be habit-forming with long-term use or high-dose therapy. ■ Has amnesic potential; may impair memory. ■ Consider birth control options.

Maternal/Child:

Studies suggest an increased risk of birth deformities with use during pregnancy, especially in the first trimester. ■ Not recommended during pregnancy, childbirth, or while breast-feeding. ■ Efficacy and safety have not been established in neonates (30 days or less of age). ■ May contain benzyl alcohol, which has been associated with fatal gasping syndrome in premature infants.

Elderly:

See Dose Adjustments. Start with a small dose and increase gradually based on response. ■ More sensitive to therapeutic and adverse effects (e.g., ataxia, dizziness, oversedation). ■ IV injection may be more likely to cause apnea, bradycardia, hypotension, and cardiac arrest. ■ See Precautions and Drug/Lab Interactions.

DRUG/LAB INTERACTIONS

Concomitant use of **benzodiazepines and opioids** (e.g., morphine, hydromorphone, fentanyl) may result in profound sedation, respiratory depression, coma, and death. Reserve concomitant prescribing of these drugs for use in patients for whom alternative treatment options are inadequate. Limit dosages and durations to the minimum required, and monitor for S/S of respiratory depression and sedation. ■ When given concomitantly with a narcotic, the dosage of the narcotic should be reduced by at least one-third and administered in small increments. ■ Concurrent use with other **CNS depressants** (e.g., alcohol, antihistamines, barbiturates, MAO inhibitors, phenothiazines, tricyclic antidepressants) may result in additive effects. Reduced dose may be indicated. Monitor for S/S of respiratory depression and sedation. ■ May increase serum concentrations of **digoxin and phenytoin**; monitor serum levels. ■ **Ritonavir** may increase risk of prolonged sedation and respiratory depression. ■ Concurrent use with **beta-blockers, cimetidine, disulfiram, fluoxetine, isoniazid, itraconazole, ketoconazole, omeprazole**, and **probenecid** may inhibit hepatic metabolism, resulting in increased plasma concentrations of benzodiazepines. ■ May decrease effectiveness of **levodopa.** ■ Hypotensive effects of benzodiazepines may be increased by **any agent that induces hypotension** (e.g., antihypertensives, CNS depressants, diuretics, lidocaine, paclitaxel). ■ Use with **rifampin** increases clearance and reduces effects of diazepam. ■ **Theophyllines** (e.g., aminophylline) antagonize sedative effects of benzodiazepines. ■ **Smoking** increases metabolism and clearance of diazepam, decreasing plasma levels and sedative effects. ■ **Clozapine** has caused respiratory distress or cardiac arrest in a few patients; use concurrently with extreme caution. ■ **Grapefruit juice** may affect certain enzymes of the P_{450} enzyme system and should be avoided.

SIDE EFFECTS

Ataxia, drowsiness, fatigue, phlebitis, and venous thrombosis are the most commonly reported adverse reactions. Other reported reactions include apnea, blurred vision, bradycardia, cardiovascular collapse, changes in salivation, confusion, constipation, coughing, depressed respiration, depression, diplopia, dysarthria, dyspnea, headache, hiccups, hyperexcited states, hyperventilation, hypoactivity, hypotension, incontinence, jaundice, laryngospasm, nausea, neutropenia, nystagmus, rash, slurred speech, syncope, tremor, urinary retention, urticaria, and vertigo.

Overdose:

Diminished reflexes, coma, confusion, and somnolence.

ANTIDOTE

Notify the physician of all side effects. Reduction of dosage may be required. Discontinue the drug for major side effects or paradoxical reactions, including hyperexcitability, hallucinations, and acute rage. Flumazenil will reverse all sedative effects of benzodiazepines. A patent airway, artificial ventilation, oxygen therapy, and other symptomatic treatment must be instituted promptly. Monitor respiration, heart rate, and BP. May cause emesis; observe closely. Treat hypersensitivity reaction, or resuscitate as necessary.

DIAZOXIDE

(dye-az-**OX**-eyed)
Antihypertensive
(vasodilator)
pH 11.6

USUAL DOSE

1 to 3 mg/kg of body weight up to a maximum dose of 150 mg (10 mL). Another source suggests a dose of 50 to 100 mg. May be repeated every 5 to 15 minutes until an adequate response is obtained. Desired BP reduction should be achieved slowly over several hours to 1 to 2 days. Repeat as indicated at intervals of 4 to 24 hours to maintain desired BP. For short-term use until a regimen of oral antihypertensive medication is effective. Use for more than 4 or 5 days is rarely indicated. Do not use for more than 10 days.

Hypertensive emergency:

Applies to rare situations in which some BP decrease (not all the way to a normal range) is required to prevent or limit target organ damage. Examples are acute left ventricular failure with pulmonary edema, acute MI, dissecting aortic aneurysm, eclampsia, hypertensive encephalopathy, intracranial hemorrhage, unstable angina. Initial reduction in BP should be no greater than 25% within minutes to 2 hours. Within the next 2 to 6 hours, gradually reduce toward 160/100 mm Hg. Avoid excessive declines; may precipitate cerebral, coronary, or renal ischemia. Has been administered by continuous IV infusion at 7.5 to 30 mg/min (unlabeled).

Hypertensive emergencies of pregnancy (e.g., preeclampsia, eclampsia):

30 mg. Repeat every few minutes until an adequate response is obtained. See comments above and Maternal/Child.

PEDIATRIC DOSE

1 to 3 mg/kg of body weight up to 150 mg/dose. See instructions in Usual Dose and Maternal/Child.

DOSE ADJUSTMENTS

See Drug/Lab Interactions.

DILUTION

Should be given undiluted.

Storage:

Protect from light and freezing. Store at CRT.

COMPATIBILITY

Compatibility information not available from manufacturer; consult a pharmacist. See Drug/Lab Interactions.

RATE OF ADMINISTRATION

Rapidly as a single dose over 10 to 30 seconds. Not as effective when administered at a slower rate.

ACTIONS

A potent, rapid-acting, antihypertensive agent. Produces vasodilation by relaxing the smooth muscle of peripheral arterioles. Increases cardiac output while maintaining coronary and cerebral blood flow. Effects on renal blood flow not significant. Effective in patients not responsive to other antihypertensive agents. Acts within 1 to 5 minutes with a duration of 2 to 12 hours (range is 30 minutes to 72 hours). Usually no further decrease in BP after 30 minutes, but a gradual increase over the above duration to pretreatment levels. Crosses placental barrier; probably secreted in breast milk.

INDICATIONS AND USES

Severe hypertension (e.g., malignant and nonmalignant hypertensive emergencies).

CONTRAINDICATIONS

Compensatory hypertension (e.g., arteriovenous shunt or coarctation of the aorta), known sensitivity to thiazides or other sulfonamide-derived drugs (e.g., furosemide [Lasix], sulfamethoxazole/trimethoprim), labor and delivery. Not effective in pheochromocytoma.

PRECAUTIONS

Avoid rapid decrease in BP. May precipitate cerebral, coronary, or renal ischemia. Has caused angina and myocardial and cerebral infarction. ■ Use caution in patients with impaired cerebral or cardiac circulation. ■ Use with other antihypertensive agents may cause profound hypotension; see Drug/Lab Interactions.

Monitor:

Give only into a peripheral vein; avoid extravasation. ■ Maintain patient in recumbent position during injection and for at least 1 hour after injection. Should remain supine for 8 to 10 hours when used in conjunction with furosemide (Lasix). ■ Check BP every 5 minutes until stabilized and hourly thereafter. ■ Take BP with patient in standing position before ambulation. ■ Use caution in diabetes; monitor blood glucose levels. May cause hyperglycemia; difficult to assess. ■ Diuresis may be required to reverse sodium and water retention before diazoxide can be effective. Causes sodium and water retention and may precipitate edema and CHF. ■ May cause hyperuricemia; difficult to assess. ■ See Drug/Lab Interactions.

Maternal/Child:

Category C: safety for use in pregnancy, breast-feeding, and pediatric patients not established. ■ Has been used in preeclampsia and eclampsia. Use restricted to situations in which delivery is imminent or more commonly used agents (e.g., hydralazine) have not been effective. ■ See Contraindications. May stop uterine contractions if given during labor. Oxytoxics may be required. ■ May produce fetal or neonatal hyperbilirubinemia, thrombocytopenia, altered carbohydrate metabolism, and other adverse reactions if given before delivery. ■ Discontinue breast-feeding.

DRUG/LAB INTERACTIONS

Potentiates **coumarin** and its derivatives; a reduced dose of anticoagulant may be required. ■ May increase hypotensive, hyperglycemic, and hyperuricemic effects of **thiazides and other diuretics** (e.g., furosemide [Lasix]); see Monitor. ■ May decrease **phenytoin** (Dilantin) levels, reducing anticonvulsant effect. ■ Do not administer within 6 hours of **beta-adrenergic blocking agents** (e.g., atenolol [Tenormin], propranolol [Inderal]), **hydralazine, methyldopate, minoxidil** (Loniten), **nitrites, prazosin** (Minipress), **reserpine, or papaverine-like compounds.** Profound hypotension will result. ■ Use with **sulfonylureas** (e.g., tolbutamide) may cause hyperglycemia. ■ Interferes with **assessment of hyperglycemia and hyperuricemia.** ■ Will cause a **false-negative insulin response to glucagon.**

SIDE EFFECTS

Abdominal discomfort, cerebral ischemia, confusion, congestive heart failure, convulsions, edema, flushing, headache, hyperglycemia, hypotension (severe), ileus, light-headedness, myocardial ischemia, nausea, orthostatic hypotension, palpitations, paralysis, sensations of warmth, sensitivity reactions, sodium and water retention, supraventricular tachycardia, sweating, vomiting, weakness.

ANTIDOTE

Notify the physician of all side effects. Some will subside spontaneously; others will require symptomatic treatment. Treat sensitivity reaction as indicated and resuscitate as necessary. If hypotension occurs, place patient in a Trendelenburg position. Treat undesirable hypotension with dopamine or norepinephrine (Levophed); if no response, diazoxide is probably not the cause of the hypotension. Excessive hyperglycemia may be treated with insulin. Hemodialysis or peritoneal dialysis may be required in overdose.

DIFELIKEFALIN

(dye-FEL-i-KEF-a-lin)
Korsuva
Kappa opioid receptor agonist

USUAL DOSE

0.5 mcg/kg IV into the venous line of the dialysis circuit at the end of each hemodialysis session.

PEDIATRIC DOSE

Not established

DOSE ADJUSTMENTS

Renal:

No dosage adjustments are provided by the manufacturer.

Hepatic:

No dosage adjustments are provided by the manufacturer, although they should be avoided in severe hepatic impairment.

DILUTION

IV Bolus:

Withdraw required volume from vial(s) into syringe. No further dilution is required. Discard any unused portion**.**

COMPATIBILITY

Do not administer simultaneously with any other medication or IV solutions other than normal saline.

RATE OF ADMINISTRATION

Give via IV bolus into the venous line of the hemodialysis circuit at the end of hemodialysis. Blood should not be circulating through the dialyzer. Give during or after the rinse back of circuit. If given after rinse back, flush with at least 10 mL of normal saline.

ACTIONS

Difelikefalin is a kappa opioid receptor agonist; the mechanism of action for pruritus has not been established.

INDICATIONS AND USES

Treatment of moderate to severe pruritus associated with chronic kidney disease in adults undergoing hemodialysis; has not been studied for peritoneal dialysis.

CONTRAINDICATIONS

None is listed by the manufacturer.

PRECAUTIONS

CNS effects include dizziness, mental status changes, gait disturbances, somnolence, and falls. Dizziness and somnolence are most likely to occur during the first few weeks of therapy and may diminish with continued dosing. Patients must be cautioned about driving or operating machinery. Risk of CNS sedative effects may be increased with use of concomitant CNS depressants.

Monitor:

Mental status and relief of itching.

Patient Education:

May cause CNS depression; advise patient to take fall precautions and avoid driving or operating machinery while taking. Notify provider of signs of allergic reaction.

Maternal/Child:

There are no adequate data on developmental risks associated with the use in pregnant or lactating women.

Elderly:

Somnolence is increased in patients greater than 65 years of age.

DRUG/LAB INTERACTIONS

Difelikefalin may enhance CNS depressant effects of other CNS depressant drugs.

SIDE EFFECTS

Hyperkalemia, diarrhea, nausea, falling, altered mental status

ANTIDOTE

There is no antidote.

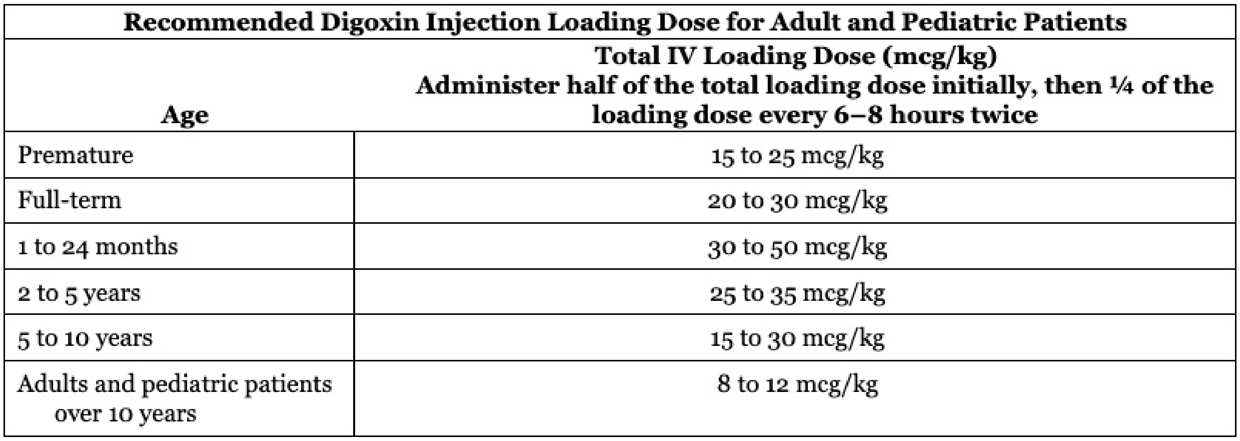
DIGOXIN

(dih-**JOX**-in)
Digoxin Pediatric, Lanoxin, Lanoxin Pediatric
Cardiac glycoside
Antiarrhythmic
Inotropic agent
pH 6.8 to 7.2

USUAL DOSE

Individualize dosing, taking into account factors that affect digoxin blood levels (e.g., lean body weight [LBW], CrCl, age, concomitant disease states, concurrent medications). In general, the dose of digoxin used should be determined on clinical grounds. Dosing can be either initiated with a loading dose followed by maintenance dosing (if rapid titration is desired) or initiated with maintenance dosing without a loading dose.Parenteral administration of digoxin should be reserved for when rapid digitalization is medically necessary or when the drug cannot be taken orally. When changing from IV to oral dosing, increase oral dose by 20% to 25% to allow for reduced bioavailability of the oral product.

Loading dosing regimen in adults and pediatric patients:



Recommended Digoxin Injection Loading Dose for Adult and Pediatric Patients	
Age	**Total IV Loading Dose (mcg/kg) Administer half of the total loading dose initially, then ¼ of the loading dose every 6–8 hours twice**
Premature	15 to 25 mcg/kg
Full-term	20 to 30 mcg/kg
1 to 24 months	30 to 50 mcg/kg
2 to 5 years	25 to 35 mcg/kg
5 to 10 years	15 to 30 mcg/kg
